region. Two glands the size of peas, containing caseous substance, and two normal to the naked eye were emulsified and inoculated into two guinea-pigs. No tubercle bacilli were found in the emulsion on microscopic examination. One of the guinea-pigs was killed 33 days after inoculation, and showed slight general tuberculosis. The other, killed 206 days after inoculation, showed enlargement and fibrosis of lymphatic glands, two grey tubercles in the spleen, chronic fibroid tuberculosis of a testis and epididymis, and no disease elsewhere. A culture isolated from the first guinea-pig produced on the differential media the luxuriant growths of the human type of tubercle bacillus. A rabbit inoculated subcutaneously with 15 mgm. of the culture and killed 144 days later showed a local lesion only. Three guinea-pigs were inoculated subcutaneously, each with 0.1 mgm. of the culture. One died prematurely in 68 days, and showed slight general tuberculosis. Another died in 130 days of chronic general tuberculosis of mild type, the lesions in the organs and the glands showing little or no necrosis or caseation. The third guinea-pig was killed 132 days after inoculation, and was found to have slight retrogressive tuberculosis, the abdominal and thoracic glands were slightly enlarged and fibrotic, the spleen contained a calcareous tubercle, and there were a few grey tubercles in the liver.

The results of the inoculation of guinea-pigs with original material and culture indicated that the virus was of lower virulence than standard human viruses.

CASE 124.—Female, aged 13 years, with cervical adenitis and an abscess in the muscles of the thigh. The patient was admitted to hospital in June, 1915, suffering from enlarged softened glands and sinuses in the neck. There was also an extensive abscess in front of the left hip-joint, which developed subsequent to the adenitis and before her admission to hospital. This abscess was intermuscular; it was not connected with the joint and there was no evidence of true hip disease. The thigh abscess and the neck abscesses were treated by aspiration. The girl was discharged in November, 1915, when there was no evidence of active tubercle. The thigh abscess had been successfully aspirated and no signs of it remained. The sinuses in the neck were all healed and there were no active glands.

*Investigation of material from the neck.*—Pus from a sinus and a cervical gland caused typical tuberculosis in guinea-pigs, and yielded cultures with the cultural characteristics of the human type of tubercle bacillus. One of the strains exhibited slight virulence for the rabbit.

*Investigation of material from the thigh abscess.*—No tubercle bacilli were found in a smear preparation of the pus of this abscess, but direct cultures were obtained, about a dozen colonies of tubercle bacilli appearing on each of three egg tubes. Two guinea-pigs inoculated intraperitoneally with the pus increased in weight, and when killed 262 days after inoculation showed very slight retrogressive tuberculosis. There was no omental or peritoneal tuberculosis; the inguinal and iliac glands were slightly enlarged and fibrotic, and in one guinea-pig there was retrogressive tuberculosis of an epididymis.

The culture isolated directly from the pus grew on serum and glycerine media with the characteristic luxuriance of the human type of tubercle bacillus. A rabbit inoculated subcutaneously with 20 mgm. of the culture developed a local lesion only. Three guinea-pigs were inoculated subcutaneously, each with 0.1 mgm. of the culture. One died in 168 days, and showed chronic general tuberculosis of fibroid type. The other two were killed 216 days after inoculation. In one tuberculosis was confined to the glands adjacent to the site of inoculation. In the other there were, in addition to local tuberculosis, scattered grey tubercles in the liver and one tubercle in the spleen.

The experiments on the guinea-pig with original material and culture demonstrated conclusively that the tubercle bacilli from the thigh abscess were of definitely lower virulence than standard human tubercle bacilli.

CASE 116.—Male, age 11 years, with tuberculosis of cervical glands. Material from this patient was received on two occasions. The first material was a dressing taken from a sinus in the neck on Feb. 19th, 1915. The second was pus aspirated on March 5th, 1915, from a cervical gland abscess. Three guinea-pigs were inoculated, two with sinus pus and one with aspirated pus. Typical, though not severe, general tuberculosis was produced in all three guinea-pigs. Two strains of culture were isolated, one through the guinea-pig from the sinus pus, the other directly from the aspirated pus. The cultural characteristics of the two strains were identical. On serum and glycerine serum they produced good growths, with yellow pigment. On glycerine agar, after a month or six weeks, there were thin dull-grey layers composed of microscopic colonies; on further incubation numerous whitish warty colonies appeared, some of which attained the size of millet seeds. On glycerine-potato thin, finely granular grey layers were produced, in which raised colonies of diverse form subsequently developed. No growth was obtained on glucose or glycerine broth. The cultural characteristics of both strains were unaltered.

by subculture on glycerine serum (12 and 14 subcultures). Three rabbits were inoculated subcutaneously, two with 10 mgm. of the direct strain and one with 30 mgm. of the guinea-pig strain. They were killed 99 to 110 days later and showed cystic caseous lesions and one or two small tubercles in the lungs; in each of two rabbits the scapular glands were also slightly tuberculous. A culture recovered from one of the rabbits was identical with the original culture and proved of low virulence for two rabbits inoculated subcutaneously.

*Summary of characteristics of virus.*—Cultures eugenic on (bovine) serum and glycerine serum, dysgenic on glycerine agar, potato, and broth. Virulence for guinea-pigs and rabbits that of the human type of tubercle bacillus.

Of the three strains, the properties of which are described above, two were identical in cultural characteristics with the human type of tubercle bacillus, but they differed from standard human strains in their relatively low virulence for the guinea-pig. These two strains, therefore, exhibit the attenuation of virulence which has hitherto appeared peculiar to the majority of lupus strains, and are the only such strains which have so far been obtained in this country from human tuberculous lesions other than those of lupus. The third strain had the virulence of standard human tubercle bacilli, but did not correspond exactly either to the human or to the bovine type of tubercle bacillus in cultural characteristics. Strains identical in every respect with this strain have recently been found in the sputum of phthisical persons and in cases of human bone and joint tuberculosis<sup>1, 2, 3</sup>.

## II. Statistical Data.

In my first series of cases cultures of tubercle bacilli were obtained from 71 persons suffering from glandular tuberculosis. Of these 71 cases, 68 were believed to be primary in the cervical glands; 1 was a case of cervical gland tuberculosis, probably secondary to pulmonary tuberculosis;

TABLE II.—Clinical Particulars of Each Case and Bacteriological Results.

No. of cases.	Date of receipt of material	Patient's place of residence.	Patient's sex and age in years.	Description of original material.*	Classification of cultures isolated.

\* Except where otherwise stated the material was taken from glands of the neck.

and 2 were cases of axillary gland tuberculosis. In the present series 35 cases have yielded cultures: of these, 34 were cases of primary cervical gland tuberculosis, and 1 was a case of axillary gland tuberculosis. There are in all, therefore, 102 cases of primary cervical gland tuberculosis upon which to base statistics as to the relative frequency of different types of tubercle bacilli in this form of human tuberculosis.

Table III. gives the proportion of the different types of tubercle bacilli found at various age-periods in this series of 102 cases.

TABLE III.

\* An attenuated "human" culture was obtained from a thigh abscess of one of these cases.

The figures show that in childhood cervical gland tuberculosis is caused more frequently by the bovine than by the human type of tubercle bacillus, nearly three-quarters (72·1 per cent.) of the cases in children under 10 years of age having yielded bovine tubercle bacilli. In persons over 10 years of age infection of human origin is more common, bovine infection accounting for about a third of the cases in the 10-20 years age-period and for rather less than a fifth of the cases in persons over 20 years of age.

The material used in my investigation of cervical gland tuberculosis has been derived mainly from cities and towns in England and Scotland, and, while the cases from the different localities are too few for comparative statistical purposes, it is noteworthy that a proportion of the cases from each centre of population has yielded tubercle bacilli of bovine type. If the figures for the whole of England are compared with the combined figures for Scotland, it is found that the proportion of bovine infections in children under 10 years of age is about the same for the two countries (in my first series the English percentage figure was lower than the Scotch). In persons over 10 years, on the other hand, the proportion of cases in which the infection was "bovine" is much higher in the Scotch than in the English series. The Scotch data are, however, too scanty to form a basis for inference. The figures for the two countries are set out in Table IV.

TABLE IV.

—	No. of cases.	Human	Bovine	Per-cent-age bovine.	5-10 years	Human	Bovine	Per-cent-age bovine.
					Under 10 years.			
Scotland ...	11	3	8	72·7	6	2	4	66·6
England ...	30	8	22	73·3	51	39*	12	23·5

\* Including 2 cases which yielded atypical cultures.

Of the 4 cases of cervical gland tuberculosis not accounted for in Table IV. 2 came from Wales, 1 from Ireland, and 1 from Orkney. Bovine tubercle bacilli were obtained from 1 (Welsh) case, human tubercle bacilli from the other three. Three cases of axillary gland tuberculosis yielded one "bovine" strain and two "human" strains.

## NOTES ON 73 CASES OF CEREBRO-SPINAL FEVER.

BY SHEFFIELD NEAVE, M.R.C.S., M.R.C.P. LOND.,  
TEMPORARY CAPTAIN, R.A.M.C.

THESE cases included all those occurring in East Suffolk, both civil and military, during the epidemic period of 1915-16, from Nov. 19th to August 14th. Except two, they all occurred within a radius of 20 miles in towns, barracks, and camps, as opposed to the country, and these were in small cottages where air-space per head was singularly deficient. None occurred in private houses of any size. They were treated at four centres conveniently situated for the areas connected with them. The average mortality was 44.2; average age 17.2 years: 8 cases under 5 years, 10.95 per cent., 57 cases between 5 and 25, 78.1 per cent., 8 cases over 25, 10.95 per cent. Maximum age, 56 years; minimum, 9 months.

*Etiology.*—There was a very close parallel in the rise and fall of the number of cases during the season of the epidemic in this district to that published by the Local Government Board of the cases in the British Isles, excluding military cases. As each month progressed the two curves followed each other closely. Our knowledge of the seasonal nature of so many diseases, including cerebro-spinal fever, is in a very unsatisfactory state, and the inclination of so many to be satisfied with the statement that in summer it is the higher temperature and in winter the lower temperature that accounts for it, does not tend towards further investigation of what is now an important mystery. Plants have their season, being, no doubt, adapted by selection, but it is difficult to see the connexion between the season and micro-organisms in the same way.

In this case the weather was undoubtedly different in different parts of the country and the *post hoc* cannot be considered proved as a *propter hoc*. The fact that colds are more prevalent in winter and that meningococcus specially affects the naso-pharynx does not give an adequate explanation of this correspondence of cases. Very few cases begin with catarrh.

An exception to the above parallel was that the epidemic here closed with a number of mild cases, finishing in the middle of August with an outbreak of 19 cases in 26 days, as described in THE LANCET of Dec. 30th last by Fleet-Surgeon T. D. Halahan. This, it might be argued, was caused by the hotter weather increasing the activity of the organism as is stated in respect of typhoid and diphtheria with their autumnal season, but surely this would militate against the winter theory.

Except in two instances, only one case came from the same house, notwithstanding that there was overcrowding in several instances, but this did not hold good in the case of large dormitories. From one small tenement three small children of 6, 4, and 3 years of age died of a fulminating form of the disease, only living a few hours after onset. From another similar dwelling a boy died within seven days, while his sister had a slight attack.

Weather, fatigue, and exposure do not seem to be important factors in the etiology of this disease.

A large Government training establishment in this district gave great opportunity for studying the etiology of the disease if time had permitted. Cases seem to crop up throughout the year at intervals of about two months or less with an exacerbation at the end of the epidemic season. The general character of the disease was very mild here and the death-rate very low compared to the other centres of infection, and considerably lowered the mortality of the whole. In July and August, when the epidemic had abated in the country generally, a number of cases occurred of a character so mild and transient that 7 out of the last 10 were only clinically diagnosable for a few days and no bacteriological confirmation was possible and yet out of the remaining 3 there were 2 deaths. During this outbreak a bacteriologist was specially sent to take charge.

The sanitary conditions are excellent, both with regard to ventilation and all other matters. It would appear that the organism increases in virulence when it has the opportunity of passing from naso-pharynx to naso-pharynx among a collection of young people, which is, according to present lights, the most favourable soil for its growth, and that this

is even more a factor than the accessory point of ventilation of buildings, the importance of which is demonstrated by the fact that the disease is seldom acquired in the trenches. It would seem, therefore, that if a number of young naso-pharynges are collected in any building, however well ventilated, the organism will succeed in transferring itself and increasing in virulence. This also seems to be much enhanced where the said young population is a floating one, a large proportion going and others taking their place, and so giving a greater variety and quantity of soil in which to grow.

In the matter of incubation period this outbreak was also instructive. Many of the cases had just returned from leave or were newcomers, and in analysing the facts as to where they had been on leave it was shown that the localities were distributed in many parts, and there was nothing to show infection while away. Thus there were 2 cases which fell ill one day after return, 3 two days, and 3 seven days. This would tend to show that incubation may in some cases be only one day before clinical symptoms appear.

*Symptoms.*—The most prominent details of the disease vary much in different cases. At each centre of the disease in the above list it was observed that there was often a similarity in the most pronounced symptoms, and when a number of cases were admitted near together in time the prominent details of the disease were much alike, as if the particular strain of organism had a special effect.

In the same way it may be observed that the intensity of the disease was very different at different centres, as shown by the highest and lowest death-rates being 77.7 and 14.8 per cent. Owing to the impossibility of doing routine agglutinations, it was not possible to ascertain how far the above facts could be explained by the various strains shown to exist.

Incontinence of urine and faeces was common, usually following on retention of urine. Meningococcus was twice found as a cause of the accompanying cystitis, but when the prevailing organism was sought for late in the bladder trouble it was not found, but in its place usually coli or a staphylococcus, and these were very obstinate and difficult to eradicate. In 3 cases there was severe pain in both sides of the chest and in 2 in the abdomen, as if corresponding to the dorsal nerves from definite vertebrae, as in herpes and Pott's disease. In another case there was severe pain in the arms and in another at the anus, but none lasted more than three days.

A number had a difficulty in swallowing, which necessitated nasal feeding, while others had an obstruction to respiration with stridor, which obtained during sleep and woke the patient up, when the obstruction desisted, but was immediately repeated on again falling asleep. This occurred in bad cases.

There was one case of pneumococcal pneumonia accompanying the disease, as mentioned by Osler as being common in a New York epidemic.

Dilatation of the pupil was not frequent, and it usually reacted to light. Only 2 cases of photophobia occurred, where there was no conjunctivitis as well. The specific coccus was found in one case of conjunctivitis. The patient was seldom peevish, but could usually be roused from coma to make a reply. He seldom, when recovered, recollects the awful discomfort he appeared to be suffering.

One case—a child of 10—was seized late in a very typical attack with total flaccid paralysis of both legs, resembling that of anterior poliomyelitis, which has remained for many weeks. Incontinence of urine and faeces has also remained. She is still very slowly improving. Poliomyelitis may have here followed on the meningococcal attack.

Two cases of haematuria occurred. Only one case of rash attributable to serum occurred and only a small percentage of cases had a rash at all. No case with haemorrhagic patches recovered.

Fulminating and severe sthenic cases ending in early death numbered 18, exclusive of 2 which aborted. Chronic cases were 6 in number and mild cases 27. The remaining 22 were of an intermediate type not coming under these heads.

*Diagnosis.*—The facies of a fulminating or severe case at onset was almost diagnostic, as well as a peculiar smell. In testing for Kernig's sign pain was frequently elicited at the hip-joint and not at the knee-joint.

At quite the commencement of the disease a useful sign was found to be the inability to put the chin on the chest, and this sign was also often found to be the last to be lost of the head and neck signs, though stiffness of the lower portion of the spine and Kernig's sign usually had a longer duration.

**Agglutination.**—No agglutinating sera were available till the middle of the epidemic, and little could be done in this way. At first it was attempted to keep the coccus alive until time could be made to organise the process, but many failures resulted after long subcultivation. Later emulsions were made and these were kept until July, when the tests were done.

Twenty-two cultivations from cases were tested and gave the following results:—

No. 1 serum agglutinations ...	3 emulsions tested gave a positive result.
" 2 "	" ... 4 "
" 3 "	" ... 14 "
" 4 "	" ... 1 "

and two emulsions were not agglutinated by any of the four sera. In four of the above cases No. 1 serum agglutinated the same emulsion as No. 3 serum, but to a much lower dilution.

**Treatment.**—This presents the gravest difficulties. The variability of the disease in intensity prevents one distinguishing between *propter hoc* and *post hoc*. Thus, as an epidemic proceeds, the disease is reduced in virulence, and a practitioner having changed his remedies used at first when there was a high death-rate, attributes the lower death-rate to this change. Again, an epidemic in one place may take a very mild form, although only a few miles from another where the death-rate is high, as instanced above, and the practitioner is apt to think that it is due to his remedies—e.g., a different serum from that of his neighbour.

The cases under review were treated: 1. By lumbar puncture until the amount of fluid coming away was reduced to 20 c.c. or lower. It was usually done several days running at the commencement of the disease, and later every other day, till the above result was obtained or the patient much improved. There is no doubt as to the benefit obtained by this treatment.

2. By the intrathecal injection of 0·5 per cent. carbolic acid in normal saline, which was allowed to run out again, thereby constituting a form of lavage. No improvement could be definitely traced to this treatment; but where there was pain a great deal was got rid of in this way, and it was thought therefore to be beneficial in those cases.

3. By the intrathecal injection of serum. In a few cases at first Burroughs and Wellcome's and Mulford's brands were used, and at Shotley the serum from the Pasteur Institute, but by far the larger number were treated with the serum from the Lister Institute. Both the latter were made from Gordon's strains. This serum injection seemed to have no effect whatever.<sup>1</sup>

4. Soamin and vaccines were used in a few cases; neither appeared to do any harm or good.

5. Intramine was used in 2 cases with unsatisfactory results.

6. Tartrate of antimony was exhibited in 9 cases. In 6 cases it was injected intravenously. In one of these the patient had had a period of three weeks' daily remitting temperature characteristic of septicaemia after the main symptoms of the nervous system had subsided. Within 48 hours of a single injection the temperature became normal and remained so with an uninterrupted recovery.<sup>2</sup> The second case was similar but the remitting temperature had not continued so long. It was also given in 2 fulminating cases which aborted a few hours afterwards in a remarkable way. In 2 other cases it appeared to have no effect on the course of the disease, both patients dying, although in one of them the temperature was always lowered after injection.

It is hoped that this remedy thus applied will prove useful at any rate in septicaemic conditions both in this disease and generally. In 4 cases, including one of the unsuccessful intravenous cases, a very small dose was given intrathecally, but there was no evidence of its having any effect. The spinal fluid was tested two days after the

injection for antimony without any being found, showing it had already been excreted. This was done by Miss Gladys Cobbold, of Girton College, who kindly consented to give her time for the purpose.

#### Procedure.

Patients were removed to one of the hospitals either before or after first lumbar puncture, and it is desired here to thank those in charge of them for their permission and assistance in studying these cases. The puncture fluid was carried in a case in the bonnet of the motor, which kept it at from 30° to 35° C. until the laboratory was reached. One or two nasgar tubes were inoculated at the same time when the fluid was collected and carried in the same way.

**Lumbar puncture.**—The points observed in respect of this operation, which was done not less than 153 times, are as follows. 1. It is more important to work by the sense of touch than by the eye. The following was the method adopted: Two fingers of the left hand are laid on the ilium and two above it on the side of the patient; this puts the thumb in a good position to be placed between the spinous processes of the correct two vertebrae, and so gives a sense of position and direction not otherwise obtainable. The thumb then draws the skin upwards to render it more tightly stretched than is normal, the object being to prevent the skin slipping away from the point chosen for puncture by the rather blunt needle which is best to use, and so causing it to enter elsewhere than intended. If this operation is thus performed it does not matter on which side the patient lies. 2. It is quite safe to puncture in all three of the second, third, and fourth lumbar spaces. 3. In some cases no fluid may exist in the theca that can be drawn off, owing probably to inspissation, more especially after frequent puncture in severe cases. Here it is useful to inject normal saline and let that return through the same needle or through another in a space below. A turbid fluid is thereby obtained consisting of washings of inspissated pus, which are useful for cultivation and microscopic investigation, besides getting rid of objectionable material. This process is also useful in the cadaver.

The very slow injection of fluids by gravity—e.g., 1 c.c. per minute (Horder)—appeared quite unnecessary. It seems to be safe to inject slowly with a syringe while watching respiration and desiring if a change in rapidity makes its appearance. This change is usually a diminution. When a given amount has been injected in this way, and no effect has been noticed on the respiration, and has been allowed to run out again, it is safe to inject a similar amount a second time rather faster. On one occasion only 15 c.c. of cerebro-spinal fluid came away, and the injection of only 10 c.c. of saline caused a slowing of respiration. This again occurred exactly at the same point every time saline was injected again, after being allowed to run out, showing pressure probably on the respiratory centre in a case where the foramen of Magendie was obstructed.

No bad results were obtained from lumbar puncture or injection either immediately or later, but in the case of what turned out to be brain tumour and another with pneumonia there were difficulties in consequence of the general anaesthetic.

**Cerebro-spinal fluid.**—The most common contamination was due to *staphylococcus albus*, although the skin was carefully prepared with spirit or ether and iodine before puncture. This organism gave a good deal of trouble.

The fluid was searched for meningococcus by examining a film of the deposit stained by Gram's method, and where no growth on nasgar was obtained this was considered sufficient where clinical symptoms were undoubted.

The meningococcus was obtained by cultivation in 36 out of 55 cases, where it was seen in the purulent sediment of the fluid. In one case no organism was seen in the fluid, but a cultivation was successful.

In one case no organism was found in the first place, but a cultivation was obtained from the fluid during a relapse a month later.

In 10 cases the organism was not found, and here the probabilities of a positive diagnosis lay in the clinical tests for meningitis generally, the cytology of the fluid and the clinical symptoms.

In addition to the above there were 8 similar cases where the fluid was not examined in this laboratory, the bacteriologist at Shotley on his arrival taking them in hand.

<sup>1</sup> Probably due to the serum not having been made with Nos. 3 and 4 types.

<sup>2</sup> First dose 1·5 c.c. of a 2 per cent. solution, to be increased gradually to 6 c.c. if necessary in later doses.

In one case, while the fluid was clear and no organism was found in it, it was found in a throat-swab.

An excess of lymphocytes was several times found in a clear fluid that later became purulent.

It was remarkable how few cocci were found as a rule in a smear, and their number had no relation to the state of the pus cells whether degenerated or in good preservation. The pus often seemed to contain nothing but mononuclear or degenerated cells, but after a long search a large area of polymorph-nuclear cells was nearly always eventually found, showing that the mixture of cells was not on regular lines.

In one case the meningococcus was found alive in the fluid after it had been in the incubator for 23 days, but as a rule the organism was very difficult to keep alive on any media more than half that time. It was found that the fluid drawn from the cisterna magna after death for diagnosis gave better information than that from the lumbar region both in the case of cerebro-spinal fever and tubercular meningitis.

The amount of cerebro-spinal fluid in a normal adult is variously stated at 60 c.c. and 200 c.c., but on one occasion a surplus of 75 c.c. was taken from a baby of 9 months with normal measurement of the head, and this without undue depression of the fontanelle. No harm ever resulted from allowing the flow to continue until normal pressure was reached.

In 16 positive and 2 doubtful cases the fluid remained clear; all these were mild cases which recovered.

*Contacts.*—In taking swabs it was found best to abstain from using a tongue depressor, and that if the patient was induced to continue saying "ah," it was easy to introduce West's swab without discomfort to him.

Before inoculating the plates it was found necessary to wipe the glass tube carefully, so as to remove any secretion and to prevent any organisms from the mouth being sown and any inhibition of growth by saliva. Another method was to withdraw the wire upwards for inoculation. The plates received four or five drops of fresh serum and the swab was placed in these when being applied to the surface.

It was remarked that where the contacts had been living together the same flora appeared to a great extent, also that there are usually not more than two kinds of organism on the plate showing the selective nature of the part.

It was only possible for want of time to carry out the 23° incubator and sugar tests. The latter gave trouble. The most satisfactory tests were obtained by the addition of serum to the media. Positive cases varied very much in the length of time necessary for producing acid—viz., one to six days. Growth at 23° was delayed in some cases till the fifth day.

Owing to the absence of a systematic agglutinating test the percentage of positives was doubtless too high.

No contacts were known to catch the disease. Duration of the organism in a contact was usually less than 17 days, but one lasted for 11 weeks. The duration appeared to be independent of treatment. Out of 14 swabs taken at the commencement of an attack 3 were found positive only.

The following table shows the number of positive contacts as they occurred in each 100 swabbed, and the dates of same:

	+	-
First 100 November-March	10	90
Second 100 March-April	8	92
Third 100 April-May	8	92
Fourth 100 May	15	85
Last 103 June-August	6	98
	46	457

**MEDICO PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.**—The next general meeting of the association will be held on Thursday, Feb. 15th, at 3 P.M., at 11, Chandos-street, Cavendish-square, London, W., when a paper will be read, entitled "Dreams and their Interpretation, with reference to Freudism," by Dr. Robert Armstrong-Jones.

**LITERARY INTELLIGENCE.**—For the use of medical men engaged in war work, Messrs. J. and A. Churchill have published the following during the week: A sixteenth edition of "Minor Surgery and Bandaging," by Mr. H. Morriston Davies, and a second edition of "Sanitation in War," by Major P. S. Lelean, R.A.M.C. New illustrations have been inserted in this volume and the whole of the text has been revised.

## ON THE TREATMENT OF SCABIES AND SOME OTHER COMMON SKIN AFFECTIONS IN SOLDIERS. |

BY H. G. ADAMSON, M.D. LOND., F.R.C.P. LOND., PHYSICIAN FOR DISEASES OF THE SKIN, ST. BARTHOLOMEW'S HOSPITAL; HONORARY CONSULTANT FOR SKIN DISEASES IN MILITARY HOSPITALS IN LONDON.

MEDICAL men in charge of patients in military hospitals, convalescent homes, and camps are often called upon to diagnose and treat certain diseases of the skin. Contrary to what one might expect as a result of the conditions under which a soldier lives on active service, the list of these complaints is not a long one. Eczema, in the production of which local irritants are known to be a prominent factor, is by no means common among soldiers, in spite of infrequent baths and change of clothing. On the contrary, many men who in civil life have been victims of eczema, have lost that complaint while serving in the Army, perhaps as the result of a better state of general health. Neither does one see, as again one might expect to see among those who have been at the front, lichen planus, an affection which in civil life is often caused by stress or nervous worry. The really frequent skin affections of soldiers are comprised among the more common contagious skin diseases. Pediculosis, scabies, impetigo contagiosa are probably the most prevalent, then certain forms of ringworm. If we add to these the eruptions of secondary syphilis and psoriasis vulgaris, these half-dozen affections are those with which a military doctor is most likely to meet.

Pediculosis is mainly a complaint of the trenches, and, as "the louse problem of the western front," its management has been fully discussed in the medical journals. Syphilis is a disease which at once passes out of the hands of the local medical officer to be treated in special hospitals for venereal diseases.

Scabies, impetigo contagiosa, and to a less extent ringworm, though in a sense trivial complaints, are nevertheless responsible for the temporary invaliding of hundreds, perhaps thousands, of otherwise able-bodied men. Measures for the treatment of these diseases are therefore worthy of attention. Psoriasis also invalids many otherwise healthy men and sends them to hospital either because of the extent and consequent discomfort of the eruptions, or because the eruption is looked upon with suspicion by the man's companions.

### Scabies.

It is a very good rule, when a soldier (as, indeed, a civilian), of whatever rank, complains of itching, to think first of scabies, and to exclude that disease before giving consideration to any other. Itching at night is particularly suggestive of scabies.

One looks between the fingers and about the wrists for "burrows," and on the buttocks, and particularly on the penis, for red raised ridges, the result of burrows which have become inflamed by scratching or infection.

On the fingers and wrists the burrow is seen as a narrow wavy line, generally black from included dirt, and  $\frac{1}{8}$  inch to  $\frac{1}{4}$  inch long. Sometimes there is near, but not actually at one end of, the burrow a clear pinhead-sized vesicle—the pearly vesicle—over the roof of which the burrow passes. When examined with a lens the acarus can be seen at one extremity of the burrow as a whitish speck like a minute smooth flat pebble imbedded in the skin. When seen it can be easily removed by touching it with the point of a darning needle and examined under the microscope in a little liquor potassæ, and the diagnosis is certain once for all. This is the only sure way of finding the acarus; to grope for it blindly in the burrow or the pearly vesicle is useless.

As has been stated, burrows sometimes become inflamed, and an "inflamed burrow" forms a red, raised, ridge-like papule, on the crest of which the burrow can be seen on close inspection. The elongated shape of the papule is alone suggestive of scabies, and an "inflamed burrow" on the penis is a sure diagnostic sign of scabies in a man.

But scabies is often complicated by (a) impetigo contagiosa or by (b) eczema, and in either case it may be then less easy to find a typical burrow and an acarus.

When complicated by impetigo, the hands and feet particularly are the seat of vesicles and blisters with clear or turbid contents, together with crusts, erosions, and inflamed burrows; and there may be crusted infiltrated nodules (ecthyma) on the buttocks, and often crusts and erosions on other parts, sometimes here and there a small furuncle.

When eczema complicates scabies there are red, rough, eczematoid areas, sometimes dry and sometimes weeping, on the hands, arms, thighs, and trunk, masking often the burrows of the original complaint. In many instances the eczema is caused by too prolonged use of sulphur applications, but it may also result from constant scratching in scabies of long standing.

In respect to the contagion of scabies, it should be remembered that it is usually in men a venereal disease, but that it may also be conveyed to others by means of things which are handled, such as books, playing-cards, dominoes, and utensils of all sorts.

*Treatment of scabies.*—It was said by Hebra 50 years ago that "there is, perhaps, scarcely any other curable disease for which so many and various remedies have been proposed as for scabies. Those enumerated in medical works amount to hundreds." Of the treatments which have survived there is none, perhaps, so universally employed to-day as that recommended by Hebra of baths, soap, and sulphur ointment. The method of "sulphur fumigations," recently recommended by Major John Bruce and Captain Stanley Hodgson, dates back from the seventeenth century, and it is worthy of remark that Hebra said of this method after a trial in the General Hospital of Vienna, that "the results obtained were not such as to lead to the further adoption of the method, for it was found to set up artificial eczematous eruptions, which so greatly prolonged the treatment that its average duration exceeded four weeks."

The all-important points in dealing with cases of scabies are (1) to make sure of the diagnosis, if possible by finding an acarus; (2) to then carry out a very thorough treatment for a strictly limited period. Doubt in diagnosis often leads to ineffectual treatment; treatment ineffectual but too long-continued leads to eczema or sulphur dermatitis and still further confuses the diagnosis.

The simplest and most efficacious treatment is as follows:—

- (1) R Saponis mollis ... ... 24 oz. (700 gm.)
- (2) R Ung. sulphuris ... ... 24 oz. (700 gm.)

S. The soap and ointment for three applications.

(1) A hot bath of half-an-hour's duration is taken on three consecutive days. During the bath the body and limbs, especially the hands and wrists and buttocks, are scrubbed with soft soap by a flesh brush.

(2) After each bath the patient himself rubs in the ointment and puts on an old sleeping suit, gloves, and socks and goes to bed, where he remains until it is time for the bath on the next day.

The baths and inunctions must on no account be continued beyond the three days. The patient gets up and dresses after the three days and usually requires no further treatment, but is kept under observation for another three days. If, as sometimes happens, some itching continues he is given the following lotion to mop on night and morning.

- R Liq. picis carbonis... ... 1 dr. (4 c.c.)
- Aq. ... ... ... ... 20 oz. (600 c.c.)

If the treatment has been thoroughly carried out the patient is cured and free from infection after the three baths and inunctions. If a case is not cured in this way, it is probably not scabies, but either a papular urticaria or chronic eczema. For the former affection a lotion of ordinary vinegar is often efficacious. For the eczema a zinc ointment as follows should be freely applied and all baths forbidden.

- R Zinci oxid... ... ... 1 oz. (30 gm.)
- Pulv. amyli ... ... 1 oz. (30 gm.)
- Vaseline. ... ... ad 10 oz. (300 gm.)

By this method of treating scabies, with one bath and a good supply of hot water, from 12 to 16 men can have treatment each day, or a complete cure for 24 to 32 men per week, and so on, in proportion to the number of baths available. Clothes may be disinfected, but in practice this is found to be unnecessary. Brushing and airing of outside clothes and washing of underclothes suffice.

#### *Impetigo Contagiosa.*

It has been already remarked that impetigo may complicate scabies and that it then attacks particularly the hands, buttocks, and thighs. But it often occurs apart from scabies as single cases or in small epidemics.

Its usual situation is then the face, beard region and scalp, and the fingers. It is of common occurrence as a result of a visit to the barber or from using a public towel. It usually begins on the beard region as scattered isolated crusts, which quickly spread on to other parts of the face, about the ears, and sometimes on to the neck and scalp. It is often mistaken for sycosis or for eczema, but it is easily

recognised by the appearance of "stuck on" amber-coloured crusts from the size of a split pea to that of a shilling. Each of these crusts represents the dried serum of a blister, but the drying takes place so quickly that the original blister is seldom seen, though on removing a crust with forceps there is revealed a raw weeping surface, which is the base of the blister. Frequently there is a phlyctenular whitlow on a finger or thumb around the root of the nail, and there may be crusted patches on the hands or forearms.

This eruption is often wrongly supposed to be of staphylococcal origin, but it is really due to a streptococcal infection. If untreated the infection spreads rapidly, especially in hot climates or warm weather. If effectively treated the eruption may be cured in a few days or a week, but if not rightly dealt with, sooner or later a secondary staphylococcal infection supervenes. The staphylococcus invades the hair follicles of the beard, eyebrows, eyelashes, and scalp, and a deep-seated, intractable, sometimes incurable, pustular dermatitis results. On the beard region this staphylococcal infection is known as *sycosis*, and on the eyelids as blepharitis, but the exactly similar condition on the scalp and eyebrows has no definite name, and is often wrongly called pustular eczema. It might be called *sycosis capitis*, or chronic impetigo.

*Treatment of impetigo contagiosa.*—The essential part of the treatment of impetigo is the complete removal of every scrap of crust in order that any antiseptic application may reach the site of the invading micro-organism.

The patient should be made to mop off the crusts with a wad of wool and hot water, and to continue to mop for half an hour or until every crust is removed. A lotion of 1 in 6000 hydrarg. perchlor. is then daubed on for a few minutes and a diluted white precipitate ointment applied (hydrarg. ammon. chlor. 10 gr. (0.6 gm.), vaseline 1 oz. (30 gm.)). The bathing and application of ointment is repeated several times daily and continued until no fresh crusts are formed. In this way the most extensive eruptions can be cured in a few days. Without the thorough removal of crusts the ointment fails to reach all the infected parts and the eruption continues. With wrong or inefficient treatment a secondary staphylococcal infection supervenes and an intractable chronic impetigo or "sycosis" results. If dealt with early a "sycosis" may often be quickly cured by staphylococcal vaccines, but where long established vaccines fail, and other treatments, including X rays, may be tried in vain until the man is finally discharged from the Army as incurable.

#### *Ringworm.*

Ringworm is a third contagious skin complaint which may incapacitate soldiers, though it is less generally prevalent than either scabies or impetigo.

It may occur on the beard region or on the forearms in the form of large disc-like inflammatory plaques with pustulating points as the result of infection from horses, and epidemics of "horse-ringworm" of this sort were at one time prevalent in certain cavalry camps, but have apparently now ceased to occur.

More general forms are ringworm of the groin (*tinea cruris* or Diphilic itch) and eczematoid ringworm of the extremities. Groin ringworm is perhaps more often met with among officers, and ringworm of the toes and feet particularly in hot climates or during warm weather. Ringworm of the groin and the interdigital ringworm may sometimes be associated in the same patient. Ringworm of the toes and feet most calls for attention because it is less generally known and recognised as such. In its mildest form it causes red, dry, or excoriated surfaces between the toes due to peeling off of the horny layers of the epidermis. The red surfaces are sharply margined from the normal skin by an overhanging fringe of epidermis and they generally extend on to the sole of the foot. In cold weather it often remains in this condition and causes comparatively little discomfort. In hot weather, and in tropical climates especially, the eruption may spread rapidly and extend over the foot and even up the leg to the knee in the form of blisters and excoriations, sometimes with oedema of the leg. Many such cases were seen invalided from Gallipoli.

One of two measures may be adopted in treating any of these forms of ringworm.

(1) The application of an ointment which we owe to Dr. Arthur Whitfield—viz.:

- R Acid. benzidi ... ... ... 15 gr. (1 gm.)
- Acid. salicylic ... ... ... 15 gr. (1 gm.)
- Oi. coca-nucls... ... ... 3 dr. (12 gm.)
- Vaseline. ... ... ... ad 1 oz. (30 gm.)

In cases where there is vesication the inunction should be preceded by fomentation with hot water. Many cases quickly clear up with this treatment, but sometimes part of the eruption in the groin, or between the toes,

or on the soles remains obstinate, and for these cases a useful treatment is:—

(2) First thoroughly mop the affected parts with *tinctura iodii*; then rub on *argent. nitratii* 10 gr. (0·6 gm.), *spiritus etheris nitrosi* 1 oz. (30 gm.). Repeat this treatment if necessary, and apply the benzoic acid ointment between whishes.

For the treatment of *psoriasis* in soldiers it is but waste of time to try internal remedies. They are generally disappointing, and, in any case, show no results for weeks. It is better to at once apply local remedies.

The following ointment is often successful in removing the eruption:—

B. Hydrg. ammon. chlor. ....	1 dr. (4 gm.)
Liq. picis carbonis....	... ... ... $\frac{1}{2}$ oz. (15 c.c.)
Ung. paraffin. B.P. ....	... ... ... 6 oz. (180 gm.)

S. The ointment to be well rubbed in twice daily with a piece of flannel. This ointment, which is made with a stiff basis—ung. paraffin—is usually more effectual than when made with simple vaseline. If this ointment fails, ung. chrysarobini B.P. should be employed, with the usual precautions of avoiding the face, hands, and scalp, and relaxing the treatment if chrysarobin erythema appears at any part. The patient should be kept in bed when chrysarobin ointment is used.

The treatment of psoriasis will be usually slow, but for most of these complaints it may be said that with prompt and efficient treatment the period of hospitalisation will be reduced to a week or so, while inefficient treatment may prolong that period to many weeks or months, or lead even to eventual discharge of men from the Army with the complaint still uncured. This, then, is the excuse, if such be needed, for venturing to discuss these somewhat banal subjects.

Devonshire-place, W.

## BLINDED SAILORS AND SOLDIERS : REMARKS ON THE TRAINING AT ST. DUNSTAN'S.

By ARNOLD LAWSON, F.R.C.S. ENG.,

OPHTHALMIC SURGEON AND LECTURER ON OPHTHALMIC SURGERY,  
MIDDLESEX HOSPITAL; OPHTHALMIC SURGEON TO  
ST. DUNSTAN'S HOSTEL.

THE fact that the great war rapidly developed largely into a trench warfare has caused head injuries to figure very prominently in the casualty lists. One of the after-consequences of many of these head injuries is partial or complete loss of sight, and as a result the war had not been many months in progress before a number of discharged blinded soldiers were thrown on to the nation's charity. As in many other matters the nation was not prepared for this state of things, and St. Dunstan's was the first, as it has now grown to be the final and complete, answer to the urgent cry for help from the sufferers. Everybody now knows that St. Dunstan's was initiated, put into being, and carried on to what it now is by the self-devotion and genius for organisation of Sir Arthur Pearson, who has given the whole of his marvellous energies, and incidentally has largely sacrificed his health, to perfecting a scheme for the training of blinded soldiers and sailors.

St. Dunstan's started just a short 22 months ago in a large house in the Bayswater-road. Thence in March, 1915, it moved to its present quarters in Regent's Park, where on the 15 acres of available land it now lodges about 180 men, and here the greater part of the training is carried out. But St. Dunstan's stands for much more than this. It now includes the Regent's Park College, recently made over by the generosity of the Baptist College Committee, with its possible accommodation for about 200 more men. In addition two large houses in Portland-place serve as accommodation for blinded officers, and two houses in Paddington are also being used to lodge some of the men for whom there is no available space at St. Dunstan's for the moment. Further, four convalescent homes (two at Brighton, one at Blackheath, and one at Torquay), with accommodation between them for 112 patients, serve a most useful purpose in providing the men with week-end and longer trips to rebuild their health. These homes have proved a very great boon, as numbers of the men suffer a great deal from headache and malaise long after their wounds have healed.

Moreover, the work at St. Dunstan's does not end with the training of the men, but purposes to settle them after training—i.e., to provide homes for them, to set them up in business, and to supervise them after settlement. Thus the

"settlement" and "after-care" departments of St. Dunstan's have grown into a great and responsible undertaking, and the work is of necessity very rapidly increasing. It is a work which requires great organisation, and already has advanced to the stage of portioning the United Kingdom into districts, each with its own supervising secretary and branch establishment.

At the present moment there are 388 blinded soldiers and sailors on the books at St. Dunstan's. Of these, 280 are actually at St. Dunstan's or its attendant convalescent homes, whilst 108 are in hospital either waiting admission or sent into hospital as requiring medical treatment in some form.

For the purposes of admission a man is considered fit whose sight is so injured that he is incapable of leading an independent existence. There are many, therefore, who can distinguish light, though a large majority are absolutely blind. A difficulty has existed in regard to a certain number of cases which are partly or wholly functional—cases of bad "shell shock," as it is loosely called, for example. To sift and apportion the functional and organic elements in many of these cases is a matter of great difficulty, and to train a purely functional blindness as if it were an organic blindness may be the worst possible treatment. However, ways and means have generally been found to deal with these cases, and the convalescent homes have proved very valuable adjuncts in helping to the right decision.

The great factor in the success which has attended St. Dunstan's is the youth of most of the patients. It is far better to go blind young than to lose sight after middle age. The buoyancy of youth, its power of repair, mental as well as physical, and its inherent faculty of living in and for the present without undue inquiry into a remote future, make it possible for blinded youth quickly to pick up the severed threads and start life again. Such elasticity is out of the reach of the aged, and consequently the training of the youthful blind is far easier and far more gratifying in its results than training applied to the old.

At St. Dunstan's the men are all taught to shun self-pity. Commiseration is avoided, and from the start the man is encouraged to accept his lot as an inconvenience and not as a disability. He has got to make the best of it, and the best is a very good one if it is learnt aright. A visit to St. Dunstan's at any time will speedily assure the stranger that this spirit is quickly and cheerfully accepted, for there is no cheerier place in London.

Another and equally important point in the training is the teaching of independence. The blind man instinctively becomes increasingly dependent on others if left to himself, and the greatest pains are taken at St. Dunstan's to show the men how to shift as far as possible for themselves. Various simple devices are adopted and after a very short stay the man will be found cheerily going about his own business without a thought of seeking outside help. A more subtle difficulty is the natural "suspicion" of a blind man. Everybody instinctively gauges the value of a word by watching the speaker, and the loss of this faculty of watching weighs very heavily on many blinded people. The feeling of distrust soon wears off at St. Dunstan's in the life of good fellowship amongst others similarly handicapped, aided by the inspiration afforded by the experiences of those who have lived at the hostel for some time.

The actual training of the men occupies a work day of four hours, two hours being given up daily to learning Braille and typewriting, and two hours to the learning of handicrafts or trade. The hours are not long, but the blind man has to visualise everything mentally, and has consequently to concentrate intensely upon all his work. Thus the blind man gets tired much more quickly than the sighted man even when "fit," and very many at St. Dunstan's are anything but "fit." Typing is quickly learnt, and if an "efficiency" test is passed the man on leaving the hostel is presented with a Remington typewriter. Braille presents many difficulties to the older and to the more uneducated men, as also to a good many of those who have had severe head injuries. I am in hopes that a simplified Braille may be devised to meet this need. For a selected few massage, poultry farming, and telephoning form very suitable occupations; but these are not for the majority, who are set to learn simpler things, such as mat-making, basket- and hamper-making, carpentering, or cobbling. Two of these rougher trades are usually learnt by each man. The average time occupied in

the training is from six to eight months, but illness often causes an extension of the period needed. In any case the man is kept until he is thoroughly well qualified to start life again on his own account. Up to the present time 150 men have been fully trained and settled.

To keep the men in good physical condition much care is taken. Early morning Swedish exercises in the open air in the summer and indoors in the winter, and rowing on the water of Regent's Park form very good aids in this direction, whilst a number of voluntary workers come to give the men good walking exercise each day.

The social side of the hostel is abundantly looked after. There is a very large social hall where some form of entertainment takes place nearly every evening, and, further there has recently been added a very large "quiet room," fitted with easy chairs where the men can resort for a quiet smoke and rest. A chapel, too, has just been completed, and its services will undoubtedly prove of great comfort to the men.

The maintenance of general order and discipline sounds a formidable matter, but on the whole the difficulty has been less than anticipated. A great deal is done by appeals to the honour and good sense of the men themselves, the vast majority of whom realise the essential necessity of order and give offenders against the rules a very poor time. At the same time, it is very easy for one or two bad characters to upset thoroughly the whole place, and it has been found necessary in a few instances, and after due warnings, to get rid of the offender.

Harley-street, W.

## Clinical Notes: MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### A CASE OF INTESTINAL OBSTRUCTION BY THROMBOSIS OF MESENTERIC VEINS; OPERATION; RECOVERY.

By S. C. GHOSE, M.R.C.S., L.R.C.P. LOND.,  
HOUSE SURGEON, ROYAL ALBERT HOSPITAL, DEVONPORT.

THE following case may be deemed of sufficient interest to merit publication.

The patient, aged 54, a labourer's wife, habitually constipated, was suddenly seized with severe abdominal pain, referred to the right of the umbilicus, a pain which "doubled her up." The condition passed off, only to return soon after, followed by vomiting and arrest of the passage of flatus and faeces, which state continued till she was admitted into the hospital after three days. During that time she was treated outside for intestinal obstruction by Dr. T. N. Leah, as she refused early surgical treatment.

On admission the temperature was 97° F., the pulse-rate 80, and the respirations 26, and on the following morning they were 98.4° F., 116, and 28 respectively. The abdomen was slightly distended with gas, and vomiting was very frequent and faecal-smelling. There was no visible peristalsis. Nothing was found per rectum or per vaginam. A soap enema, followed in three-quarters of an hour by a turpentine enema, was administered without result. The patient was prepared for operation and the stomach was washed out.

On the fourth day after the onset of illness a laparotomy was performed by Dr. Leah. About 12 inches of distended small gut with attached mesentery was found to be of a deep chocolate colour, just above a constriction ring, beyond which the gut was perfectly healthy. The attached mesentery was soft and oedematous and gave way on manipulation with some haemorrhage. No band, adhesion, tumour, or ulcer was found to account for the constriction ring. No peristalsis was visible in the affected area. Some peritonitis was present. The attached mesenteric veins were found to be thrombosed. The affected area of the gut was re-ected, and end-to-end anastomosis was established by simple sutures, closing the abdominal wound in four layers, the whole operation taking about an hour.

The patient ten days after the operation was getting on well, although she had been troubled with vomiting, meteorism, and great thirst during the early part of the after-treatment. She left the hospital perfectly cured five weeks after the operation, and is doing light work at home.

I am indebted to Dr. Leah, surgeon to the hospital, for permission to publish the case.

### A CASE OF APPARENT DISAPPEARANCE OF CARCINOMA OF CERVIX.

By EDWARD C. B. IBOTSON, M.D. LOND., &c.,  
TEMPORARY LIEUTENANT, R.A.M.C.

A PAPER read before the Section of Therapeutics and Pharmacology of the Royal Society of Medicine in 1909 by Mr. Wippell Gadd and another author stated that the violet leaf contains a glucoside (viola quercitrin), which is an anti-septic and has the property of easing the pain and lessening the discharge of uterine cancer and also of keeping the urine sweet for a long period after it had been passed, but they did not find that it had any curative effect. The fact that in the following case the nodules disappeared from the scar on the thorax is very remarkable. How far it was due to the violet-leaf infusion combined with other measures and how far it might be considered a temporary or permanent disappearance of carcinoma is difficult to say, but the case seems one worthy of recording.

The patient, a married woman aged 45, had her left breast amputated for cancer in 1914 at Liverpool, and has been under my observation ever since. In July, 1916, symptoms of uterine cancer appeared, and also nodules developed in the operation scar. Offensive vaginal discharge tinged with blood, obstinate constipation and vomiting, painful and difficult micturition, and pain in the left sciatic nerve area. Another medical man, Mr. W. R. Williams, Machynlleth, saw her with me in August and agreed that there was extensive ulceration of the cervix, carcinomatous in character, and that the uterus was fixed in the pelvis and appeared bulky. We agreed that she was too weak to stand another operation so extensive as hysterectomy, and that palliative treatment combined with enemas and vaginal douches was all that could be done. I also suggested vaginal injections of infusion of wild violet leaves, and that the patient should also take a little infusion of the violet leaves internally. This has been persevered with, and she has steadily improved. The nodules in the scar disappeared in September and I can find nothing abnormal in the cervix, and the uterus is now freely movable. Also the constipation and vomiting have quite ceased. She has still pain in the left sciatic nerve area, and is exceedingly thin, as indeed she always has been. But she is taking plenty of nourishment and the pain in the nerve is not so great as to require morphine. She sits up in a chair daily.

Corris, North Wales.

### A CASE OF SARCOMA OF FOURTH VENTRICLE.

By H. M. GALT, B.Sc., M.B. GLASG., D.P.H., F.C.S.,  
PATHOLOGIST, ROYAL SUSSEX COUNTY HOSPITAL.

THE following case presented unusual features, clinical and pathological, and is reported in the hope that the notes may be found useful by others who have to deal with similarly misleading clinical conditions.

The patient, a girl aged 14, was admitted to the Royal Sussex County Hospital, under Lieutenant-Colonel E. Hobhouse, about the middle of July, 1916, with a history of having had "meningitis" some months previously. Apparent complete recovery from the "meningitis" occurred, but since that time the patient had occasional periods lasting a few days, during which she appeared to be in a state of coma. In the intervals she appeared to be practically normal, and at no time was there headache, vomiting, paralysis, or any physical sign suggesting the presence of tumour. This naturally led to the suggestion that possibly the condition was hysterical in origin. Death occurred on August 8th, during one of the spells of coma, and the question of cerebral tumour was raised definitely, although as a possibility this had not been lost sight of all along.

*Post-mortem.*—A soft tumour about the size of a large walnut was found, apparently originating in the valve of Vieussens and separating rather widely the two lateral halves of the cerebellum. There was no definite pressure on the floor of the fourth ventricle, and the lateral ventricles of the brain were not distended. The tumour showed several comparatively large recent areas of haemorrhage within it. In structure it was, histologically, a small round-cell sarcoma. There was no visible stroma, and no gliomatous elements. The cerebral and cerebellar tissues were normal in structure and all the other organs of the body were normal.

The absence of practically all symptoms except recurrent coma made the case a very difficult one to diagnose. On the other hand, this coma was rightly looked upon as a grave symptom, and the patient was kept in hospital in spite of the intercurrent, apparently normal, spells.

Brighton.

## Medical Societies.

### ROYAL SOCIETY OF MEDICINE.

#### SECTION OF ELECTRO-THERAPEUTICS.

##### *History of the Electro-Therapeutic Department of St. Bartholomew's Hospital.*

THE monthly meeting of this section was held at St. Bartholomew's Hospital on Jan. 19th, and took the form of a clinical evening to enable members to inspect the electro-therapeutic department of the institution. Dr. G. HARRISON ORTON, the President, occupied the chair.

Dr. E. P. CUMBERBATCH, who has charge of the electrical department, read a paper on the history of the department and its work. This did not include the X ray section, which is under the superintendence of Dr. Hugh Walham. The department was founded in 1882. Prior to that date ordinary electrical treatment and testing by faradism and galvanism were carried out in the wards by the house surgeons and dressers. The equipment at the commencement was a very modest one—waiting-room, testing-room, a room for electrolysis, and a bath-room containing a single bath, which for years remained the only electric bath in London. There were three batteries, each containing 50 cells. During the first year 55 in-patients were treated, the cases including paralysis, hysteria, ankylosis of joints, sciatica, epithelioma, and caruncle—the latter for destruction by electrolysis. In the years 1883-5 269 inpatients were treated and 876 out-patients. In 1891 Dr. Stephenson died and was succeeded by Dr. H. Lewis Jones. In 1896 the first skiagram was taken in the hospital, and since then the amount of X ray work had increased yearly. Dr. Lewis Jones's work in the department was very devoted and thorough until his retirement in 1912; indeed, since 1891 the history of medical electricity was closely interwoven with his writing and teachings, and the position occupied by the specialty to-day was largely due to him. Previously there was much obscurity among physicians as to the scope and limitations of electricity in medicine. In 1916 497 new patients were admitted, of whom 284 were cases of disease or injury of the nervous system, mainly peripheral, and for testing. For paralysis the sinusoidal current was generally used, the paralysed parts being immersed in electrified water-baths. This had been in use for many years and produced good results. For 64 cases of neuritis, 186 operations under anaesthesia had been performed. For cavernous neuritis he (Dr. Cumberbatch) found electrolysis gave the best results, the skin undergoing the least damage thereby. CO<sub>2</sub> snow, diathermy, or the cautery, if effective, destroyed also much underlying tissue. CO<sub>2</sub> snow reserved for capillary naevi when situated on the trunk or limbs over soft parts. There were also treated in the same time 49 cases of disease of the skin, including 11 of rodent ulcer. Joint cases by occasional attendance were able to secure a decrease of pain and increased movement. There had been but few cases treated in the department of alimentary, vascular, and genito-urinary diseases. Gynaecological cases were not received there. Most of the cases were sent by officers of the hospital and by private practitioners. He was fortunate in the fact that most of the cases he received were suitable ones for electrical treatment; some were only sent because many other treatments had been tried without avail, and by those medical men who appeared to regard the electrical department as a refuge for the destitute. Many cases which were eminently suitable for such treatment, however, did not reach that specialty, and he felt that electricity was not yet occupying the position in medicine to which it was entitled. The reasons for this were, he submitted, three in number: (1) Lack of knowledge on medical electricity by the bulk of practitioners; (2) prevalence of incorrect knowledge on the subject; and (3) the carrying out of electrical treatment by unqualified and unsuitable people. In regard to the first of these, medical students did not attend the electrical department, because they were interested entirely in passing their examinations, and in the M.B. examinations no questions were asked on this subject. Under the second heading, the bulk of practitioners continued in the belief that electricity was for cases which were incurable by other means. Many

institutions existed for turning out, armed with a certificate, men intended to carry on unqualified practice, grossly ill-fitted though they were for practising medical electricity. Much improvement in regard to medical students could not reasonably be expected so long as the examinations did not include questions on the specialty. He had not had one student in the department while it had been under his charge. There should be a wider knowledge as to the kinds of cases suitable for electrical treatment and to this end he advocated the exhibition of lists of such conditions in the waiting-rooms. He also recommended that the X ray work should be in a separate department from that for electro-therapeutics, a method now in operation at the 1st London General Hospital, where only two forms of current—the sinusoidal and the direct—were allowed. At the Miller Hospital, Greenwich, the same separation of departments was in operation.

Dr. R. ARMSTRONG-JONES, who entered the hospital 40 years ago, when Dr. Stephenson was house physician, spoke of the benefit which subjects of dementia precoox derived from an electrical bath for 20 minutes twice a week at Chelbury Asylum. This experience was embodied in Dr. Lewis Jones's well-known book on medical electricity.

Dr. W. J. TURRELL referred to a Dr. Stephenson who practised 100 years before the Dr. Stephenson to whom Dr. Cumberbatch adverted, and who in his M.D. Edinburgh thesis described the static breeze. He confirmed the remarks as to the great help given by the late Dr. Lewis Jones to a fuller recognition of the claims of medical electricity by the profession. One of the most potent steps towards this recognition was taken when medical men themselves were treated by this means.

Dr. JAMES METCALFE Dr. AGNES SAVILL, and Dr. HOWARD HUMPHRIS also discussed the paper, the general expression being in favour of not regarding irregular practitioners as competitors, but of so maintaining the specialty at a high level, while striving to make new advances, that the public would come to see it was in their own best interests to consult recognised authorities.

Dr. CUMBERBATCH replied.

**WEST LONDON MEDICO-CHIRURGICAL SOCIETY.**—A pathological meeting of this society was held on Feb. 2nd, Dr. A. Saunders, the President, being in the chair.—A paper was read by Dr. A. K. Gordon on the Clinical Significance of Laboratory Tests for Syphilis.—Dr. J. A. Shaw-Mackenzie showed specimens demonstrating the Action of Copper Salts on Protozoa.—Specimens were also shown by Mr. Aslett Baldwin, Dr. Bamford, and Dr. H. H. Sanguineti, and skiagrams were shown by Dr. Reginald Morton.

**LONDON DERMATOLOGICAL SOCIETY.**—A meeting of this society was held on Jan. 16th, Dr. W. Knowsley Sibley, the President, being in the chair. The following clinical cases were shown:—Captain W. Griffith, R.A.M.C., exhibited a case of Kaposi's Disease. Captain P. Carney, R.A.M.C., gave the following description of the case: A Canadian soldier, aged 20 years, who had worked in the open all his life, either as a labourer or a carpenter, developed a general pigmented condition of the skin of the face, accompanied by warty growths and marked telangiectasis. Some of the lesions had been removed by excision, others were treated with radium. After this treatment the lesions became inflamed and very painful, but eventually dried up and completely disappeared. He described the history of the disease as being first a macule, then a papule followed by a warty growth, accompanied with ulceration. There was no family history.—Dr. Morgan Dockrell brought forward a case of Xeroderma Pigmentosum, as described by Kaposi.—In contrast to the above cases Dr. J. L. Bunch brought forward one of von Recklinghausen's disease in a female, which was of 15 years' duration, the tumours, which varied in size, were universal in distribution and slightly pigmented; also a case of Strychnine Rash in a man aged 51, and a case of Epithelioma affecting the dorsum of the right hand in a man aged 66.—Captain Griffith also exhibited a case which he described as syphilis and psoriasis.—Mr. C. H. Mills said that he had an opportunity of seeing several cases of psoriasis in which syphilis had come out on the top; the blood in these cases had been tested and a positive Wassermann reaction obtained in what appeared to be acute cases of psoriasis.—Lieutenant-Colonel L. W. Harrison, R.A.M.C., said that the Wassermann reaction in these cases

was an extremely important point, and he described the present tests that were being used in the various laboratories as being too light in value. In these conditions, he said, it was extremely likely to get positive Wassermann reactions in such cases as Mr. Mills had described; his own modification of the test, being less delicate, had been designed to escape these errors, as a strong reaction was demanded and not simply a positive manifestation.

## Reviews and Notices of Books.

### *Encyclopædia Medica.*

Second edition, under the General Editorship of J. W. BALLANTYNE, M.D., C.M. Vol. IV. Ear to Filariasis. London and Edinburgh: W. Green and Son, Limited, 1916. Pp. 685. Price 20s. net.

An encyclopædia is a hard nut for a reviewer to crack, but the fourth volume of this great work gives us the opportunity of reviewing a series of articles on kindred subjects. The articles on the ear occupy a quarter of the volume and furnish a good instance of the associated strength and weakness of the encyclopædic method. The inevitable inequality of performance is balanced against the excellence of some of the articles. The single editorship is not enough to pull together the loosely strung contributions into a whole. The publisher's part is excellent, illustrations are good, plentiful, and modern, although the prehistoric old woodcut on p. 4 is out of place.

Of the several articles we welcome especially those on otosclerosis and on the labyrinth and eighth nerve. Both are thoroughly up to date, and that on otosclerosis may be said to be almost in advance of its text-book time. The labyrinth and eighth nerve are treated in genuinely encyclopædic style, and a most satisfactory article results. The weak spot lies in the articles on inflammatory diseases of the ear. Here there is too much overlapping between the writers of the "acute" and "chronic" articles, while the treatment of chronic middle-ear suppuration and its sequelæ is almost startlingly inadequate. The whole article only occupies 35 pages. The radical mastoid operation takes three-quarters of a page; the only two flaps for the plastic operation on the meatus mentioned are those of Panse and Milligan, neither, we believe, in general use, while no mention is made of Ballance's flap, probably the most widely used and generally useful of all, apart from its historic claims. In the portion of the article devoted to meningitis we find no mention of Babinski's sign, no mention of jerks, knee and other, nothing said of neck-stiffness or of the abdominal reflex. Kernig's sign is spoken of as if it were a matter the writer had heard of but had not experimented with. This part of the article is punctuated with loose expressions, such as "lumbar fluid," "antrectomy," "pia arachnoid cavity," and later, under lateral sinus thrombosis, the sentence, "the occurrence of a rigor, or series of rigors, followed by an attack of shivering," leaves the reader in doubt as to what constitutes a rigor in the mind of the author.

The article on chronic catarrh of the middle ear is thoroughly sound and sensible, and if the writer has nothing very fresh to say, at all events he gives no encouragement to overmuch tinkering. Attention might, however, have been more firmly directed to the treatment of the antecedent causes which are quite justly enumerated. The introductory "examination of the ear" is thorough, clear, and modern, and is one of the best articles of the series.

### *Les Appareils Plâtrés.*

By JACQUES CALVÉ and MARCEL GALLAND. With 109 illustrations. Paris: Baillière et Fils. 1917. Pp. 88. Price fr. 2.50.

THIS little volume is the first of a series of French practical handbooks to be produced under the editorship of Dr. Calvé and Dr. Lamy. As the authors state in their preface, their aim is to give practical instruction, and in this they have succeeded admirably. Plaster-of-Paris, while of universal use in this country, is not employed with us to the same extent as it is in France, and few English practitioners are aware of the skill which French surgeons have acquired in its uses.

The volume is divided into three parts: (1) The making of the plaster apparatus; (2) the orthopaedic principles requisite for immobilisation; (3) special technique in the application of plaster to various conditions. In the first part the manufacture of the plaster apparatus is described lucidly and with special attention to practical requirements. Reversing, in applying a plaster bandage, is condemned, and in its place Ducroquet's pleating manœuvre, which has incontestable advantages, is described in detail. Great stress is rightly laid on the importance of correct and accurate moulding, and full directions to secure adequate moulding are detailed. Attention is drawn to the accidents which may arise in the application of plaster, and their appropriate remedies are indicated. The disadvantages of plaster are briefly discussed and dismissed. There is little to criticise but much which may be commended. The directions given are terse, clear, and essentially practical. Part 2 is devoted to the orthopaedic principles involved in immobilisation by plaster apparatus. Brief and to the point, this section well repays perusal, and its study will prevent many errors commonly seen and easily avoided. The third portion is directed to special technique. The clearest instructions are given with restraint and brevity. Naturally considerable attention is directed to the application of plaster-of-Paris in tuberculous disease of the bones and joints. The authors still favour the use of the "Minerva" in cervical caries. While this appliance is certainly efficient, it is uncomfortable and not altogether devoid of danger. Alternatively preference might be given to a high plaster jacket with a frontal band which would render unnecessary immobilisation of the chin and leave the throat free. The use of the Minerva is not to be commended to the inexperienced. This, the most difficult of all plasters to apply successfully, not unnaturally attracts the ambition of the tyro, and failure in its application may result in his discouragement and be a source of danger to the patient. It should be reserved for the expert only. A short article is devoted to the Abbott jacket as used in cases of scoliosis, and attention may be drawn to an ingenious method for introducing the felt pads employed.

We have made some minor criticisms on what appears to us to be a thoroughly practical and useful handbook. Parts 2 and 3 might, we think, advantageously be expanded in later editions. The illustrations are numerous and carefully selected and enhance the value of the text. The volume should be in the hands of all house surgeons and senior students, and may be consulted with advantage by medical men called upon to use plaster-of-Paris. It supplies a real need and should certainly do much to popularise the use of plaster amongst those not too prejudiced to appreciate its advantages. Incidentally it should help to familiarise the student with the French technical terms and make for a highly desirable medical entente.

### *The Catarrhal and Suppurative Diseases of the Accessory Sinuses of the Nose.*

By ROSS HALL SKILLERN, M.D., Professor of Laryngology, Medico-Chirurgical College. London and Philadelphia: J. B. Lippincott Company. Pp. 418. 21s. net.

Professor Skillern's handbook on the catarrhal and suppurative diseases of the accessory sinuses of the nose was first published in 1913, and has now reached its second edition. Although the entire work has undergone a systematic revision, the original plan of the work has not been changed. The subject is dealt with in six parts. The first part is given up to general considerations; the next four parts to the maxillary, the frontal, the ethmoidal, and the sphenoidal sinuses respectively, whilst the last part deals with multiple or pansinusitis. Repetition occurs in several places, but this obviates frequent references to other portions of the book.

The greater part of the changes consist of amplification, amongst the more important of which are the following: The treatment of sinus disease in children; the use of the naso-pharyngoscope in the diagnosis of obscure conditions in the sphenoidal and posterior ethmoidal regions; and a compilation of the American mortalities following the Killian operation on the frontal sinus. The number of pages has not been materially increased. The book is profusely illustrated with 247 figures in the text and five coloured plates. It contains a good index and nearly 600 references to other authors, which make it a handbook for the student and a work of reference for the teacher.

# THE LANCET.

LONDON: SATURDAY, FEBRUARY 10, 1917.

## Economy in Food.

ON Tuesday last Mr. NEVILLE CHAMBERLAIN, in launching his scheme for National Service, alluded to plans, not yet complete, to ensure "that doctors are so mobilised and distributed that the needs of both the civil population and the Army can be met." The announcement will cause surprise to no reader of our columns, and comes at the right moment, when not only is general service seen to be the duty of citizenship, but when the nation is receiving for the first time official instructions to reduce the food consumption. Coincident with the publication of a statement on the whole subject by Lord DEVONPORT, the Food Controller, a report has been published on the food-supply of the United Kingdom, drawn up by a committee of the Royal Society at the request of the late President of the Board of Trade, Mr. RUNCIMAN. This was issued on Feb. 2nd. The signatories include the following: Dr. A. D. WALLER, professor of physiology in the University of London (chairman); Dr. W. L. ASHLEY, professor of commerce in the University of Birmingham; Mr. A. W. FLUX, of the Board of Trade; Mr. A. D. HALL, Development Commissioner; Dr. F. G. HOPKINS, professor of bio-chemistry in the University of Cambridge; Mr. T. H. MIDDLETON, Board of Agriculture; Dr. D. NOEL PATON, professor of physiology in the University of Glasgow; Dr. W. H. THOMPSON, professor of physiology in the University of Dublin; and Mr. T. B. WOOD, Drapers Professor of Agriculture in the University of Cambridge. The report is divided into three parts, which deal respectively with the food-supply of the country throughout the period of five years preceding the war; the food-supply in 1916; and the methods by which our available sources of food can be developed, utilised, and organised. It is a valuable document, which can be obtained at the Stationery Office or through any bookseller for 4d., and should receive the close study of the medical profession, who ought to be in a position to give advice to caterers, public or individual, upon the minimum requirements of food and the sources of energy production.

Turning to the statement by Lord DEVONPORT, issued on the same day as the report of the Committee of the Royal Society, we find that the Food Controller has published a clear warning declaring the existing need for food economy. At the outset the nation is asked by the Food Controller to economise voluntarily and with individual patriotic effort. If the response comes in the wholehearted way that Lord DEVONPORT hopes, compulsory rationing may be avoidable. Otherwise a compulsory system may have to be

established. The curtailment of the nation's food consumption, by whatever method it is adopted, is, in his opinion, urgent, and a real and serious attempt has got to be made in the very near future by every individual to reduce, where it is possible, his or her food allowance. The suggestion is to give up extravagance and waste rather than to relinquish actual necessities, and this opens up the subject which for long has been a matter of debate amongst physiological authorities, as to what constitutes an actual necessity. Lord DEVONPORT appeals not so much for actual sacrifice of bodily needs as for a self-imposed restraint, a practice of frugality which will ensure, he says, a sufficient supply for all. The irreducible dietetic minimum in terms of food commodities at once comes into question. Guided, no doubt, by the weight of physiological evidence and opinion at his disposal in the report to the Board of Trade, the Food Controller has put forward examples of allowances in the shape of the three staple foods—bread, meat, and sugar. After consideration of available stocks and probable means of obtaining future supplies, the situation requires, he says, that heads of families should endeavour to limit themselves to the weekly purchase for each person comprising the household of the following quantities per head per week: bread, 4 lb. (or its equivalent in flour, 3 lb., for bread-making, &c.); meat, 2½ lb.; and sugar, ½ lb. These foods are taken by him to be the cardinal factors of the situation, and it is stated that though the above quantities will form the basis of the dietary scale they will naturally be supplemented by other food products. This is an important qualification. So far, there is said, for example, nothing about barley, oats, fruits, milk, cheese, butter, and so forth, but meat includes poultry, game, bacon, sausages, and tinned meat. The ration of meat is calculated by weight as supplied by the butcher, and includes bone and fat. It is believed that a resolute effort on the part of each consumer to reduce consumption by at least 1 lb. of bread or ½ lb. of meat per week, or both, will automatically bring about a saving of over 1,000,000 tons per annum of these foods.

It is early yet to deal adequately with the physiological side of Lord DEVONPORT's proposals as they are not complete; so far they disclose only a general policy as regards the three staple commodities—bread, meat, and sugar. We recommend all our readers to consult the article by Dr. EDMUND SPRIGGS, published on p. 234 of this issue of THE LANCET, for valuable information on the subject. The question whether the daily amounts of these foods are dietetically sufficient will no doubt be discussed, as well as the allowances made in regard to supplementary articles of food. For example, when we consider in a diet the values of protein, carbohydrate, fat, and mineral substances, one or other or all of these could be presented to us in other foods not mentioned in Lord DEVONPORT's proposals, but not so obviously the staple foods of this country, while their supply is to a great extent an unknown proposition. The nation is perfectly willing to participate in a scheme involving any

self-denial which is a help and aid to those fighting for us on land and sea, and the authorities are now prepared to make clear what is expected of the people. Lord DEVONPORT has undertaken to inform the public how to economise and how to adjust individual needs to the situation as they may develop. A staff has been organised having for its object to guide the people in its eating, and weekly notices of instruction and advice will be issued. The scheme is sound enough as regards its aim, and the definite proposals made should secure immediate adherence, though everyone can see the direction in which they will press hardy. The economy in flour is drastic. The details have yet to be discussed, and probably adjustments based on the representations of scientific and economic authorities will receive careful consideration. Concerning the co-operation of the nation no misgivings need be entertained.

### National Health in 1915-1916.<sup>1</sup>

IN presenting his review of the national health in 1915-1916 Dr. NEWSHOLME discusses certain difficulties resulting from the conditions of war which have continued substantially unimproved since August, 1914. Among these difficulties he mentions, first, the serious disturbance which has affected local populations, in consequence of which the uncertainty necessarily attaching to local estimates has been greatly increased. Secondly, he refers to the creation of gigantic war industries throughout the country, which are not aimed at the national requirements after the war. At least a partial solution of the population difficulty—complicated as it has been in the past by the duplication of areas—was supplied at the recent Census by the substitution of the administrative for the registration or Poor-law area as the unit of tabulation for official purposes. By this means the statistical returns of the local medical officers of health as well as those of the Central Office at Whitehall are brought into line with the national records of Somerset House. Since the outbreak of war the work of the medical staff of the Local Government Board has centred chiefly around the military position, and this is especially true with reference to the second year of war, now under review. In his previous annual report Dr. NEWSHOLME gave account of the measures taken to safeguard the public health under exceptional conditions, as well as of the detailed co-operation arranged between the military and civil authorities. The efficiency of the collaboration is established by the present report, and admitted by the War Office. It will, we hope, be further enhanced as a result of Mr. NEVILLE CHAMBERLAIN's statement that the mobilisation of the whole medical profession is under consideration.

During 1915 a special visitation of military camps was undertaken by the medical inspectors of the Board in conference with the military

and civil sanitary officers, the medical inspectors being further engaged in discussing with their military colleagues the serious problems of camp water-supplies and sewage disposal. Throughout the year the local sanitary authorities have provided liberal accommodation in civil isolation hospitals for soldiers suffering from infectious disease. Similar preventive measures have been arranged for with the Admiralty, the medical staff of the Board having collaborated with the Admiralty officers in the inspection of naval camps and billets. Striking evidence of the success of such continued effort is furnished by the fact emphasised by Dr. NEWSHOLME that, with the sole exception of measles, communicable diseases have shown no increase during the year. The weekly incidence among military and civil populations respectively of cases of measles, enteric fever, and cerebro-spinal fever are given in the report, and the distribution in both populations of poliomyelitis is also set out. The prevalence in England and Wales of the latter two diseases forms the exception in a yearly record of infectious diseases which was otherwise favourable. Although it is known that half the children recently born still remain unprotected by vaccination, it is noteworthy that small-pox has hitherto failed to gain more than a temporary footing in any part of England. Most of the 78 cases reported during the year were definitely traced to imported infection from elsewhere. In every case the local provision for isolation seems to have been effective in preventing extension. One of the commonest accompaniments of prolonged warfare is dysentery. Unless this contagious and recurring disease, as it occurs in the field, is treated under satisfactory conditions it is liable to cause widespread mischief amongst civilian populations. It is satisfactory to learn that owing to the strenuous precautions adopted by the Army medical staff very few instances have arisen in which the disease has spread outside the military hospitals containing dysentery patients. Notwithstanding the return to this country of many soldiers recovering from dysentery, the disease is nowhere reported to have prevailed epidemically. Neither has typhus fever acquired a foothold in this country, either among the military or the civil population, in spite of the fact that the disease has been prevalent during portions of the last two years in Serbia and in certain parts of Russia as well as in several of the prisoners' camps in Germany. The infection is known to be communicated chiefly by means of body lice, and the conditions of life in camps and close billets make pediculosis difficult of control. It is therefore satisfactory to hear that the return of many thousands of troops from the various fronts has not been accompanied by spread of typhus at home. The country has also remained free from plague and from Asiatic cholera.

The best criterion of the sanitary condition of a community undoubtedly consists in the prevalence or absence of enteric fever. In 1915 the amount of this disease was so slight as to inspire hope

<sup>1</sup> Supplement to the Forty-fifth Annual Report of the Local Government Board : Report of the Medical Officer.

that enteric fever, like typhus, will ere long become practically extinct in this country. There has been in recent years a remarkable decline in the notifications of enteric fever, the numbers having fallen from 13,000 in the year 1911 to 6000 in the year under review. The extent to which decline has taken place will be appreciated from the fact that even so recently as 1893 enteric fever caused 6801 deaths, a larger number than the total of cases of enteric sickness notified in 1915. The three counties showing the highest prevalence of enteric fever are Durham, the West Riding of Yorkshire, and Northumberland, the incidence being greatest in crowded centres of population, or where elementary sanitation is notoriously defective. Cerebro-spinal fever showed exceptional activity in the year 1915, and special work was undertaken by the military and civil staffs to control its spread and to investigate its causes, in the hope that completer knowledge would lead to prevention. In his remarks on the war in relation to cerebro-spinal fever the Medical Officer to the Local Government Board mentions the occurrence of 1146 military cases in England and Wales, excluding cases originating overseas. Among the civil population 2566 attacks were notified in the year under review, as compared with 315 in the preceding year and 279 in 1913. Cerebro-spinal fever prevails chiefly in the earlier months of the year, reaching its maximum incidence in March or April. Acute anterior poliomyelitis occurred in sporadic fashion during the year. In marked contrast to cerebro-spinal fever poliomyelitis is essentially a summer disease, and although in this country the disease has never assumed epidemic proportions, it occurs here annually in considerable amount. In 1915 the reported cases numbered 517, as against 509 in the previous year, and 744 in 1913. From inquiries concerning local outbreaks but little evidence emerges of the spread of infection from person to person, but this is a line of investigation that no doubt awaits pursuit when the personnel of the Local Government Board is less depleted. Despite the shortage of officers, however, the control of pulmonary tuberculosis has received special attention during the year. In certain districts the entire staffs of tuberculosis officers have been detached for military service, their places being often taken by female medical officers or by general practitioners. The number of beds available in residential institutions for the treatment of this disease exceeded 11,000 in the spring of last year. This number would have proved insufficient but for the fact that tuberculous persons enjoying the high wages of war-time have frequently been unwilling to submit to isolation in sanatoriums. In the majority of counties there is still a shortage of hospital beds for advanced cases of phthisis. It is noteworthy that whenever a soldier is discharged from the service on account of tuberculosis the fact is promptly reported to the medical officer of health of the district to which the soldier is proceeding. In all cases, therefore, tuberculous ex-soldiers are brought under the supervision of the sanitary authorities. With regard

to the compulsory isolation and detention of tuberculous persons, which has been tried at St. Helens and suggested in other places, Dr. NEWSHOLME is of opinion that it would be contrary to the public interest that such powers should be entrusted to a local authority unprovided with an adequate supply of beds for the treatment of advanced cases of consumption.

Public health work is not restricted to the control of disease communicable by infection. It embraces all measures, whether of prevention or of treatment, by which the health of the community may be improved. Second only to the work directly arising out of war conditions the attention of the Board's medical department has been occupied throughout the year in considerations for maternity and child welfare. The need for increased effort to save child life is shown by the perilous fall in the natural increase of the population. In England and Wales during the year 1914 there were 362,354 more births than deaths. In the year 1915 the excess of births over deaths was only 252,201. There were 64,569 fewer births and 45,584 more deaths in 1915 than in the preceding year. The reduction in the number of births emphasizes the importance of saving life and of improving the health of all survivors. "There is no insuperable difficulty," writes Dr. NEWSHOLME, "in reducing the total deaths in childhood to one-half their present number." There are at present in England and Wales about 1000 salaried health visitors, the number having increased by 400 since the commencement of the war. The practicability of extended work of this kind has been increased by the passing of the Notification of Births Extension Act of 1915, which gave to county councils the powers of a sanitary authority for the purposes of the care of expectant mothers, nursing mothers, and young children. About half the county councils and most of the county boroughs have adopted schemes under the Act, and many of these are in actual operation. As an unfortunate effect of the war there has not been an expansion of voluntary work for child welfare to the same extent as of official work, the subscriptions of voluntary societies having fallen off. The urgency for more definite action on the part of public authorities is therefore considerably increased.

### The Control of Cerebro-spinal Fever.

Cerebro-spinal fever has always shown a special liability to attack military forces, and considerable apprehension naturally arose over the state of affairs in this country a few months after the outbreak of war, when hundreds of camps filled with recruits at a susceptible age were scattered everywhere. The severity of the recent outbreaks is well shown in the diagram given by Dr. NEWSHOLME in his report. Early in 1915 it became apparent that an epidemic of this disease was imminent, and the curve reached its maximum in March and April of that year. 2566 civil and 1146 military cases were

reported in the course of the year, as compared with a total of 279 in 1913. In 1916 the epidemic curve reached only about half the height of that attained in 1915, and there is good ground for the hope that 1917 may witness a further decrease. At the outset Colonel W. H. HORROCKS and Colonel R. J. REECE were placed in charge of the military administrative measures for dealing with the disease, and it soon became apparent that bacteriological advice and assistance upon a large scale were required if the epidemic was to be controlled. The Medical Research Committee undertook to provide the scientific assistance required, and placed Lieutenant-Colonel MERVYN GORDON at the head of the bacteriological organisation. A central cerebro-spinal fever laboratory was established at Millbank, where Major T. G. M. HINE assisted, and numerous provincial laboratories were set up at suitable centres. An analysis of the reports from these centres made by a small committee of bacteriologists was published a year ago, and this year Lieutenant-Colonel GORDON issues a report on work done at Millbank, detailing the methods devised for the control of cerebro-spinal fever during the past two years and giving some indications of the results which have already been achieved. To the painstaking experimental work on which preventive measures have been based, and for which great credit is due to Lieutenant-Colonel GORDON and his colleagues, we desire to draw special attention, and, in particular, to two outstanding features of it: (1) the serological recognition of the type of meningococcus as a guide to isolation of positive contacts; and (2) a method for the treatment of such contacts.

The spread of cerebro-spinal fever is by healthy persons who carry the meningococcus in the naso-pharynx, themselves escaping the disease, and it is estimated that some 2 per cent. of the population may be carriers under ordinary circumstances, while at certain times and in certain districts the percentage may be much higher. The proportion of carriers who develop the disease is an extremely small one. Captain SHEFFIELD NEAVE, who writes in this issue of an epidemic in East Suffolk numbering 73 cases, says: "No contacts were known to catch the disease." The insidious mode of spread accounts for the discontinuity usually observed in cases of cerebro-spinal fever, and renders the disease exceedingly difficult to control. More than one type of meningococcus may be concerned in producing the disease, and the term parameningococcus has been introduced for that type which showed serological nonconformity with the classical organism. The first important research undertaken by Lieutenant-Colonel GORDON, after surmounting initial difficulties, was a serological investigation into the strains of meningococcus concerned in the existing epidemic. Taking as his criteria the phenomena of agglutination with specially prepared univalent sera, and in particular the power of absorbing specific agglutinins, he found that the races of the microbe identified in the cerebro spinal fluid in the epidemic of 1915 fell into four groups, which were similarly encountered in last year's epidemic. He

termed them Types I., II., III., and IV., and proved them to breed true and to remain unaltered in their serological characters after a year's culture. In any given case only one type has been detected, and always a single type in both naso-pharynx and cerebro-spinal fluid of a particular patient. The close contacts of a case have also usually harboured the same type as the affected individual. The term "epidemic type" suggested by Lieutenant-Colonel GORDON seems a justifiable one.

The practical difficulty confronting those who were endeavouring to control the spread of the disease amongst the military forces was that the isolation of the numerous positive contacts involved serious interference with the necessary training of healthy men. Now in investigating naso-pharyngeal strains of the meningococcus, both in contacts and non-contacts, it had been seen that quite a considerable proportion of them did not correspond serologically with the epidemic types. It was therefore determined to segregate only those positive contacts who were ascertained to be carrying meningococci of the epidemic types. The reduction in numbers thus effected had the immediate result of rendering practicable the policy of temporary isolation. It may be admitted that this procedure is not perfect, but from the examples given in Lieutenant-Colonel GORDON's report it appears to have met with considerable success. Thus, to quote a single example, Captain R. R. ARMSTRONG swabbed no less than 10,000 men and provisionally isolated 410 as carriers of an organism resembling the meningococcus. Lieutenant W. J. TULLOCH subsequently examined 324 serologically (the remainder having meanwhile become free of the coccus) and was able to release 103 of them on the agglutination results. No evidence came to hand that any single man of this infected garrison passed as negative by Captain ARMSTRONG either developed the disease or passed it on to another. Whilst attended with such success in military practice it is nevertheless obvious that this mode of controlling cerebro-spinal fever is not readily applicable to civil practice.

Having weeded out the probably important carriers, Lieutenant-Colonel GORDON went on to perfect a new method of curing them. While the majority of carriers rid themselves of their meningococci in a week or two, a certain number retain them for weeks or months, and no method of cure has hitherto met with much success. Trials were made by saturating the air of a small room with extremely fine droplets of a disinfectant, as had previously been done by KÜSTER. A Lingner spray was first used, but was later replaced by an apparatus designed by Second Lieutenant E. GORDON, R.E., which proved more efficient and is fully described and figured in the report. The first disinfectant chosen for trial proved the best. It was toluene-sodium-sulphochloramide, briefly known as chloramine-T, a substance prepared by Dr. DAKIN and Professor COHEN in the course of researches upon the mode of action of the hypochlorites. It is non-toxic and does not coagulate albumin. The air so saturated was found to sterilise plate cultures of staphylococci and yet to be tolerated by human

beings for 15 or 20 minutes. A group of 14 chronic carriers received the treatment daily, and all but 3 were cured after at most 13 daily inhalations, though some had been carriers for 10, 12, and even 17 weeks. Later trials were made with zinc sulphate in place of chloramine, but the results were much less satisfactory. Chloramine treatment appears to offer a better prospect of quickly curing the carrier condition than any which has yet been tried. Besides these two important investigations the report contains a large amount of valuable detail, notably in Captain M. FLACK'S report on his work in the London district during 1916. As a whole, it deserves careful study and is encouraging as an earnest of further progress.

## Annotations.

"Ne quid nimis."

### STOCK MIXTURES.

THE advantages and disadvantages of stock mixtures have long been discussed from many different points of view. Teachers and examiners unite in condemning their employment in spite of their convenience. It is often asserted that the use of stock mixtures in hospitals tends to foster careless disregard of many opportunities. Students may get into a habit of writing the name of a stock mixture and yet be profoundly ignorant of all that the name implies. They may occasionally refer to the hospital pharmacopoeia for information, but it is exceptional for them to memorise the full list of the ingredients or the proportions in which they are present in the single dose. Hence the sense of bewilderment which is so often felt when the sphere of activity is changed and the appropriate prescription is required at short notice. Hence also the complaint so often heard from examiners about the lost art of prescribing. On the other hand, there is no denying the practical advantages of stock mixtures for those who have to dispense for large numbers in a limited time. In hospitals with huge out-patient departments it is inevitable that stock mixtures must be used so as to prevent undesirable congestion of work. For the convenience of students the key or clue is the hospital pharmacopoeia, with prescriptions arranged in single doses, and it is left to the dispensing staff to do the necessary calculations when preparing any required quantity of stock.

Viewing the dispensing under the National Health Insurance Act as analogous to a provision for out-patient treatment on an extensive scale, the Insurance Commissioners have issued a revised list of mixtures which are capable of being stocked in bulk without deterioration. According to a note in the *Pharmaceutical Journal*, the revision consists in the adjustment of the proportions of ingredients in each mixture to an 80 fluid-ounce bulk quantity. In other respects this formulary is identical with that issued in the spring of 1916. All medical practitioners engaged in panel practice will have to familiarise themselves with this list, and no doubt will find some interest in endeavouring to calculate back the quantity of each ingredient in a dose of half a fluid ounce. The calculation will be greatly facilitated by bearing in mind the number of grains

in the avoirdupois ounce—namely, 437·5. The list comprises 28 mixtures, and to these names have been given without any definite principle. Sometimes the most important ingredient is mentioned alone; occasionally the names of two appear together. Thus we find *mistura bismuthi*, *mistura colchici*, *mistura copaibæ*, or again *mistura ammoniæ et senegæ*, *mistura ferri et quassiae*, *mistura sodæ c. rheo*. It used to be considered a golden rule that the name of a mixture should have no reference to the supposed action, but in the list this rule has been transgressed repeatedly; thus we meet with *mistura astringens*, *mistura carminativa*, *mistura diuretica*, *mistura expectorans*, and so on. While the various ingredients of these mixtures have obviously been carefully selected with primary reference to the avoidance of deterioration, it is satisfactory to note the wide range of really useful remedies capable of inclusion. The compilers have not felt bound to galenicals mentioned in the British Pharmacopoeia, but have dipped into the Pharmacopoeia of the United States for a liquid extract of colchicum seeds and a liquid extract of senega root. They have also drawn on the British Pharmaceutical Codex for an emulsion of chloroform which appears in 9 of the 28 mixtures, and from the same source, without acknowledgment, they have derived the *liq. cocci*. Apart from the small amount of tincture of *quillaia* (2 per cent.) present in the emulsion of chloroform, and the liquor *cocci* in *mistura tussis*, each fluid ounce containing 1 minim of a solution of 20 per cent. of alcohol, alcohol is noteworthy by its relative absence in these stock mixtures. *Tinctura camphoræ composita* and *tinctura opii* are the only other representatives, and these are certainly not included for any preservative action of the alcohol. In natural contrast to the prescriptions commonly met with, we have to note the absence of sugar, with the exception of that contained in *pulv. cretæ aromat.*, and of syrup, which is represented only in the *mistura tussis*.

It is stated that this list has been "agreed" on by the British Medical Association and the Pharmaceutical Society of Great Britain, or "adjudged" by the Insurance Commissioners, and congratulations are due upon the general excellence of the work. One mixture, however, has already afforded an occasion for mirth. It contains six ingredients, of which three are powdered vegetable drugs; a pharmacist's assistant suggests that this compound is the idea of a doctor who hides his identity, and there is no clue whether the praise or blame is to be awarded to the two bodies who "agreed," or to which one of them, with the Insurance Commissioners who "adjudged." This is a pity, as otherwise some information might be given about the mode of securing suspension of these powders.

### SIMULATED JAUNDICE FROM PICRIC ACID.

IT may be interesting at this time, when subterfuges may in some few instances be resorted to in order to escape the obligations of duty to the State in respect to military service, to draw attention to a new method of detecting picric acid in the blood in cases of simulated jaundice. Dr. L. Tixier and Dr. A. Bernard publish such a method in the *Progrès Médical*, Nov. 20th, 1916, and its advantages lie in the fact that it is simple and requires only a small quantity of blood taken from a finger tip, and a further merit consists in the possibility of the test being applied as late as three weeks after the picric acid has been taken. The

method advocated by these observers is as follows: 15 drops of blood from the finger are received into a test-tube containing 3 c.c saline solution 95 per cent., and well shaken twice or thrice at intervals of an hour in order to facilitate separation and contraction of the clot. The test-tube is then allowed to remain 24 hours at the ordinary temperature. A certain number of globules fall to the bottom, while the rest remain entangled in the clot. From 1 to 2 c.c. of the saline solution in the neighbourhood of the clot are then taken out by a pipette. This fluid is coloured faintly with yellow in cases of picric jaundice; an equal quantity of a 1 in 50,000 solution of methylene-blue is then added and vigorously shaken. After an hour from 10 to 15 drops of chloroform are added and after shaking are allowed to subside to the bottom of the tube. If the picric acid is present in considerable amount the chloroform takes a dark bottle-green tint, in smaller quantities a pale green. The same experiment performed on 24 patients suffering from catarrhal jaundice gave no reaction.

#### THE LAW AND THE DOCTOR.

We have received a copy of an address delivered before the Academy of Medicine, Toronto, by Mr. Justice W. R. Riddell, a judge of the Supreme Court of Ontario, under the above title. The subject would appear to be a large one for treatment in a single discourse, and the lecturer has not unnaturally found himself drawn into the discussion of the more obvious points at which the law and the doctor come into contact, or, not infrequently, into collision. Equally naturally a prominent place is assigned to those doubts and questionings which arise in circumstances likely to lead to such contact or collision. Instances of these occur when a medical man finds himself, in consequence of professional attendance upon a patient, the receptacle of a secret, the revealing of which might expose his patient to prosecution, whereas the concealment of it might subject the medical practitioner to blame, if not to the suggestion of criminality on his part. There are also cases in which the medical man has become acquainted with facts which, if made known in a court of law, might affect the result of a civil action. The lecturer illustrates cases where crime is involved with concrete examples, such as the visit to a doctor of an injured man who states that his hurts are due to his having been interrupted when committing a burglary. Another slightly different example given by him is the familiar one of the medical man who attends a woman who has aborted, and who is told nothing, but suspects that there has been criminal interference which has caused her condition. The Canadian judge propounds in the latter case the question whether the medical man should make no inquiries or should try to find out who performed the illegal operation. He gives the same advice in both instances that the medical man is in no different position from the layman and that he should look at the matter from the point of view of a "good citizen," or in the case of the woman as if he were a "friend" instead of a "doctor." We are, however, disposed to consider such comparisons to be misleading and to point out that the medical man is in a totally different position from any layman. He is consulted in consequence of his practice of a certain profession, and consequently is far more often exposed to the dangers and difficulties which

confidences of the kind indicated must involve; he can have no feelings of friendship towards a patient who is a stranger, but he has the general ethical rules of his profession forbidding him to reveal his patient's secret; he, further, has knowledge of facts in which the law would be interested such as no layman would possess, whether the latter became the confidant of a burglar or formed the opinion that a woman had been the prey of an abortionist. The medical man occupies, in short, an exceptional and altogether peculiar position. The law affords him no special protection or privilege; in this our courts and those of Canada apparently agree. Equally, however, in Canada and here, the medical man is treated usually with consideration as a witness, where the revelation of professional confidences is involved, and if a judge decides that in accordance with the law, and to further justice, he must break silence, none should blame him for obeying the law of his country. He will, however, be well advised if, in attending all patients, he avoids by every means in his power being made the recipient of confidences not necessary to assist him in the treatment of the case before him. It is obvious also that he should allow no one to know that any such confidences have been imparted to him, or even that he may possess knowledge professionally acquired the revelation of which would damage his patient. As a general rule, also, he should remember that his duties are those of a medical man, not a detective. The obligation to maintain secrecy with regard to his patient's affairs may, however, be relaxed in one respect; when he feels it to be desirable for his own guidance he should obtain advice as to what his conduct should be, and no one will blame him if he consults a brother practitioner. To do so will strengthen his own position, if his actions should ever be impugned, by securing for him a witness who will testify to his good faith and to the correctness of his conduct.

#### SYPHILIS WITHOUT CHANCRE IN WOMEN.

THE occasional absence of chancre in certain cases of syphilis, particularly in women, has long been recognised. At a recent meeting of the Académie de Médecine of Paris Professor Gaucher brought forward an interesting view of this phenomenon. Chancre being simply the reaction of the epidermis attacked by the virus, it is obvious that if the inoculation takes place more deeply, by introduction of the virus into the general circulation, the reaction will be absent. Professor Gaucher gave as an example the case of a surgeon who in operating on a syphilitic patient wounded himself deeply with a bistoury. He never had a chancre, but six weeks later the roseola appeared. Another case was related to him by the late Professor Fournier. At the Saint Louis Hospital psoriasis was being treated by intramuscular injections of yellow oxide of mercury. One day a patient suffering from psoriaform syphilis, which was mistaken for psoriasis, was injected. The same needle was used to inject a patient suffering from psoriasis and six weeks later the roseola appeared. In women Professor Gaucher admits that the chancre is frequently overlooked and cannot be found if the examination is not made until the end of two or three months, although in men the chancre does not usually spontaneously heal so quickly. But there are indisputable cases in which a man has contracted a chancre in extra-marital relations, has had intercourse with his wife before he knew he was infected, and, when enlightened as to

the danger, has had her examined as often as four or five times in a month. Although the external genitals, vagina, and cervix have been examined with the greatest care and nothing has been found, yet secondary symptoms have appeared a few weeks later. In such cases Professor Gaucher not only has failed to find a chancre, but even any enlargement of lymphatic glands. His explanation is as follows. Chancre can exist only on the skin or on the mucous membranes covered with stratified epithelium, such as the mouth, prepuce, vagina, and anus, which are all derived from the skin. Rectal chancres may be urged as an objection, but Professor Gaucher thinks that these would be more correctly described as chancres of the upper part of the anus. All these surfaces are not absorbent of liquids, while the mucous membrane covered with columnar epithelium is. Professor Gaucher therefore suggests that in the cases of syphilis in women without chancre the virus is carried into the uterus. If impregnation takes place the woman, of course, is infected through the foetus. But if it does not, she can still be infected—by absorption of the virus through the mucous membrane. These cases of "spermatic infection" show certain characteristics. Like conceptual syphilis, the disease remains latent or progresses slowly without any great outbursts, and manifests itself by late lesions. Thus a woman who had not suffered in any way previously showed gummatous on the legs 30 years after marriage. The husband admitted that he had syphilis 10 years before marriage, but for a long time before marriage he had no ulcer or contagious lesion of any kind. Pregnancy never occurred. Another woman was seen for leucoplakia of the tongue, and a third for disseminated sclerosis with a similar history. —

#### ECONOMY IN GLYCÉRINE AND SUGAR FOR MEDICINAL USE.

OUR readers know well enough the great national call there is on glycerine for the manufacture of munitions of war and also the shortage of sugar owing to reduced importation, and they will appreciate any information as to how these commodities may be spared by the use of substitutes which, in the majority of cases, may be made to serve the same purpose. It is well known, for example, that substances for which glycerine is ordinarily used as a solvent are usually sufficiently soluble for all practical purposes in other media, while chloroform water is an excellent sweetener as well as preservative. As a demulcent glycerine can be replaced by a number of mucilaginous substances available, while as a laxative the resources under this category are so numerous as to put glycerine out of court for the purpose, except, it may be, in very special circumstances. Similarly, as an ingredient of lotions and douches, other solutions, saline and alkaline, are equally effective. As regards sugar as a flavouring agent, it can be spared easily and replaced by chloroform water, aromatics, and other well-known agents which serve to mask disagreeable flavours. In regard to other drugs, in connexion with which it is well that caution should be observed, it may be noted that veronal, carbolic acid, paraldehyde, phenacetin, and phenazone are still in short supply, while atropine, lanoline, the salicylate group, and thymol are now being made in this country in considerable quantities. High prices, however, still prevail, and it is desirable that the use of these drugs, in the interests of economy,

should be confined to urgent cases. Eucaine and novocaine are being manufactured on a substantial scale in this country, and these valuable drugs may be used with some freedom where their application is indicated. —

#### DERCUM'S DISEASE: ADIPOSIS DOLOROSA.

Two cases of this rare condition have recently been published in the Italian medical press, one by Dr. F. Alzona in *Il Policlinico* (Medical Section, Dec. 1st, 1916) and the other by Dr. A. Balliano in *Il Morgagni* (Archives, Nov. 30th, 1916). First described by Dercum in 1888, an American observer who drew attention to the two fundamental characteristics of the disease—increase of fat and painfulness; the symptom-group was amplified later on by Vitant with the addition of the following—muscular asthenia and psychical changes. Similar conditions had previously been described in this country by Baker and Bowlby in 1886. Some authors have stated that the condition is more frequent in women, but statistics are still uncertain, perhaps because patients in many instances do not suffer much from the disease, especially when the pain is bearable and the psychic disturbances do not exceed certain limits; the condition is discovered in most cases when medical advice is being sought for extraneous reasons. While non-painful adiposity is more often hereditary, Dercum's disease is always acquired and usually develops between the ages of 15 and 40 years, an onset before or after these ages being relatively infrequent. Two forms have been distinguished, the nodular and the diffuse; both patients, however, described by the two Italian observers belonged to the former category, both were males 26 and 38 years of age, and presented painful subcutaneous fatty nodules, chiefly on the thorax and thighs, varying in size from a grain of rice to a goose's egg, roughly symmetrical in distribution and painful not only on pressure but spontaneously. Neither case presented any conspicuous muscular debility, nor were any marked psychic changes noticed, albeit both men were rather apathetic and taciturn. Bioscopical examination of some of the tumours in both cases showed, in sections stained with osmic acid, Sudan III., and eosin-hæmatoxylin, apparently normal adipose tissue, surrounded by a thin connective-tissue capsule richly vascular, but, on the other hand, poorly furnished with nerve elements which were, however, free from any appreciable change. Three theories have been advanced to explain the pathology of Dercum's disease; they have had various advocates and may be summarised under three heads: (1) the nerve theory, which attributes the essential factor to a neuritis; (2) the theory of changes in the internal secretions, founded on alterations observed in the pituitary, thyroid, testicular, and ovarian glands; and (3) the theory of a dystrophy of the endocrine-sympathetic system. A sidelight is thrown on these theories by the cases described by Dr. Alzona. The patient had been an hystero-epileptic, presenting extensive sensory disturbances, and the beginning of the disease coincided with a period of his life when he was the subject of violent emotional crises. Moreover, experiments with a view to ascertain his reaction to adrenalin, atropine, and pilocarpine revealed the fact that whereas in the first two the reaction was negligible, in the case of pilocarpine it was very marked, characterised by increased cardiac pulsation, nausea, profuse salivation, and sweating. The theory of

an endocrine-sympathetic dystrophy is one which fits in best with the symptom-group of Dercum's disease. It is difficult to find an adequate explanation of the phenomena in abnormality of the thyroid or pituitary functions alone, and to bring fresh light on to this obscure question further pathological researches are needed with a view to investigate the functional of the nervous system on the one hand, and the endocrinic apparatus on the other.

#### RICHARD LIEBREICH.

Dr. Richard Liebreich, who died in Paris on Jan. 29th in his eighty-eighth year, was oculist to St. Thomas's Hospital, London, before Nettleship, but became a naturalised Frenchman more than 50 years ago. With the possible exception of Zehender, he was the oldest living oculist, his first contribution being in 1857 on the use of the ophthalmoscope, in a translation, published in Brussels, of William MacKenzie's great work on the eye. The longest of his own writings was on amaurosis and amblyopia in a dictionary of practical medicine published by Messrs. J. B. Bailliére et Fils in 1864. Liebreich had some little reputation as a painter and sculptor, and a series of lectures on Turner and Mulready, delivered in the "eighties," was reprinted by Messrs. J. and A. Churchill.

#### THE ROYAL SOCIETY OF MEDICINE AND THE NAVAL AND MILITARY MEDICAL SERVICES.

We have had frequent occasion to note that commissioned officers of the Naval and Military Medical Services are unaware of the cordial invitation extended to them by the Council of the Royal Society of Medicine to make free use, when in London, of the Society's Rooms, and to use the library for purposes of reading and reference. Rooms are set apart for writing, smoking, tea, conference, and dressing. They are further welcome to attend any of the numerous meetings which are held for papers and discussions, as announced from week to week in the medical press. The society's house (1, Wimpole-street, Cavendish-square, W.) is open from 11 A.M. to 6.30 P.M.

AT the Royal College of Surgeons of England next week Surgeon-General Sir George Makins will deliver (Wednesday, Feb. 14th) the Hunterian oration on Hunter's Influence upon Military Surgery; Professor J. Hutchinson will deal with Dupuytren's Contraction in his Hunterian lecture on Monday, Feb. 12th; and Professor W. Sampson Haudley with Paget's Disease of the Nipple on Friday, Feb. 16th. In the following week Professor R. H. Elliot will deliver (Monday, Feb. 19th, and Wednesday, Feb. 21st) two Hunterian lectures on Couching for Cataract in India. The lecture hour in each case is 5 P.M.

#### THE LANCET, VOL. II., 1916: THE INDEX

OWING to the continued shortage in the paper-supply the Index and Title-page to the volume of THE LANCET which was completed with the issue of Dec. 30th, 1916, have been printed separately, and copies have been supplied gratis to those subscribers who have, up to Feb. 8th, intimated to us their wish to receive them. Other subscribers will be similarly supplied, so long as the stock remains unexhausted, on application to the Manager, THE LANCET Office, 423, Strand, London, W.C. Such applications should be sent in at once.

**THE FOOD OF THE NATION.**

BY EDMUND I. SPRIGGS, M.D. LOND., F.R.C.P. LOND.,  
SENIOR PHYSICIAN, DUFF HOUSE, BANFF; LATE SENIOR ASSISTANT  
PHYSICIAN TO ST. GEORGE'S HOSPITAL AND DEAN OF  
THE MEDICAL SCHOOL.

THE manifesto of the Food Controller which was published on Feb. 1st was received by the press and people with much interest and enthusiasm. Lord Devonport asked the nation to confine itself to a measured quantity per head of three important foodstuffs, leaving it to the discretion of each housewife to make up the diet of the family with other materials. On the same day a White Paper was published, containing a Report on the Food-Supply of the United Kingdom drawn up by a committee of the Royal Society at the request of Mr. Rucliman, late President of the Board of Trade. The committee included the professors of physiology in the Universities of London, Glasgow, and Dublin, and the professor of bio-chemistry in the University of Cambridge. The first and second parts of the report are dated July, 1916; the third part bears date December, 1916.

The report is of great interest. It contains the statistics upon which we presume that the Ministry of Food based its deliberations, though no doubt more recent figures are now in their possession. The matter is of such importance, and especially to medical men, whose advice is being sought all over the country in the matter of diet, that it may be well to review the main features of the report before considering the manifesto.

Those who have read the small book on the food-supply of Germany<sup>1</sup> compiled by a committee of German professors, an abstract of which appeared in THE LANCET of Feb. 20th, 1915, or its translation by Dr. Russell Wells,<sup>2</sup> will recognise some familiar features in the White Paper, as is indeed to be expected. The differences are perhaps more interesting than the similarities, for the problem in Great Britain is not the same as the problem in Germany, either as regards the quantity or the nature of the foods concerned.

The report begins with an examination of the amount of food materials available for consumption by the population of the United Kingdom in the five years preceding the war, based upon figures supplied by the Board of Trade. The table shows the proportion of each food which was home-grown and the proportion which was imported. The total supply of food yielded an annual average of 51 millions of calories, which gives 3091 calories per head per day.

Children are, of course, included in the counting of heads, and in order to avoid confusion on this account the committee, as is done in the Elitzbacher report, has calculated the population in terms of "men" on a scale which ascribes values to children according to their age, and regards a woman as eating four-fifths as much food as a man. In receding diet on this scale 100 men, women, and children, on the basis of their proportions in this country in the year 1911, are equal to 77 adult units or "men."

The food-supply per "man" is, therefore, greater than the food-supply per head. It works out, in the years 1909-13, at just over 4000 calories per "man" per day, made up of 113 grammes of protein, 571 grammes of carbohydrate, and 130 grammes of fat. An independent estimate by Professor W. H. Thompson (Appendix I. B.) gives substantially similar figures—namely, 3361 calories per "man" per day, with 111 grammes of protein, 549 grammes of carbohydrate, and 125 grammes of fat.

The committee set forth that the "dietary requirements of a nation for the most part engaged in active work ..... cannot be satisfactorily met on a less supply in the food as purchased than 100 grammes protein, 100 grammes fat, 500 grammes carbohydrate, equal approximately to 3400 calories per 'man' per day, a 'man' being an average workman doing an average day's work."

It appears, therefore, that the supply of food has not only met the national needs in the past, but has exceeded them, the margin of excess or waste being at least 10 per cent, in the case of protein and carbohydrate and as much as 25 per cent. in the case of fat.

<sup>1</sup> The Food-supply of the United Kingdom. Published by H.M. Stationery Office, 1917.  
<sup>2</sup> "Die deutsche Vorkriegsernährung und der englische Ausungerungsplan," 1915, edited by Professor Paul Kitzbacher.  
<sup>3</sup> English translation by S. Russell Wells, M.D., "Germany's Food, Can it Last?" University of London Press, 1915.

Before leaving this, the first part of the report, it is of interest and, indeed, of importance at the present time to take note of what share each kind of foodstuff contributes to the total caloric value of the food. The following figures in column 1 are taken from Table I. of the report, but their order is altered, those foods being put first which yield most energy. I add a column (2) showing what percentage of the total caloric yield is furnished by each.

*Table Showing the Annual Yield of Calories of the Chief Classes of Foodstuffs in the Years 1909-13, with the Percentage of Total Energy Furnished by Each Class.*

	Energy value. Millions of calories.	Percentage of total supply.
Cereals	17,712,000	34·7
Meat	8,890,000	17·4
Dairy produce (including lard and margarine)	8,253,000	16·2
Sugar (including cocoa and chocolate)	6,633,000	13·0
Vegetables	4,812,000	9·4
Cottage and farm produce not included above	2,655,000	5·2
Fruit	1,077,000	2·1
Fish	531,000	1·0
Poultry and eggs, game and rabbits	461,000	0·9
Total	51,024,000	99·9

The chief cereal foodstuff is, of course, wheat. It can be seen from the details in Appendix I. A that if other cereals are left out of account, 30·8 per cent. of the total energy is furnished by wheat alone.

A consideration of the table shows that in the five years preceding the war 61·2 per cent. of the total food value of the nation was provided by three foods alone—namely, wheat (30·8 per cent.), meat (17·4 per cent.), and sugar (13 per cent.). A further 25 per cent. was furnished by dairy produce and vegetables, whilst other foodstuffs, including fruit, fish, poultry, eggs, game, rabbits, and all cereals except wheat, furnished only 13·4 per cent. of the total food energy.

Part II. deals with the food supply during the war. After considering information furnished to them by the Board of Trade and the Board of Agriculture, and comparing the supply with the estimated population in 1916, the committee reported that the main foodstuffs, meat, wheat, fish and sugar, showed a small increase during the year ending June, 1916, as compared with pre-war conditions, and that they had no evidence that the supplies of other foods were diminished.

They point out, however, that "the needs of our armies, the decreased yield of the harvest at home in 1916, and possible interference with our supplies from abroad, may reduce the supply in future below this level." They lay also proper stress on the fact that "in buying food the labouring population is buying energy," and that "a slight reduction of food below the necessary amount causes a large diminution in the working efficiency of the individual."

An appendix dealing with Army rations shows that the troops are receiving a value of 4334 calories, which at the front, with extras, may be increased to 4644 calories, including 164 grammes of protein and 205 grammes of fat. This is, as it should be, a suitable and liberal allowance for those doing hard muscular work and exposed to cold.

In Part III. the committee discuss possible methods of economising the available food-supply. Their recommendations as to the milling of flour and the use of food materials in brewing have already in whole or in part been carried into effect. In a short appendix upon alcohol they point out that whilst alcohol in moderate doses is burnt in the body, it has "effects as a drug which cannot be ignored in appraising its value as a food," and that "repeated experience has shown that regiments not supplied with alcohol marched farther, and were in better condition at the end of the day, than others to which it had been given."

Further points of importance are suggested. A more economical production may be obtained by killing beef when it is younger; the best use of fodder, however, is not obtained by feeding bullocks, for three times the number of calories may be obtained per unit of fodder by feeding good cows for their milk or feeding pigs. A considerable gain of protein would also result if milk were used for making cheese rather than for making butter.

Turning now to the manifesto of Feb. 3rd, it is first to be noted that the quantities of the main foodstuffs recommended—namely, 3 lb. of flour, 2½ lb. of meat, and ½ lb. of sugar—are for each head of the population per week, including children. In order to calculate how far they meet the needs of the body, we may convert the figures into quantities per "man." In the report of the Committee of the Royal Society the population in 1916 is estimated as 46·5 million, equivalent, at a man-value of 0·77, to 35·8 million adults or "men." If 4,000,000 men are subtracted as being fed from army rations the number of civilian "men" to be fed is 31·8 million, and the number of civilian heads is 42·5 million. The ratio between population and man value is therefore 42·5 : 31·8, and the allowance per "man" of the civilian population will be 4 lb. of flour, 3·34 lb. of meat, and 1 lb. of sugar. These are the full quantities for an adult man; a woman should have four-fifths of them and children somewhat smaller proportions according to their age. The share of a child between 6 and 9 years old would be half the adult quantities. Children over 13 need as much, on the average, as a woman.

The corrected allowance gives the following values per "man" per day:

Food per week.	Food per day.					
	lb.	oz.	Grammes	Calories.	Protein.	Carbo-hydrate.
Flour, 4 ...	9·1	258	939	29	194	3
Meat, 3½ ...	7·6	216	540	41	—	40
Sugar, 1 ...	2·3	65	267	—	65	—
Total ...	...	...	1746	70	259	43

The figures used for the composition of flour are those in Appendix I. B. of the Committee's report. I have taken meat as containing protein 18·9 per cent., fat 18·5 per cent., giving 250 calories per 100 grammes. This is a fairly average figure for meat, whether beef, mutton, or lamb.

The dietary requirements of an adult are taken in the report, as mentioned above, to be 3400 calories with 100 grammes of protein per "man." We see, therefore, that the flour, meat, and sugar allowed by the manifesto supplies a little over one-half of the food which an average man doing work needs.

The ration contains a good proportion of protein; indeed, we need not consider protein further, for in an ordinary mixed diet, if the calories are sufficient, there is generally enough of it. Only when there is grave shortage of bread, meat, and milk, does the protein in a ration run low. The same may be said of fat. I have shown above that over 77 per cent. of the total food in the country in 1916 consisted of wheat, meat, dairy products, and sugar. These are the available foods, and their composition is such that if enough calories are supplied the proportion of protein and fat will be adequate, assuming a fairly equal distribution of food-stuffs.

If the diet is to be made up to the standard there remain to be supplied from other foods 1654 calories.

The common available foods from which the balance of the diet must be made up are: oatmeal, barley-meal, tapioca, sago, arrowroot, rice, eggs, fish, milk, butter, margarine, lard, cheese, potatoes, peas, beans, and lentils.

We can estimate roughly what quantities of other foods have been available up to the present by comparing the average annual amounts given in the report with the returns which the Government has just published<sup>4</sup> of the imports for 1916. If we assume, in the absence of other information, that the country is producing about the same quantity of food, or at all events not less than the average, the chief variation will be in imports.

By adding on the imports in 1916 to the average produced in former years an estimate has been made in the case of every one of the above foods. A proportion of these foods will be required, of course, for the Army, and in order to be on the safe side I have counted the army as containing 5,000,000 men. After subtracting their share the figures given in the table below were obtained.

The comparatively small quantity of maize is left out of calculation, as are fruits. Fruits furnished 2 per cent. of our

\* Accounts relating to trade and navigation. H.M. Stationery Office, December, 1916.

supply of energy before the war, but the imported total exceeded greatly the total amount produced at home and we may suppose that they will be available in smaller quantities. Other vegetables than potatoes, beans, peas, and lentils are omitted as, though valuable in a diet, their food content is low.

These figures are not accurate. They are an estimate from such sources of information as are open to the public. But unless there has been a large increase in the production of these accessory foodstuffs it is improbable that their total value exceeds that given.

	Estimated amount available for civilians—metric tons.	32,000,000 ÷ 365 = grammes per day per man.	Calories	Protein	Carbohydrate	Fat.
Oatmeal ... ...	168,500	14·4	59	2·3	9·7	1·0
Barley-meal ...	21,600	1·8	6	0·2	1·3	—
Rice ... ...	380,500	32·6	117	2·6	25·8	0·1
Fish ... ...	735,600	63·0	37	6·3	—	1·3
Eggs ... ...	173,100	14·8	20	1·8	—	1·4
Milk ... ...	3,892,000	333·0	237	11·0	16·6	13·3
{ Butter ... ...	194,300	16·6	132	0·2	—	14·1
{ Margarine ...	173,200	14·8	115	0·2	—	12·3
Lard ... ...	91,300	7·8	69	0·2	—	7·3
Cheese ... ...	140,200	12·0	47	3·0	0·3	3·6
Potatoes ... ...	3,449,000	295·0	202	5·3	43	0·3
Peas, beans, and lentils ... ...	18,400	1·6	6	0·4	1	—
			1047	33	98	55

We see, then, that the foods available in 1916, other than meat, flour, and sugar, after subtracting a due share of them for the Army, leave per "man" a value of 1047 calories, with 33 grammes of protein.

The meat, flour, and sugar allowed gives 1746 calories and 70 grammes of protein. Adding the two together—that is, the "allowance" foods and estimated quantity of other chief foodstuffs available per man—we get a total of 2793 calories, 103 grammes protein, 357 g. carbohydrate, and 98 g. fat. There remain to be added tapioca, sago, arrow-root, fruit—all of some value, but not enough to alter the total materially.

The calculation allows no margin for loss in distribution or for waste.

It would, of course, be easy in ordinary circumstances to add other foods to the fixed quantities of meat, flour, and sugar so as to make up a diet of 3400 calories or more, and to ensure that it shall contain plenty of each needful food-stuff. But the problem before us is not the dieting of a few individuals or even of a large group; it is the feeding of the nation. It appears likely that if all the accessory food-stuffs could, apart from other considerations, such as cost, be divided equally among us, there would not be enough to make up the daily ration to 3400 calories per "man."

It is true that a large number of people eat much less than 3400 calories. For the majority of adults with sedentary occupations the allowance, plus such a share of the remaining foods as my estimate gives, is enough or more than enough. But there are others who need more than 3400 calories, and these others include the great mass of workers whose continued and efficient activity is essential at the present time. The food requirements of workers have been long established. A modern illustration of what ordinary workers consume will be found in the interesting Memorandum by Dr. Leonard Hill issued by the Ministry of Munitions.<sup>5</sup> A single meal frequently exceeds 1000 calories and may reach 1500, in net figures of the value of the meal as served, not as bought. Considerably more must be allowed for in buying the food. Further, men doing continuous severe labour may require well over 4000 calories. If the workers do not get enough food they cannot do the same work. A man may by grit or pluck work hard for a little while on a low ration, but he is living on himself and very soon his work will fail.

Meat and sugar are valuable foodstuffs, but their restriction does not matter so much as that of flour. More flour is needed, and every effort should be made, as no doubt it will

be made, to ensure the supply at the expense of any other commodity, for none other is so vital.

Probably the most valuable food to import, after wheat, is fat, such as margarine, on account of its high caloric yield per unit of weight. So long as our stock of cattle and sheep is not depleted,<sup>6</sup> sugar comes next from a dietetic point of view. In addition to being a useful food, with no waste, it has the great advantage of rendering other foods palatable. Cheese, again, until we make enough of it at home, is good food to import; it has a high energy value and there is but little waste in its use.

We hope for a more abundant and economical food production, such as we are told might be effected by adjusting crops, producing more milk, making more cheese, and the like; but changes in the conditions of agriculture and of labour take time.

It cannot be said that our people have suffered from any shortage of food so far. They will welcome the energy and earnestness with which the matter is being approached, and will await with much interest such measures as may be necessary to continue to ensure a sufficient and equal distribution of food.

## THE CONTROL OF VENEREAL DISEASES.

### *The Immediate Need of Compulsory Notification of Venereal Diseases for the Defence of the Realm.*

UNDER this heading a correspondent who signs himself "M.O." and who has undoubtedly given much time and thought to the question, writes to us as follows:—

I have recently had under my notice a case in which one woman, the wife of a soldier serving abroad, infected with syphilis three soldiers of the same battalion in the course of ten days. The police were communicated with, but are powerless in the matter unless the woman can be caught "soliciting," which, under the circumstances, is extremely unlikely—and there appears to be no remedy. At the present time compulsory notification is in force for men in the Army and Navy. All men suffering from venereal diseases are notified, sent to hospital, and kept there until cured. Surely there would be no injustice in extending the principle of notification and detention to women and to the rest of the population. But this notification should be limited to actively infective persons. No good would be done to compensate for the trouble involved in making syphilis in all stages compulsorily notifiable, but all women and men known to be a source of danger to the community and the State ought to be notified and sent to hospital until cured. This could be effected immediately under the Defence of the Realm Act.

We fully share our correspondent's desire to see immediate steps taken for the efficient treatment of all persons suffering from actively infective venereal diseases. The Royal Commission on Venereal Diseases also expressed this desire, and it is the working policy of the National Council for Combating Venereal Diseases which is helping to carry out the recommendations of the Commission. Our correspondent thinks that notification immediately put in force would help this policy. The Commission and Council thought otherwise, and have given reasoned arguments for their belief, which is shared by a large proportion of the active workers for venereal control. Put briefly, they hold that until skilled treatment is freely placed at the disposal of the venereal patient, and until he has been educated to believe in its value, compulsion will only drive him to concealment and the tender offices of the quack. But the quack will shortly be reduced to impotence, while the value of preventive measures is rapidly becoming better known.

### *The Remuneration of Female Medical Officers for Treatment Centres.*

At a meeting of representative medical women's societies held on Jan. 27th attention was drawn to the following facts: (1) That at least one advertisement, appearing in both the lay and medical press, for a female medical officer under a local scheme for the treatment of venereal diseases, offered a salary considerably lower than that offered to the male medical officer; and (2) that apparently the female medical officer was not to have charge of the female beds.

<sup>5</sup> Investigation of Workers' Food and Suggestions as to Dietary. L. E. Hill, M.B., F.R.S. H.M. Stationery Office. 1916.

<sup>6</sup> Agricultural Statistics, 1916, II., Part I., H.M. Stationery Office, 1917.

The following resolution was passed :—

That this meeting feels it to be a matter of urgent importance that, under any local venereal scheme, a medical woman should be appointed at an adequate salary, to have charge of the women's clinic and the women's venereal beds.

We have not seen the advertisement to which allusion is made, but we recall a passage in the city of Liverpool scheme in which it was proposed to offer a female non-resident clinical assistant a salary of £100, compared with £250 for the male assistant, "on the ground that the man's work will be more than double that of the woman's." Equal pay for equal service is a principle to which we believe the medical profession would generally assent.

#### *Treatment of Venereal Diseases in Honolulu.*

In the *Military Surgeon* for December last Captain L. C. Mudd, a member of the Medical Corps, U.S. Army, relates his methods for treating venereal disease in Honolulu. Gonorrhœa cases are kept in bed from the first, are given a four-hourly injection of 1 per cent. protargol into the anterior urethra, low diet, and a vaccine of gonococci—25 millions on the first day, the dose being repeated every other day and each time increased by 25 millions till 200 millions are reached. These injections are, the writer believes, useful in preventing or aborting the complications. In cases of syphilis he aims to attack the treponema as quickly as possible, and gives an injection of sa'varsan directly the diagnosis is clear (0·6 gm. suitably dissolved in 15 c.c. distilled water intravenously). Patients are not laid up, and no awkwardness has occurred. The injection is repeated weekly for three weeks more, and then 1 grain of salicylate of mercury is injected hypodermically over the ilium weekly for four weeks, when three weeks' rest is given. Subsequent treatment is regulated by the Wassermann reaction. This scheme of treatment has often prevented secondary eruptions, and during eight months no primary case so treated has been followed by roseola. A soldier who recently, in the first stage, refused treatment, was sent by court-martial to hard labour for six months. There has since been no trouble in securing the routine attendance of patients at the proper time.

#### *The London Hospital Medical College.*

Demonstrations on the methods of administering sa'varsan substitutes will be given in St. Anthony's ward of the hospital on Tuesdays at 1 o'clock.

#### *Enlightenment Campaign.*

In his public lecture on Social Prevention at the Picton Hall, Liverpool, on Jan. 26th, Professor J. M. Beattie said that Liverpool had not awaited the report of the Royal Commission to take action, but had for some time past through its health committee undertaken the investigation of venereal diseases in children. He expressed the opinion that the Commission's recommendations would not be crowned with full success until venereal diseases were made compulsorily notifiable.—Lord Sydenham, presiding on Jan. 31st at a lecture delivered before the Royal Institute of Public Health by Dr. O. J. Macalister on the Prevention and Arrest of Venereal Disease in Man, expressed the hope that legislation dealing with quacks and quack advertisements would soon be forthcoming, and also for the protection of the medical man from action for libel in connexion with information given in the public interest. Dr. Macalister said that he regarded education as the first weapon for use in the service of prevention and as a necessary preliminary to notification.

## THE SERVICES.

### ROYAL NAVAL MEDICAL SERVICE.

Fleet-Surg. E. B. Townsend is placed on the Retired List, with rank of Deputy Surgeon-General.

To be temporary Surgeons : H. M. Atkinson, A. A. Cockayne, D. G. Churcher, M. Pearson, W. V. Gabe, J. G. Stevens, C. J. L. Blair.

### ROYAL ARMY MEDICAL CORPS.

Capt. (temp. Major) J. Bruce to be temporary Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. R. A. Preston, Spec. Res., to be Lieutenant and to be granted the temporary rank of Captain.

Temp. Lieuts. John H. Thornley and R. O. Whyte to be temporary Captains.

Capt. W. L. Apilin Harrison, R.A.M.C., Spec. Res., to be Lieutenant, and is granted the rank of temporary Captain.

Temporary Captains relinquishing their commissions: A. G. Henderson, R. Sinclair, and G. Melville, T. S. Brodie, and R. M. Boyd (on account of ill-health).

Temp. Lieuts. Edward A. Seale and G. Kennedy relinquish their commissions.

### SPECIAL RESERVE OF OFFICERS.

Officers relinquishing their commissions: Capt. R. Hay, on appointment to Indian Medical Service, Capt. J. F. van der Westhuizen, Lieut. (on probation) C. R. Sandford (on account of ill-health).

To be Captains: Lieuts. J. Alston, J. J. B. Edmond, A. McM. Paterson, R. D. Cameron, W. J. F. Craig, W. L. Ingham, C. Rudd, M. Foster, J. Bennet, A. K. Gibson, B. J. Ryrie, J. M. Smellie, D. G. Stoute, J. A. C. Guy, C. W. Dudley, J. A. Nicholson, H. G. Broadbridge, W. Corner, R. R. Powell.

To be Lieutenants: N. S. Tirard, T. B. Micklem, R. A. Woodhouse, E. R. W. Gilmore (from University of London Contingent O.T.C.).

### TERRITORIAL FORCE.

Major A. H. Burgess is seconded whilst holding a temporary commission in the R.A.M.C.

To be Captain: Lieut. W. Rutherford.

Capt. L. D. B. Cogan to be acting Lieutenant-Colonel whilst commanding a field ambulance.

Capt. A. Cuffe resigns his commission on account of ill-health.

### DEATHS IN THE SERVICES.

Colonel Thomas Holbein Headley, C.I.E., I.M.S., on Feb. 2nd, at his residence, St. John's Wood, in his 70th year. He entered the Service in 1869, and was for 24 years Residency Surgeon at Jaipur, and for a few years Administrative Medical Officer for Rajputana. In 1897 he became Inspector-General of Civil Hospitals in the United Provinces, and subsequently, until his retirement in 1903, was the Permanent Inspector in Bengal.

### JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

In the January issue of this journal there appears the first instalment of the report of an Inquiry by Lieutenant-Colonel C. W. Wenyon and Captain F. W. O'Connor into some problems affecting the spread and incidence of intestinal protozoal infections of British troops and natives in Egypt, with special reference to the carrier question, diagnosis and treatment of amoebic dysentery, and an account of three new human intestinal protozoa. There is also a report by Captain Martin Flack on Cerebro-spinal Fever in the London District from December, 1915, to July, 1916, in which the author lays stress on the value of wide-wabbing on the appearance of the disease and the early elimination of carriers of the active organism. Captain R. V. Dolbey gives his experiences in the treatment of gunshot wounds involving the knee-joint, and Lieutenant-Colonel Alfred J. Hull his experiences in gunshot wounds of the spine, while Temporary Lieutenant E. D. Adrian contributes the beginning of a paper discussing the electrical reactions of muscles before and after nerve injury.

## URBAN VITAL STATISTICS.

(Week ended Feb. 3rd, 1917.)

*English and Welsh Towns.*—In the 96 English and Welsh towns, with an aggregate population estimated at nearly 18,000,000 persons, the annual rate of mortality was equal to 18·7, against 16·2 and 17·0 per 1000 in the two preceding weeks. In London, with a population of more than 4,000,000 persons, the death-rate was 19·8, or 1·4 per 1000 in excess of that recorded in the previous week; in the remaining towns the rate ranged from 11·4 in Hornsey, 11·7 in Dewsbury, and 11·9 in South Shields, to 29·1 in Bootle, 31·0 in Exeter, and 31·2 in Bath. The principal epidemic disease caused 265 deaths, which corresponded to an annual rate of 0·8 per 1000, and included 83 from infantile diarrhoea, 82 from measles, 62 from diphtheria, 23 from whooping-cough, 12 from scarlet fever, and 3 from enteric fever. With the exception of enteric fever, the deaths from each of these diseases were in excess of the average in the three preceding weeks; measles caused a death-rate of 1·1 in Plymouth and West Ham, 1·5 in East Ham, and 4·6 in Wimbledon. The 818 cases of scarlet fever and the 1430 cases of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 7 and 40 in excess of the numbers at the end of the preceding week. Of the 6198 deaths from all causes in the 96 towns, 225 resulted from violence. The causes of 72 of the total deaths were uncertified, of which 16 were registered in Birmingham, 10 in Liverpool, 6 in Manchester, and 5 in London.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death rate was equal to 17·7, against rates declining from 18·6 to 16·9 per 1000 in the six preceding weeks. The 364 deaths registered in Glasgow corresponded to an annual rate of 17·0, against 18·8 per 1000 in London, and included 10 from whooping-cough, 4 from measles, 3 each from diphtheria and infantile diarrhoea, and 1 from scarlet fever. The 103 deaths in Edinburgh were equal to an annual rate of 16·2 per 1000, and included 2 each from whooping-cough and diphtheria and 1 from infantile diarrhoea.

*Irish Towns.*—The 201 deaths registered in Dublin were equal to a rate of 26·3, or 3·6 per 1000 higher than that recorded in the previous week, and included 4 from measles, 2 from infantile diarrhoea, and 1 each from whooping cough and diphtheria. In Belfast the 196 deaths corresponded to an annual rate of 25·9, and included 3 from infantile diarrhoea and 2 each from measles and whooping-cough.

*BRISTOL EYE HOSPITAL.*—At the recent annual meeting of the Bristol Eye Hospital, the Lord Mayor (Dr Barclay Baron) presiding, the medical report was presented showing 456 in-patients and 9269 out-patients treated during 1916. There was an adverse balance of £487 on the year's financial statement. The committee recorded their gratitude for the readiness with which the honorary staff had carried on without a house surgeon.

## Correspondence.

*"Audi alteram partem."*

### SPIROCHÆTOSIS ICTERO-HÆMORRHAGICA.

*To the Editor of THE LANCET.*

SIR.—In a letter in your issue of Feb. 3rd Dr. A. F. Hurst suggests that the name spirochætal jaundice should be given to the disease hitherto called Weil's disease, including the various forms of epidemic jaundice which have occurred in the French war area and elsewhere. The name has been recently under the consideration of the subcommittee of the Royal College of Physicians of London engaged upon the Nomenclature of Diseases, now overdue.

May I point out that the name proposed by Dr. Hurst and by Sir Bertrand Dawson<sup>1</sup> is not distinctive. The jaundice of relapsing fever is a spirochætal jaundice, and the rare jaundice of secondary syphilis is obviously spirochætal also. In course of time it is quite conceivable that we may find other spirochætes troubling the liver or the blood in the same way.

What is the objection to the name spirochætosis icterohæmorrhagica? It is rather long, and that is all. It was used by the Japanese discoverers of the organisms, and hence it has a certain title to respect. It has been used by Captain A. Stokes and Captain J. A. Ryle in September in the *British Medical Journal* and in January in *THE LANCET*. The name spirochætosis is on the lines of the names of other diseases based on the organism, and is no longer nor more ugly than some others—e.g., trypanosomiasis, bilharziasis, leishmaniasis, aspergillosis. The name is adopted as an alternative to relapsing fever in one of the "Military Books published by Authority"—namely, "Memoranda on Some Medical Diseases in the Mediterranean War Area" (p. 104).

But, of course, syphilis is a spirochætosis; it might be called *S. luetica*. Relapsing fever wants a qualifying word when it is called spirochætosis; it might be *Oermeieri*. If there are national or patriotic objections, *recurrens* might be tried, unless it is objected that the much-discussed jaundice is also recurrent. *Frambezia* is a spirochætosis; it might be called *S. tropica*, only that *frambezia* is sufficiently distinctive.

Can any shorter qualifying word than icterohæmorrhagica be found? It might be *S. japonica* in reference to its discoverers, or *S. gallica*, if it be granted that the disease was first described by French authors. But, on the one hand, the French writers certainly did not find the spirochæte, and, on the other hand, the name would recall associations of the other spirochætosis which would not be desirable. As the paper recording the discovery of the spirochæte in March last is written by five Japanese authors, the qualification by means of the discoverers' names would be even more cumbersome than that which we have in spirochætosis icterohæmorrhagica.—I am, Sir, yours faithfully,

FRDERICK TAYLOR,  
Chairman of the Committee.

London, W., Feb. 5th, 1917.

### THE PHENOMENA OF ANAPHYLAXIS.

*To the Editor of THE LANCET.*

SIR.—In reply to several letters which have been addressed to you in connexion with my paper in your issue of Jan. 20th, may I point out that it should be read in the light of the first paragraph, where my object in writing it is distinctly defined. At the present time many practitioners are called upon to administer antitoxic sera, while they have no time to study the question of anaphylaxis nor, in many cases, the inclination to expend the energy necessary in wading through the voluminous literature of it. Their ideas, therefore, are necessarily somewhat hazy, and it appeared worth while to attempt to outline the subject as concisely and clearly as possible, and so to afford a basis on which they could work. I have in consequence been forced to confine myself to the general rule, neglecting to a great extent the exceptions thereto. That such exceptions are met with I think is clearly

<sup>1</sup> Quarterly Journal of Medicine, vol. x., Nos. 37 and 38, October-January, p. 50.

indicated in the paper itself, and in sending it to you I anticipated, apparently mistakenly, that the impossibility of living, within rigidly fixed limits, the quantities of antigen necessary in all circumstances to produce all or any of the phenomena of anaphylaxis was sufficiently emphasised. I am convinced, however, that my description represents the facts as accurately as is at present known, and indicates the way in which almost to eliminate the danger of anaphylaxis.

The object of the paper also rendered undesirable the inclusion of many of those details for which Dr. A. S. Leyton asks in his letter in your issue of Feb. 3rd. During the last three months I have seen over 200 serum-treated cases in this hospital alone with three slight cases of anaphylaxis. All these latter had previously received a total of 10 c.c. or more of serum, and in all a period of more than 14 days had elapsed between the ultimate and penultimate injections. Moreover, a series of injections at comparatively long intervals (7 to 10 days) has never caused hypersusceptibility; those cases that reacted had all received a series with short intervals (1 to 2 days). In no case in my series has sensitisation been effected by 3 c.c. or any amount remotely approaching it, although 3 c.c. has been a sufficient toxigenic dose. All of these cases I have carefully observed, and I hope at the termination of my present work to place the details of them on record.

For the figures given in my paper I make, and made, no claim to absolute accuracy, for that is not yet possible; the statement, however, that 4 to 5 c.c. of serum are required to form a toxigenic dose for a guinea-pig is in agreement with the finding of most workers, and the appearance of anaphylactic shock after 4 to 5 minims is certainly not common. Further, as regards the giving of antigen by the mouth, the statement that such ever produces anaphylaxis is explained by the first paragraph of this letter. The possibility of its very rarely doing so is a natural deduction from the previous statement that in certain conditions where the permeability of the walls of the alimentary canal is diminished unchanged antigen may be absorbed, and is, moreover, expressly noted in the footnote referring to the passage in question.

While, however, on the one hand I am so definite as to be obviously wrong, Dr. Frederic Thomson, on the other hand, in his letter in your issue of Jan. 27th (for which I thank him) finds me so indefinite as to be difficult to follow. From what has already been said it is evident that the question of the sensitisation of man is still involved in the greatest obscurity, and my want of precision in the definition of dosage is almost impossible to avoid in existing circumstances. I shall nevertheless venture to indicate by figures what roughly is implied by some of the terms used in my paper. Observation of experiments shows that if a number of animals be taken and each given a single injection of antigen, the second receiving more than the first, the third more than the second, and so on, no hard-and-fast line can be drawn between the effects produced by any two of the series; the intensity of such effects appears to form a curve rising from zero to a maximum, whence it falls again, probably never to zero, but always approaching that point. One is thus reduced to the necessity of a more or less arbitrary division into "small," "considerable," and "massive" doses. As stated in the article referred to, I consider anything below about 5 c.c. a small dose and as effecting no sensitisation, but what dose can be called considerable—i.e., sufficient to sensitise—cannot be so definitely stated and certainly varies in different individuals. I believe that from 15 to 30 c.c. fairly represents it. Anything over 50 c.c. will constitute a massive dose. Small doses, therefore, will have been received by those persons who have suffered one or two prophylactic injections (I speak here, of course, only from the point of view of tetanus); considerable doses by those having three to six, or perhaps ten; and massive by those who have had a larger number of prophylactic or one or more therapeutic doses. Where a number of injections has been given the size of any particular member of the series is of little consequence, the total quantity is the essential factor provided that each injection be made within 10 to 14 days of the preceding; and, of course, the amount of antibodies contained in the serum has no influence whatever on the production of anaphylaxis.

Referring to my statement that any person who has received one or more injections more than 14 days previously must be considered anaphylactic, the contradiction between

it and the above is apparent rather than real. I have never found one or two small doses sensitise a man, but that such a result *never* follows is more than I am prepared to affirm. Therefore, to be on the safe side it is recommended that such person be assumed to be hypersensitive.

I am afraid that I cannot give complete assent to Dr. Thomson's remarks concerning the rashes seen in serum disease, for my experience differs from his. I am at the time of writing completely separated from all my notes, so can give no figures as to the frequency with which I have observed the various eruptions, but a circinate rash has never come under my observation; the great majority have been urticarial with an extremely rare erythematous or morbilliform appearance.

Dr. M. B. Arnold's letter in your same issue is of great interest, and apparently the possibility of a laryngeal oedema should be borne in mind in human anaphylaxis. The details of the condition can, however, be worked out only by observation of anaphylaxis in man, for skin eruptions are not exhibited by laboratory animals. In any case it must be rare, for, so far as I am aware, no other such case has ever been recorded, and as a rule the symptoms point very definitely to an obstruction in the bronchioles and in no way suggest any lesion in the upper respiratory tract. I am of opinion that tracheotomy is not justifiable except in extremis.

With Dr. W. W. O. Topley I am in entire agreement when he says in his letter in your issue of Feb. 3rd that many cases occur which appear hard to reconcile with many of our present ideas concerning the mechanism of anaphylaxis, although I cannot see that his Case 1 offers any such difficulty. Such an experiment is essentially the same as that which forms the basis of Friedberger's theory of anaphylaxis—viz., that it is due to anaphylatoxin produced by the action of a specific antibody upon its antigen and the injection of anaphylatoxin engenders anaphylaxis without any preliminary sensitisation.

I further agree with Dr. Topley that there is evidence pointing to the fact that there is a cumulative element in the condition and have pointed out such possibility in answer to Dr. Thomson above (which was written several days before receipt of Dr. Topley's letter). But there would appear to be a difference between the condition brought about by a series of doses at short intervals and that of a sensitive person who has received a single subminimal injection; at any rate, such a difference is possible, for while the former may be due to a cumulative effect the latter cannot be so explained. As a matter of fact, it is known that in the immunisation of an animal the antigen may in some cases still be demonstrable unchanged in the blood some time after the last injection, but the amount gradually decreases and finally disappears. Thus in the case supposed of a single subminimal dose administered to a sensitive person no antigen is present in the body, and on receipt of the subminimal dose there is not sufficient anaphylatoxin liberated to produce symptoms, but a certain amount of antibody is fixed (negative phase) and complement as well; the animal is thus desensitised. In the case, however, of a continuous series of injections the quick succession of them more than possibly causes the persistence of antigen in the blood, until finally so much remains that on injection of even a small additional amount anaphylatoxin is produced in such quantity as to become manifest by symptoms. All such ideas are, of course, highly theoretical, but serve to show that the two conditions may be, and in my opinion probably are, quite different. A wholly satisfactory theory is as yet far from being demonstrated, and it appears likely that it will remain so until the principles of physical chemistry have been much further elucidated and have found a wider application to biological problems.

I am, Sir, yours faithfully,

Port Pitt, Chatham, Feb. 3rd, 1917. S. WYARD.

#### PNEUMATIC TOURNIQUETS.

To the Editor of THE LANCET.

SIR.—I was pleased to read in your issue of Jan. 27th the appeal of my friend, Professor K. H. Digby, for the more general use of pneumatic tourniquets. From a surgical point of view such a tourniquet must be admirable. My own use of the sphygmomanometer as a tourniquet is for venepuncture for any purpose. In neurological work it is useful

most commonly for the intravenous injection of "606" and "914," but it is adapted equally well for the withdrawal of venous blood. The armlet is readily applied and the air can be pumped into it until the radial pulse is just not obliterated. In this way the maximum obstruction to the venous circulation is effected, without abolition of the arterial flow. When the puncture has been made the armlet can be deflated without causing the slightest movement of the patient's arm.

For several years I have used the portable sphygmomanometer known as the "Tyco" with very satisfactory results.

I am, Sir, yours faithfully,  
HILDRID CARLILL, M.A., M.D. Cantab., M.R.C.P. Lond.,  
Feb. 1st, 1917. Neurologist to the Royal Naval Hospital, Haslar.

#### LEAKAGE OF "NEURO-ELECTRICITY" AS A CAUSE OF TRENCH FOOT.

To the Editor of THE LANCET.

SIR.—In your issue of Jan. 13th Lieutenant C. Nepean Longridge quotes experiments which he has made with a view to showing that the condition known as "trench foot" is brought about by an undue leakage of some form of natural electrical energy from the extremities. Assuming his observations to be correct, they no doubt do show that a loss of what has been provisionally called neuro-electricity takes place under the conditions which obtain, or used to obtain, at the front during winter. They do not in themselves prove, however, that such loss is the cause of the pathological changes which occur. Neither, however, does the immunity of coolies in rice-fields disprove the theory. Heat regulation in warm-blooded animals is a complex process, for the proper working of which the integrity of the nervous system is, among other things, necessary. If this heat-regulating mechanism be artificially interfered with the animal experimented on quickly dies—unless means are taken to keep up its body heat by regulation of the external temperature. In the case of the coolie the temperature of the water is nothing like so low as it is on the Western front in the winter. Moreover, the coolie is inured to the work from childhood, and the adaptive power of the nervous system is well known.

It may be accepted that "loss of neuro-electricity" is not the direct cause of trench foot; but that the loss, if it occurs, interferes with the local nervous mechanism for heat regulation is not improbable. It is a well-known fact that limbs with a damaged nerve-supply due to gunshot injury become blue, congealed, and even ulcerated if exposed to a degree of cold which would not affect them normally; whereas in really warm weather—or even for a short time after a hot bath—their appearance is natural. Low external temperature, in short, does not affect a limb injuriously so long as the heat-regulating mechanism is capable of maintaining the normal internal temperature. But the balance may be adversely disturbed either (a) by a degree of external cold sufficient to overcome the normal arrangements—e.g., frost-bite; or (b) by a less degree of cold acting upon an enfeebled mechanism. Oiling the feet is certainly of value. It does not appreciably "keep the cold out," but may conceivably "keep electricity in." The success of such a measure is therefore a point in favour of Lieutenant Longridge's hypothesis.

I am, Sir, yours faithfully,

FRANCIS HERMAN-JOHNSON.

Cavendish-square, W., Jan. 30th, 1917.

#### THE GLYCOSURIA ASSOCIATED WITH MENINGITIS.

To the Editor of THE LANCET.

SIR.—The case of suppurative meningitis with coma and glycosuria reported in THE LANCET of Feb. 3rd by Dr. F. E. Taylor and Captain W. H. McKinstry render the following observations of interest. In two cases of epidemic cerebro-spinal meningitis recently under our care in the London Fever Hospital we took the opportunity to examine the urines and the cerebro-spinal fluids for glucose from the onset of the disease. We found that during the first three days the urine contained small amounts of glucose, but that this substance was completely absent from the cerebro-spinal fluid. After the third day, when the acute invasive

symptoms were subsiding, the reverse was the case. The osazones were prepared from these fluids and were characteristic of glucose. Both cases proved fatal. In a third case recently under the care of one of us, temporary glycosuria was present in the early stages of a relapse. This relapse terminated in hydrocephalus and also proved fatal.

Some time ago Dr. Archibald Garrod drew attention to the fact that glycosuria was not infrequent in the terminal stages of tuberculous meningitis. Our cases were all meningococcal and the glycosuria, instead of being terminal was initial and transitory. In this respect they correspond more closely with the case of suppurative meningitis reported in your columns, and it seems unfortunate that in this the cerebrospinal fluid was not bacteriologically examined during life.

Our cases are too few for us to attempt to base any evil prognostic importance on this early glycosuria in cerebrospinal meningitis. As regards the occurrence of acetonuria this is so common in acute specific fevers where the constitutional disturbance is of any severity that it is deprived of any special significance.

We are, Sir, yours faithfully,

CHARLES R. BOX,

THOMAS G. NICHOLSON.

### THE ABNORMAL SIZES OF OFFICIAL PUBLICATIONS.

To the Editor of THE LANCET.

SIR.—The Stationery Department of the War Office from time to time issue pamphlets for the guidance of medical officers. I would like, through the courtesy of your columns, to make the following suggestions for future issue of these pamphlets.

They should be of a uniform size, with a margin for notes; perhaps, on the whole, "quarto" size would be the best form, failing that "octavo" size. I have on my desk at the present moment pamphlets varying in size from foolscap to booklet ( $5\frac{1}{2} \times 4$ ). As most of these pamphlets are of considerable value in helping the medical officer to be up to date, it is desirable they should be so "made up" that they could be bound together and form a standard work of reference. At the present time it is found that they are read, perhaps only glanced at, and put away—not to be found when wanted. This I attribute in part to the "make up," which does not lend itself to any standard system of filing or binding.

I am, Sir, yours faithfully,

Jan. 30th, 1917.

#### MED. SERVICES.

\* \* We sympathise whole-heartedly with our correspondent. The War Office publications only offend in the same way as all official publications. The sizes and shapes of the Reports of Medical Officers of Health and of the authoritative documents from all the great departments are bewilderingly varied, making comparative reference and convenient housing impossible.—ED. L.

### THE PRE-WAR MEDICAL OFFICER (S.R.) AND (T.).

To the Editor of THE LANCET.

SIR.—May I through the medium of THE LANCET draw attention to the following points?

1. (a) The consolidated rate of pay of the new-joined temporary officer R.A.M.C. is approximately equal to the total pay and allowances of the Special Reserve and Territorial Captain. The former is either new-qualified or has had opportunities to minimise his losses; the latter has in many cases, if he was called up on mobilisation, to support wife and family solely upon his pay and allowances. The rise in the cost of necessaries at home presses hard upon families now. (b) The Special Reserve officer who joined in the early days of its formation received £20 kit allowance on joining. The war has now lasted two and a half years. The cost of kit has risen. The medical officer who has served with an infantry regiment in winter trenches on the Somme offensive has got through much clothing since the war began! (c) The Special Reserve or Territorial officer if wounded loses the greater part of his allowances; the "temporary" maintains his consolidated rate of pay. (d) The "temporary" is entitled to a fortnight's leave on the renewal of his contract without prejudice to his consolidated pay. The Special Reserve or

Territorial officer gets but his 8 or 10 days' leave, and is liable to deduction of allowances.

2. The following suggestions are made:—(a) Any Special Reserve or Territorial officer, R.A.M.C., who has not less than two years' active service abroad, shall, upon completion of six years' service, commence to draw the pay and allowances of a Captain, R.A.M.C., of seven years' service. (b) Any Special Reserve or Territorial officer with not less than two years' active service abroad, of which not less than one year has been with an infantry regiment in the line, shall be eligible for a kit gratuity equal to the difference between the amount of his kit allowance on joining and £50. (c) Any Special Reserve or Territorial officer shall draw his full pay and allowances during such time as he is unfit for duty by reason of wounds received in action. All the above to be retrospective.

3. It is submitted: (a) that the principal cases of hardship would be alleviated; (b) that the number of such cases is sufficiently small to render the charge upon the public not great enough to militate against the adoption of the above suggestions.—I am, Sir, yours faithfully,

Jan. 26th, 1917.

IN ARDUIS.

### Obituary.

HENRY HUMPHREYS, M.A., M.D. CANTAB.,  
M.R.C.P. LOND.

Henry Humphreys, who died at Richmond on Jan. 16th at the age of 72, was a man of brilliant talents, who, had it not been for his weak health, might well have attained great distinction. He was the son of Mr. Charles Humphreys, an architect. Educated at the City of London School. Henry Humphreys proceeded to St. John's College, Cambridge, where he graduated as Fifth Wrangler, proceeded to the M.A. degree in 1870, and became a Fellow of his college. He studied medicine at University College, London, qualified in 1872, took his M.D. in 1875, and the M.R.C.P. in 1877. In 1873 he joined the Middlesex Hospital, where, after holding the posts of house physician and obstetric house physician, he was appointed medical registrar, and prepared the interesting and carefully compiled reports for 1875 and 1876. In 1877 he married a daughter of Dr. E. Duncan, and in the same year went to reside at Manchester, having been appointed physician to the Pendlebury Hospital for Sick Children. He threw himself *con amore* into his new duties, and had already given promise of good scientific work, when, under unforeseen trials, his health broke down, and he was compelled to resign office after three years' tenure and abandon a career for which he was eminently fitted. For the next ten years he practised as a physician at St. Leonards, where he was attached to the hospital, and after that for five years at Fleet, and finally at Torquay, whither he removed in 1888. Here for another decade he spent a quiet and industrious life, not overburdened with practice, and taking much interest in the Natural History Society and Museum, of which he was president. His last work was to prepare an elaborate study of mosses for a meeting at Launceston, where the first symptoms of another breakdown occurred, which necessitated his retirement from active work, and from which he never entirely recovered. For nine years he was devotedly tended by his wife. He died after a few days' illness from heart failure.

Dr. Humphreys was a man of fine character, modest and retiring, and thoroughly unselfish. During his hospital life he proved to be a shrewd observer, keen and enthusiastic in the pursuit of clinical medicine. It was a disappointment to his London friends, as it must have been to himself, that his career at Manchester was so abruptly cut short from no fault of his own.

AN important informal conference between representatives of various Government departments and public bodies was recently held under the chairmanship of Lord Balfour of Burleigh, when a proposal by the medical adviser to the Insurance Committee for the County of London for a national scheme for the after-care and employment of tuberculous persons was discussed. A small committee was nominated to consider what further action should be taken in the matter.

# The War.

## THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue :—

### Died.

Capt. B. D. Gibson, Australian Light Horse, who was acting as a combatant officer, qualified in Ireland in 1904, and had held public appointments in Dublin and in Cape Colony.

### Wounded.

Capt. C. H. Lilley, R.A.M.C.  
Lieut. Balkrishna, I.M.S.

## DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war :—

Major J. E. Moir, Indian Cavalry Staff, Cavalry Brigade, youngest son of the late Dr. Moir, of St. Andrews, N.B. Second Lieut. E. E. Brannigan, West Yorks Regiment, son of Major J. H. Brannigan, R.A.M.C., of County Mayo, Ireland.

Transport Officer J. E. McElpatrick, only son of Dr. J. McElpatrick, of Alderley Edge, Cheshire.

Capt. M. G. Donahoo, M.C., King's Own Yorkshire Light Infantry, only son of the late Dr. T. M. Donahoo.

Lieut. R. J. Graves, Royal Irish Rifles, elder son of the late R. W. Graves, F.R.C.S., J.P., of Gloucester.

## OBITUARY OF THE WAR.

### CHARLES EDWARD RECKITT, L.M.S.S.A. LOND., SURGEON, ROYAL NAVY.

Surgeon C. E. Reckitt, who died on Jan. 20th as a result of illness contracted on active service, was 30 years of age and the elder son of Lieutenant-Colonel J. D. T. Reckitt, R.A.M.C. He was born at Bellary, India, educated at Bedford Grammar School and Berkhamsted School, entering at Guy's Hospital for his medical study in 1905. Qualifying in 1913, he was assistant house surgeon at his own hospital and held the post of ophthalmic house surgeon at the Hull Royal Infirmary. In April, 1915, he joined the Royal Navy, leaving Haslar a month later on his appointment to H.M.S. *Shannon*. He was senior surgeon on this boat when,

at the beginning of December last, he developed cellulitis of the forehead. After several operations osteomyelitis of the frontal bone was succeeded by a subdural abscess and he was transferred to Haslar Hospital where he died. Surgeon Reckitt's personal qualities are well described by a hospital intimate : "I first came across Surgeon Reckitt," he writes, "in the swimming-bath, where I was struck by his neat, well-knit figure and his good diving, which won many prizes

at the 'Guys' water sports. Later on he was dresser to Mr. Philip Turner and a member of Sir Alfred Fripp's firm. To us he was always 'Charles'; no surname seemed to be necessary, for he was the life and soul of any firm he was on. Quick and alert, merry and jovial through the longest night's work, he seemed tireless and full of energy in the small hours when no one is supposed to be a hero. With his patients he was painstaking and careful, but he added to his treatment a kindly word and a most infectious smile that will make him remembered for many a day."

Surgeon Reckitt married in July last Madeleine Violet, younger daughter of Mr. de Quetteville, of Jersey.

### FRANK ERNEST ROCK, M.D. LOND., D.P.H., SURGEON, ROYAL NAVY.

Surgeon F. E. Rock was one of two Naval surgeons aboard H.M.S. *Laurentic*, which went down off the Irish coast on Jan. 25th. After a brief career as a student at Middlesex Hospital, from which, in 1893, he graduated with honours in medicine and obstetric medicine at London University, taking his doctorate in the following year, Dr. Rock was for a time assistant medical officer at Huddersfield, leaving in 1908 to organise the medical work amongst the 14,000 children in the public elementary schools of Edmonton, where, four years later, he became assistant medical officer of health and assistant school medical officer. In his early days, after a period of private practice in Hammersmith, he had served in the Royal Navy, and as a member of the Special Reserve of Officers was called up when the British Fleet was mobilised in July, 1914, and again for active service the following month. He worked hard, at first at Chatham Naval Hospital, later on board H.M.S. *Wallaroo*, before joining H.M.S. *Laurentic*, on which he lost his life, his colleague, Surgeon W. P. Starforth, being rescued. A colleague of Surgeon Rock's writes of him : "His modest bearing and unassuming manner made him a host of friends wherever he went, and by all of these his death will be deeply regretted."

### PERCY ARNOLD LLOYD-JONES, B.A., M.B., B.C. CAMB., D.S.O., MAJOR, ROYAL ARMY MEDICAL CORPS.

Major P. A. Lloyd-Jones, who was killed in action in France on Dec. 22nd last at the age of 40 years, was son of Mr. E. Lloyd-Jones, of Abbotshill, Great Malvern, formerly of Sale. Educated at Manchester Grammar School, he graduated at Cambridge in 1898, going on to St. Bartholomew's Hospital for his clinical studies, qualifying M.R.C.S. & L.R.C.P. Lond. in 1904. After a house appointment at Bedford County Hospital he entered the Royal Army Medical Corps at once, becoming Captain in 1908 and Major in 1915. He had seen a variety of service, as he volunteered as a private in the Yeomanry during the South African War, being awarded the Queen's medal with three clasps and entering Pretoria with Lord Roberts. On his return he was made honorary member of the borough of Cambridge. Later, when stationed at Malta, he rendered assistance at the Messina earthquake and was decorated with the Red Cross medal and the Order of the Crown of Italy. He went over to France in the early days of the present war, was appointed to the command of a field ambulance with the temporary rank of Lieutenant-Colonel, and became Deputy Assistant Director of Medical Services. He was twice mentioned in despatches and received the D.S.O. in June last. His death was due to a chance shell which hit him when busied with work just behind the firing line.

Major Lloyd-Jones is described by his commanding officer as an exceptionally brilliant staff officer and an honourable, upright, and hard-working official. His life

record shows a remarkable range of activities at home and abroad, while letters which we have seen speak of his sense of duty and love of home and children. A wide circle of friends will mourn their loss.

#### THE HONOURS LIST.

The following promotions of and awards to medical officers are announced:—

C.B.

Col. (temp. Surg.-Gen.) G. D. Hunter, C.M.G., D.S.O., A.M.S.; Lt.-Col. P. B. Haig, I.M.S.

D.S.O.

Maj. (temp. Lt.-Col.) W. Benson, R.A.M.C.; Lt.-Col. (temp. Col.) F. B. Gunter, R.A.M.C.; Lt.-Col. (temp. Col.) C. A. Johnston, C.I.W., I.M.S.; Capt. G. J. Keane, R.A.M.C.; Lt.-Col. (temp. Col.) G. W. Tate, R.A.M.C.; Lt.-Col. R. F. Turner, I.M.S.; Lt.-Col. H. A. Moffat, S. Afr. Med. Corps; Temp Lt.-Col. C. H. Muller, S. Afr. Med. Corps; Lt.-Col. W. B. Skinner, S. Afr. Med. Corps; Lt.-Col. J. H. Whitehead, S. Afr. Med. Corps.

*Military Cross.*

Capt. R. S. Kennedy, I.M.S.; Capt. C. V. Thornton, R.A.M.C.; Capt. H. Payne, S. Afr. Med. Corps.

#### MENTIONED IN DESPATCHES.

The *London Gazette* publishes a lengthy list of additions to and corrections in the names of those mentioned in recent despatches, and the following affects the lists published in THE LANCET:—

*Mesopotamia* (THE LANCET, July 8th, 1916, p. 79).—Add the name of Major W. C. Croly, R.A.M.C.

*Mediterranean* (THE LANCET, July 22nd, 1916, p. 163).—Under the heading of "Royal Army Medical Co-op." for Major W. Jones read Major W. W. Jones (T.F.); for Capt. R. Hobson read Capt. R. Hobson (T.F.).

*British Army in France* (THE LANCET, Jan. 13th, p. 83).—Under the heading of "Canadian Army Medical Corps," delete the name of Major E. H. Baylock (not a medical officer).

#### THE MOBILISATION OF THE MEDICAL PROFESSION.

Mr. Neville Chamberlain, the Director-General of National Service, made on Tuesday last a statement as to the direction in which his plans might be expected to mature so as to obtain from the general population services of all kinds. In the course of his address he said:—

There are two classes which stand apart from the rest of the community, because their services are required in particular directions. I refer to doctors and ministers of religion. So far as the clergy of the Church of England are concerned, I have been in communication with the Archbishops, and we have formulated plans which I hope will enable many clergy to give effect to what I know to be their desire, and to offer themselves for national service other than that connected with their parishes. They will be put to do work of a special character, perhaps in different parts of the country. As to doctors, I have been in touch with the General Medical Council, and, although my plans are not yet completed, I hope it will be possible for me to arrange something for them on analogous lines. We have to see that the doctors are so mobilised and distributed that the needs of both the civil population and the Army can be met, and that, so far as possible, specialists can be put to do the work for which they have taken pains to fit themselves. With those exceptions, I am going to appeal to the whole male population of this country between the ages of 18 and 61.

Readers of THE LANCET will not be surprised at learning the decision of the Director-General of National Service to treat the medical profession as one whose utility to the nation is so special along definite lines that any attempt to use its personnel outside medical lines must be bad economy. On the other hand, the life of the medical practitioner is necessarily so intimately bound up with the fortunes of those among whom he lives that mobilisation of the medical profession, in the strict sense of the word, must be far more difficult for all concerned than it would be in connexion with any other occupation.

The Director-General of National Service will find the medical profession considerably prepared for the economising of man power and the distribution of work which he proposes to bring about. The Central Medical War Committee has since its foundation been impressed with the necessity, while discharging its primary duty of finding officers for the military and naval services, of arranging that the medical practice of the country, both in public departments and in individual undertakings, shall proceed with due efficiency and with the minimum of inconvenience or distress to the public. The Central Committee in a communication

to the Local Medical War Committees (now being issued) asks those Committees to submit the names of all men of military service age in their areas, pointing out that a great strain must shortly fall on the remaining members of the medical profession, and that medical services will have to be cut down to the really essential basis. The military authorities have a legal claim on the services of every man of not more than 41 years of age at the dates appointed by the Military Service Acts, and the Central Medical War Committee indicates that the public must be prepared to do with less medical attendance, just as they are having to acquiesce in many other forms of shortage.

It is understood that the Insurance Commissioners are informing the Insurance Committees throughout the country that they must be prepared to deal promptly and effectively with the demands that will be made upon them for the release of all practitioners under contract with them who can be spared, and the co-operation of the National Insurance Commission with the Central Medical War Committee has been throughout of an encouraging and remarkably efficient character. The Central Medical War Committee is advising the Local Medical War Committees that in every area the action of local authorities with regard to the medical men under contract must depend on the extent to which the local profession can show hearty co-operation. The authorities have the duty of providing certain medical services, and are expected to pay the practitioners under contract with them during their absence on military service; but these emoluments cannot be continued unless the work is carried out by someone. Fully recognising this, the Central Medical War Committee is suggesting to the Local Medical War Committees the methods by which the manpower of each area can be minimised, while satisfying the local authorities in their legitimate demands. The institution of co-operative central arrangements is proposed, whereby patients may attend at central surgeries, or whereby groups of doctors may undertake in common the attendance of all patients in one particular area, and it is to be hoped that the public will be ready to fall in with all such plans. The public support will certainly be given more readily by as much as those who work the local practices as substitutes are able to do so from those premises where the medical services had been previously rendered. It is obvious that much can be done to lessen night and emergency calls by an arrangement whereby one or two men in an area should be on duty on certain nights or at certain times.

The Central Medical War Committee goes, in its suggestions, further than anything which Mr. Neville Chamberlain was able at the time to say in public, for every medical practitioner who is capable of doing any medical work at all is considered by the Committee to be liable to be called upon to do what lies in his power.

#### THE ARTIST AT THE FRONT.

The second instalment of the *Western Front*, which is published under the authority of the War Office by "Country Life," Limited, and George Newnes, Limited, contains 20 further illustrations by Mr. Muirhead Bone, and it is our impression that the scenes in this issue may make a more popular appeal than those which appeared in the first instalment. The special qualities of the artist are wonderfully exemplified in such pictures as No. 29, "British Troops on the March to the Somme"; No. 32, "Wrecked Aeroplane near Albert"; and No. 34, "Watching our Artillery Fire on Trones Wood." This picture, drawn from Montauban, most graphically depicts a battlefield where artillery fire has been heavy, craters being massed together as the result of high-explosive shells following with great frequency. Little imagination is necessary to realise how, at a later stage in bombardment, these craters, like pits in confluent small-pox, overlap, making the shell-lodged ground become soft and loose; the illustration really, if remotely, indicates some of the difficulties with which our troops have to contend. "A View Outside Arras," No. 38, could only have been drawn by an artist with real feeling as well as dexterity, and none save those quite unfamiliar with the real objects of the black-and-white draughtsman will be betrayed into thinking that its slapdash execution shows any lack of care or design. In No. 24, "Taking the Wounded on Board," Mr. Muirhead Bone gives us an example of his well-known skill in the drawing of buildings; and

this is more definitely displayed in 21, "A View of Amiens Cathedral," a wonderfully elegant and airy presentation, with aeroplanes flitting round the *flèches*, and in 37, "A Gateway at Arras," a vigorous piece of impressionism. An exhibition of the original drawings has now been opened at the galleries of Messrs. Colnaghi and Obach, 144, New Bond-street, W.; it is held on behalf of public funds for the prosecution of the war.

## AUXILIARY R.A.M.C. FUNDS.

Lieutenant-Colonel F. W. H. Davie-Harris, R.A.M.C., secretary of the Auxiliary R.A.M.C. Funds, 124, Victoria-street, S.W., sends us the following statement and encloses a list of donations received for the year 1916 for the Officers' Benevolent Branch of the above funds:—

The committee of the above funds are now prepared to receive and consider applications for assistance from the guardians of orphans in straitened circumstances of officers of the Auxiliary R.A.M.C. (the Special Reserve, Territorial Force, and the New Armies) who are eligible, their fathers having been killed in action, died of wounds or disease contracted in the service, or have held their commissions in the Auxiliary R.A.M.C. during the present war.

The object of the Officers' Benevolent Branch is to afford relief to those orphans of commissioned officers who may be left under circumstances of peculiar distress or who may be enabled by a small addition to their incomes, at a certain period of their lives, to procure a better education than their limited means would otherwise admit.

As the committee expect to receive a large number of applications, it is hoped that all those officers who have not yet become subscribers will kindly do so and so help, with timely assistance, to give a start in life to the orphans of their brother officers.

*List of Donations received for the Officers' Benevolent Branch of the Auxiliary R.A.M.C. Fund during the Year 1916.*

(Donors of £15 1s. become Life Members under Rule 11.)

## THE DIRECTOR-GENERAL OF THE ARMY MEDICAL SERVICE AND THE ARMY COUNCIL.

Lord Esher, in a letter to the *Times*, has warmly advocated inclusion in the Army Council of the Director-General of the Army Medical Service, and this would be a step which all medical men would recognise to be in the right direction. No one wishes to encumber the Army Council with too many representatives, but the progress of this war has shown us over and over again that it is difficult for a military officer to perceive the difficulties which must arise in a specialised and technical department. Yet unless the difficulties are perceived the remedies cannot be arrived at. The bestowal by the King on Sir Alfred Keogh of the high distinction of the Grand Cross of the Bath is a public acknowledgment of the way in which the Royal Army Medical Corps, supported from the outset by the efforts of the medical profession as a whole, has discharged its onerous work, and Lord Esher's appeal to the Secretary of State for War further to recognise this work by admitting the Director-General of the Army Medical Service to the Army Council is a very just piece of argument.

**HOSPITAL MAGAZINES.**—Everyone would rejoice if Lieutenant-Colonel Fayerre, the Commanding Officer of the 2nd Scottish General Hospital, should prove prophetic in his foreword to the February issue of the *Craigleath Hospital Chronicle* (Edinburgh, price 6d.), for he believes that it will be the last foreword he will be asked to contribute. The contents of the paper are of the creditable standard of its predecessors.—The February issue of the *Gazette of the 3rd London General Hospital* (Wandsworth, price 3d.) announces the return of Lieutenant-Colonel Bruce-Porter, C.M.G., as officer commanding. Lieutenant-Colonel Sir Alfred Pearce Gould, K.C.V.O., having filled the post in his absence. Most of the contents of this issue relate to the Christmas festivities, the illustrations being excellent.—We have also received No. 2, Vol. I., of the 5th, the magazine of the General Hospital

bearing that number (price 3d.). It is a satisfactory production, modelled somewhat on the style of the *Gazette of the 3rd London General Hospital*. In the article entitled "In Defence of the R.A.M.C." the author points out that the Corps has its full quota of heroes who have earned distinction for deeds of self-sacrificing devotion—a thesis which no one will deny.

**HEADQUARTERS** Southern Command have accepted the services of Mr. John R. Rolston as honorary consulting ophthalmic surgeon to the Plymouth garrison.

**THE ST. DUNSTAN'S HOSTEL** for blinded sailors and soldiers has benefited to the extent of £5000 devoted by Messrs. Kidder, Peabody, and Co., of New York and Boston, for the relief of sufferers from the war.

**RELATIVES** visiting sick and wounded sailors and soldiers have been granted the concession of single fare at the old rate for the double journey on the production of the hospital authorisation.

**ULSTER VOLUNTEER FORCE HOSPITAL.**—On Feb. 2nd the Duchess of Abercorn opened a new wing in connexion with the Ulster Volunteer Force Hospital, Belfast, which is to be devoted to the care of limbless patients and those needing special joint treatment. Mr. A. B. Mitchell has been appointed to take charge of the patients by the War Office, with the rank of temporary Lieutenant-Colonel.

## Medical News.

**EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.**—As the result of the Final Examination held from Jan. 9th to 24th the following candidates were approved in the undermentioned subjects, but are not yet eligible for the diplomas:

**Medicine.**—G. Adler, London; H. D. Apergis, Guy's; D. N. Baan, Calcutta and University College; H. E. Bickerton, Cambridge and Liverpool; A. H. Bon, Northwestern University, Chicago; Marian Noel Bostock, St. George's and Royal Free; J. B. Brash, Cambridge and St. Bartholomew's; I. Braun, St. Bartholomew's; C. J. Chesterman, Bristol; H. J. C. Churchill, St. Bartholomew's; A. M. Clement, St. Thomas's; J. C. Collins, London; W. T. Cooper, Charing Cross; R. S. Corbett, Cambridge and St. Bartholomew's; G. R. Cowie, Oxford and Middlesex; W. L. Dandridge and S. R. E. Davies, Cambridge and St. Bartholomew's; W. A. Drake, Leeds and St. Bartholomew's; F. S. Etholm, Bow in University; J. H. Ewen, St. Mary's; J. Fairbairn, Cambridge and London; H. Gainsborough, Cambridge and St. George's; M. W. Geffen, University College; G. H. Gladwin-Jackson, Cambridge and London; R. H. Glenny, St. Bartholomew's; E. F. S. Gordon, Cambridge and St. Bartholomew's; J. W. H. Grice, Guy's; H. O. Gunewardene, King's College; D. V. Halstead, Guy's; Joan Hardy, Royal Free; E. B. Hartley, Cambridge and St. Thomas's; K. K. Hill, University College; H. W. H. Holmes, Cambridge and St. Thomas's; J. C. C. Howe, Guy's; J. W. D. Hyde, University College; Loiza Johnston, American Medical Missionary College; J. I. Kubine, Charing Cross; H. W. Lewis, Middlesex; E. E. Llewelyn, Cambridge and St. Bartholomew's; L. G. Lunnon, Middlesex; B. Maclean, University College; N. H. S. Macler, Guy's; W. H. Mawling, University College; E. C. Moore, Liverpool and St. Thomas's; C. K. Mowll, London; C. P. Nagamuttu, Ceylon and Middlesex; T. M. Payne, Cardiff and St. Bartholomew's; A. H. Peart, Cambridge and St. Thomas's; A. M. Pickup, Birmingham and University College; C. V. Pink, St. Thomas's; W. L. F. Powell, London; H. N. Pritchett, Guy's; H. E. Rhodes, Cambridge and London; A. Rose-Innes, University College; A. H. Savory, St. Bartholomew's; J. J. A. Scott, Birmingham; R. Sims, London; E. D. Speckman, Cambridge and St. Bartholomew's; M. B. R. Swann, Cambridge and King's College; J. F. Twort, London; W. J. Walters, Cambridge and Guy's; P. Ward, Sheffield; F. E. G. Watson, St. Bartholomew's; H. G. Watters, London; W. J. White, St. Thomas's; and J. H. Wissman, A. F. Wyatt, and S. Yahilevitz, London.

**Midwifery.**—A. L. Abel, University College; H. C. Apperly, Middlesex; H. W. Archer Hall, Birmingham; H. S. Baker, St. Bartholomew's; Ruth Balfour, Royal Free; Althea Josephine Bolton, Birmingham; Marian Noel Bostock, St. George's and Royal Free; E. W. Bowell, Guy's; I. Braun, St. Bartholomew's; A. G. Brett, Liverpool; H. B. Bulen, Cambridge and St. Bartholomew's; G. T. Calthrop, Cambridge and London; D. Cameron, St. Bartholomew's; H. Carpenter, University College; B. R. Chaulk, St. Mary's; A. B. Cocker, Guy's; J. C. Collins and G. W. Combe, London; C. G. Coombs, Guy's; A. J. Copland and R. Cyte, St. Bartholomew's; C. Depta, Louvain and University College; H. L. Douglas and W. Kidman, London; M. Erzin, Cirencester; S. Finkelstein, Charing Cross; J. W. H. Gee, Guy's; Grace Mary Giulson, Griffith, Cardiff and Leeds; F. Herrington, Guy's; F. J. Harvey, Birmingham; F. Y. Hasaballa, St. Thomas's; C. B. Henry, Westminster; L. G. Higgins, Cambridge and St. Thomas's; T. C. Higgins, St. Bartholomew's; S. L. Higgs, Cambridge and St. Bartholomew's; J. Hollings, London; G. R. Hubbard, Guy's; Loiza Johnston, American Medical Missionary College; D. M. Jones, London; S. Kadinsky, Brussels and Westminster; J. G.

Lawn, Cambridge and St. Thomas's; H. W. Leathem, Cambridge and St. Thomas's; L. K. Ledger, St. Bartholomew's; A. W. Lewis, St. Mary's; D. J. A. Lewis, London; Marguerite Frances Jane Lowenstein, Royal Free; G. E. MacAlvey, St. Mary's; P. D. J. Milnans, Middlesex; R. S. Millar and J. O. R. Montonchon, Guy's; A. Moore, Manchester and Birmingham; C. K. Mowll, London; Annie Shortridge Miles, Royal Free; W. W. Newton, Birmingham; W. D. Nicol, St. Bartholomew's; J. M. Parry, Charing Cross; H. T. Pryce-Jones, Cardiff and St. Mary's; R. E. Rampling, St. Thomas's; P. Randall, Cardiff and St. Mary's; Gwenola Mary Reille and Sarah Sophie Rosenberg, Royal Free; J. Rowland, St. Thomas's; K. J. Rustome, Liverpool; J. F. Ryan, St. Thomas's; S. Sacke, London; J. J. A. Scott, Birmingham; G. R. Sharp, London; S. C. Shaw, Middlesex; M. O. Simon and K. L. Singer, Middlesex; B. L. Skoggs, St. Bartholomew's; E. H. B. Sparrow, Birmingham; H. J. R. Surrage, Cambridge and King's College; R. Thorne, London; A. R. Tohill, Charing Cross; R. E. S. Webb, Middlesex; A. G. B. Wilcock, Cambridge and St. George's; W. G. Woolrich, Cambridge and St. Thomas's; A. F. Wyatt, London; G. Zachariah, dasras; and I. H. Zierman, London.

**Surgery.**—P. A. Ashcroft, Manchester; D. C. Beaumont, Cambridge and London; W. T. Bewick, Cambridge and St. Thomas's; A. H. Binn, Northwestern University, Chicago; E. D. Bouter, Cambridge and University College; C. C. Caesterman, Bristol; G. F. Cobb, St. Bartholomew's; E. J. Coombes, St. George's; P. G. S. Davis, St. Thomas's; H. Gainsborough, Cambridge and St. George's; M. Gourevitch, Paris and London; Grace Mary Giulson, Griffith, Cardiff and Leeds; H. W. H. Holmes, Cambridge and St. Thomas's; C. Holt, Bombay and Middlesex; O. H. Hyman, St. Thomas's; Eleanor Joyce Partridge, Royal Free; R. E. Rampling, St. Thomas's; D. W. R. Richardson, Cambridge and London; and F. F. Tizard, Toronto.

**UNIVERSITY OF BRISTOL.**—At the Second Examination for the Degrees of M.B., Ch.B. (Part I.), held recently, the following candidates were successful:

Khai Way Chan, William Lorimer Cosham, Nan Susan Jolie Roberts, and Marjorie Wadsworth.

**ROYAL MEDICAL BENEVOLENT FUND.**—At the last meeting of the committee, held on Jan. 9th, 12 cases were considered, and £112 voted to 10 of the applicants. The following is a summary of the cases relieved:

Widow, aged 63, of M.R.C.S. Eng. who practised in Suffolk and Cambridgeshire, and died in 1914. Left quite unprovided for, and until recently earned a bare income by acting as nurse-midwife. About four months ago became ill, and is now suffering from paralysis, and the small amount of money saved is almost exhausted. Voted £12 in 12 instalments.—Widow, aged 75, of L.S.A. Lond., who practised in Bermonsey, and died in 1897. Applicant managed up to the commencement of the war by keeping a boarding-house on the south-east coast, but has had to close it down, and is still responsible for various charges against the house. Two children, who help all they can. Relieved once, £15. Voted £12 in 12 instalments.—L.R.C.P. & S. Edin., age 59, a widow, who practised in Dumbartonshire and is now suffering from spasmodic paralysis. Only income a pension from the National Hospital of £20. Has one son, who is training for a dentist, and whose fees have been provided by the Fund and Guild. Received 12 times, £144. Voted £12 in 12 instalments.—Widow, aged 63, of L.R.C.P. Irel., who practised at Buckley and died in 1905. Applicant was totally unprovided for, and had been an invalid for many years and unable to work. One daughter married and unable to help. Only income a pension from the society of £25. Relieved nine times, £108. Voted £12 in 12 instalments.—Widow, aged 77, of M.R.C.S. Eng. who practised at Runcorn and Swanson and died in 1914. Applicant was left unprovided for, and is suffering from mitral stenosis and unable to help herself. One daughter, now eight years old. Applicant lives with her mother, whose means are very limited. Relieved twice, £24. Voted £12 in 12 instalments.—Widow, aged 54, of M.R.C.S. Eng. who practised in Devonshire, and died in 1914, and was an annuitant of the Fund. Applicant was left without means, and finds it very difficult to obtain suitable work on account of ill-health and age. One daughter, aged 22, who is in domestic service. Relieved four times, £28. Voted £12 in 12 instalments.—Daughter, aged 50, of M.R.C.P. Lond., who practised in London and died in 1910. Applicant lost practically all her income through a defaulting trustee, and has now only £16 per year. Her health is very precarious. Her mother, who was helped by the Fund, has recently died. Relieved three times, £40. Voted £18 in 12 instalments.—Widow, aged 63, of L.R.C.S. Edin., who practised on the West Coast of Africa and died in 1917. Was left unprovided for, and has recently had an operation for gall-stones and gastric ulcer. Has three children, all absent and unable to help. Relieved five times, £60. Voted £12 in 12 instalments.—Daughter, aged 64, of M.R.C.S. Eng. who practised in London and Watford and died in 1879. Applicant was left unprovided for, and owing to ill-health unable to do much work. Only income a pension from another charity. Relieved 10 times, £117. Voted £9 in 12 instalments.

Subscriptions may be sent to Dr. Samuel West, honorary treasurer, at 11, Chandos-street, Cavendish-square, London, W.

**THE ASSOCIATION OF INFANT WELFARE: A DEPUTATION TO LORD RHONDDA.**—A deputation from the Association of Infant Welfare and Maternity Centres has approached the President of the Local Government Board in regard to State help for the adequate feeding of mothers and young children, urging the extension of the present Government grant of 50 per cent. of the approved expenditure of welfare centres to cover the cost of supplying milk to children under school age and nourishment for nursing and expectant mothers in necessitous cases. Dr. Eric Pritchard pointed out the difficulty

for mothers under present circumstances of providing the necessary 1½ pints of milk per day for artificially fed babies, and the still greater difficulty in affording as much milk as was really needed for children from 9 months to 3 years, if they were to grow up sound and strong. He stated that a small quantity of sugar, now difficult to obtain, was vitally necessary for children under 18 months of age. Dr. Flora Shepherd stated that, in her experience, the provision at welfare centres of suitable meals for mothers largely increased the proportion of breast-fed babies. Lord Rhondda, in a sympathetic reply, foreshadowed early legislation to increase the powers of local authorities in the direction indicated.

MANCHESTER and district have contributed £47,000 in aid of the fund for the relief of blinded sailors and soldiers.

DUBLIN UNIVERSITY PARLIAMENTARY ELECTION.—The polling in this election began on Jan. 30th and closed on the afternoon of Feb. 5th. The net number of votes polled was: For Mr. A. W. Samuels, 1487; and for Sir Robert Woods, 679. Sir Robert Woods's supporters are satisfied at the result of the contest, as their candidate had only been before the constituency a few weeks. Sir Robert Woods has declared his intention of presenting himself as a candidate at the first vacancy which may occur in the representation of the University in Parliament.

## Appointments.

*Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BRAMWELL, EDWIN, M.B. Edin., F.R.C.P. Lond. and Edin., has been appointed one of the Medical Referees under the Workmen's Compensation Act for the Sheriffdom of Fife.  
CUNNINGTON, C. WILLIETT, M.B., B.C. Camb., Acting Physician to Out-patients at Great Northern Central Hospital.  
GEORKE, R. J., M.D. Edin., Certifying Surgeon under the Factory and Workshop Acts for the Padstow District of the county of Devon.  
JACKSON, J. C., M.R.C.S., L.R.C.P. Lond., D.P.H., Deputy Medical Officer of Health for Hammersmith, *pro tem.*  
POOLER, H. W., M.B., B.Ch. Birm., Medical Officer to the Shirland District of the Chesterfield Union.  
VAN COLLIER, A. S., Senior Medical Student; Glasgow University, Assistant House Surgeon for General Infirmary, Greenock.  
WATSON, J. C., M.B. Edin., Certifying Surgeon under the Factory and Workshop Acts for the Lydbrook District of the county of Gloucester.  
WILSON, A. C., M.D. Glasg., Medical Officer to the Clay Cross District of Chesterfield Union.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.*

DERBYSHIRE ROYAL INFIRMARY, DERBY.—House Physician and Casualty Officer. Also Resident Anaesthetist. Salaries £200 per annum, with board, &c.  
DUMFRIES, CHICHTON ROYAL.—Temporary Pathologist and Clinical Pathologist, unmarried. Salary £300 per annum, with board, &c.  
EDINBURGH PARISH COUNCIL, CRAIGLOCKHART POORHOUSE AND HOSPITAL.—Assistant Medical Officer. Salary £250 per annum, with board, &c.  
GUILLIFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £200 per annum, with board, &c.  
KENT EDUCATION COMMITTEE.—Temporary School Medical Inspector and Medical Officer of School Clinic. Salary at rate of £350 per annum.  
MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Senior House Surgeon. Salary £250 to £300 per annum.  
MANCHESTER, BAGULEY SANATORIUM FOR TUBERCULOSIS.—First Assistant Medical Officer, unmarried. Salary £300 per annum, with board, &c.  
MANCHESTER COUNTY ASYLUM, Prestwich.—Locum Tenens. Salary £7 7s. per week, with board, &c.  
MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road.—Female House Surgeon. Salary £120 per annum, with board, &c.

MANCHESTER ROYAL INFIRMARY.—Resident Medical Officer. Salary £225 per annum, with board, &c.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—Junior House Physician. Salary £150 per annum, with board, &c. Also Female Co-examiner to School of Massage.

NEWPORT COUNTY BOROUGH.—Medical Officer for Maternity and Child Welfare Scheme. Salary £350 per annum.

NORTHERN HOSPITAL, Winchmore Hill, N.—Tuberculosis Wards: Resident Temporary Assistant Medical Officer. Salary 7 guineas per week.

NOTTINGHAM AND MIDLAND EYE INFIRMARY.—Female Resident House Surgeon. Salary £120 per annum.

PARISH OF ST. GILES' CAMBRKWELL, INFIRMARY, Brunswick-quare, Camberwell.—Two Locum Tenens Assistant Medical Officers. Salary £7 7s. weekly, each with board, &c.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green.—Temporary Assistant Physician to Out-patients.

ROTHERHAM HOSPITAL.—Junior House Surgeon. Salary £150 per annum, with board, &c.

ST. MARK'S HOSPITAL, City-road, E.C.—House Surgeon. Salary as arranged, with board, &c.

ST. PETER'S HOSPITAL FOR STONE, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £75 per annum, with board, &c.

SAFEGARD ROYAL HOSPITAL.—House Surgeon and Junior House Surgeon. Salaries at rate of £200 and £150 per annum respectively, with board, &c.

STAFFORDSHIRE EDUCATION COMMITTEE.—Female Assistant School Medical Inspectors. Salaries at rate of £400 per annum.

SUNDERLAND ROYAL INFIRMARY.—Female House Surgeon. Salary £150 per annum, with board, &c.

UNIVERSITY OF LONDON.—External Examiners.

## Births, Marriages, and Deaths.

### BIRTHS.

ARCHER.—On Jan. 23rd, to Ada Caroline, the wife of Charles W. Archer, F.R.C.S., Temp. Surgeon, R.N.—twin daughters.

FENN.—On Feb. 2nd, at Lancaster-place, Hampstead, N.W., the wife of Captain C. E. Fenn, R.A.M.C., of a daughter.

HUDSON.—On Jan. 29th, at the Flore de Nightingale Home, to Major and Mrs. Bernard Hudson, R.A.M.C., of Davos-Platz, Switzerland—twin sons.

JAMES.—On Jan. 29th, at Rose-lane, Llanon, Aberystwith, the wife of Captain Gwilym James, R.A.M.C., of a daughter.

LAMGRISHE.—On Feb. 3rd, at The Park, Beckenham, Kent, the wife of Captain (temporary Lieutenant-Colonel) J. du Plessis Lamgrishe, R.A.M.C., of a son.

MYER.—On Feb. 6th, at Cambridge-terrace, Hyde Park, the wife of Leonard Myer, F.R.C.S., of a daughter.

PINCHING.—On Feb. 4th, at Framp-on-on-Severn, Stonehouse, Glos., the wife of W. G. Pinching, M.R.C.S., L.R.C.P., of a son.

POOLEY.—On Feb. 3d, at Highfields, Chew Magna, Somerset, to K. Priscilla (née Bright), wife of Captain John Sandy Pooley, R.A.M.C., S.R.—a son.

Pritchard.—On Jan. 29th, at West Side, Wandsworth Common, the wife of Edward J. Pritchard, M.R.C.S., L.R.C.P. Lond.—a son.

SMITH.—On Jan. 27th, at M'ville-street, Edinburgh, the wife of Captain A. Nimmo Smith, R.A.M.C., of a son.

### MARRIAGES.

COURTENAY—ASHWORTH.—On Feb. 3d, at St. Paul's Church, Onslow-square, S.W., by the Rev. Peb Webb-Peploe, assisted by the Rev. A. C. Ashworth, brother of the bride. Ashley Reginald (Lieutenant, A.S.C.), elder son of the Rev. and Mrs. C. C. Courtney, Rome, Italy, and Edith Kennedy, younger daughter of J. Henry Ashworth, M.D. St. And., M.R.C.S. Edin., of Vigne House, Cliftonville, Kent.

ELTON—MAULE.—On Jan. 30th, at St. Mary's Church, Huntingdon, Henry B. Elton, M.B., to Mary Constance (Molly), younger daughter of Mr. and Mrs. J. Percy Maule, The Views, Huntingdon.

LEWERS—ASHWORTH.—On Feb. 3d, at St. Paul's Church, Onslow-square, S.W., by the Rev. Peb Webb-Peploe, assisted by the Rev. A. C. Ashworth, brother of the bride. William Hartley Nicholson, elder son of Arthur H. N. Lewers, M.D. Lond., F.R.C.P., of 15, Southwick-street, W., and Winifred Louise, elder daughter of J. Henry Ashworth, M.D. St. And., M.R.C.S. Edin., of Vigne House, Cliftonville, Kent.

MUIRHEAD—HALL.—By special licence, at St. Andrew's Church, Sharrow, Sheffield, by the Rev. C. Non Allen, on Jan. 20th, William Martin Muirhead, temporary Captain, R.A.M.C., son of Mr. and Mrs. Hugh Muirhead, Fulwood, Sheffield, to Gladys, young st daughter of the late William E. Hall and of Mrs. Hall, Sharrow, Sheffield.

RAWSON—FURNIVAL.—On Feb. 1st, at Metheringham, Captain P. H. Rawson, R.A.M.C., M.C., S. S. affe., to Mary Elizabeth, second daughter of Mr. R. B. Furnival, The Mead, Handforth, Cheshire.

### DEATHS.

BRUCE.—On Feb. 3rd, suddenly, in London, Robert Bruce, J.P., M.R.C.S., of Hillyfield, Millerton-Sea, Hants, aged 63 years.

HARDEY.—On Jan. 31st, at Spring-bank, Hull, Edward Pelroe Hardey, M.R.C.S., L.R.C.P., aged 70 years.

OLIVER.—On Feb. 1st, at his residence, Parkfield-road, Liverpool, John Brown Oliver, M.D., M.R.C.S., L.S.A., in his 82nd year.

PROWSE.—On Feb. 5th, at Saville-place, Clifton, Bristol, William Prowse, M.R.C.S., in his 92nd year.

ROCK.—Lost by the sinking of H.M.S. Laurentic, on Jan. 25th, Frank Ernest Rock, M.D. Lond., D.P.H., Surgeon, R.N.

SHILLINGFORD.—On Jan. 31st, Frank Norton Shillingford, M.R.C.S. Eng., Wisteria-road, Lee, S.E., aged 57 years.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

### THE CONSERVATIVE TREATMENT OF BURNS AND SCALDS.

To the Editor of THE LANCET.

SIR.—Dr. G. J. O'Reilly's communication in your issue of Jan. 27th gives food for reflection, especially in regard to aseptic scalds and burns. The torture endured by the victims, on which he lays emphasis, must undoubtedly add greatly to the shock of the injury and contribute to the delay or prevention of recovery. Perhaps I may be allowed to relate an experience of my own bearing on the subject.

Some years ago, as the result of an accident, about two gallons of boiling water fell on my bare right foot. The rapidly ensuing pain was in the highest degree unbearable, and I instinctively plunged the foot into a washing-basin half full of water in which a breakfast-cupful of bath salt had been dissolved overnight, to which I added a dessert-spoonful of bicarbonate of soda. I immediately felt relief, but I thought it right to send out as soon as possible for camomile oil and the usual dressings, including cotton-wool. In about a minute from their application the pain had returned in all intensity. I then had a foot-bath prepared containing common salt and bicarbonate of soda, in about the proportions indicated, at a temperature of 90° F. The effect was as if the foot had been immersed in liquid fire, but as soon as the temperature was reduced to 80° F. I was completely at ease. Meanwhile, unknown to me, the late Mr. John Langton had been summoned. I well remember the puzzled expression his face wore when, armed with morphia and syringe, he entered the room to find me heartily partaking of breakfast and reading the morning paper. He punctured a bulla extending over the dorsal aspect of the foot and toes and subsidiary ones about the ankles; and returned at 11 P.M. similarly provided to find me in bed in perfect comfort. Pressed to define the sensation in my foot, I explained that it had the character of a nettle-sting, but was much less severe. Indeed, it was scarcely noticeable. After an excellent night I resumed the foot-bath, maintaining a temperature of from 70° to 80° F. up to the afternoon of the third day, when I drove out, wearing a slipper, and for two hours visited patients, going up and down several flights of stairs. The result was rapid filling of the bullae, the appearance of a zone of redness at their margins, and a modern return of pain. I resumed the treatment until the morning of the fifth day, on which I returned to work and went about as usual with impunity. Desquamation went on for six weeks.

Since then I have both carried out and recommended the treatment described with uniform success. The most recent case was that of a scald of the hand from the wrist to the finger-tips. The patient was persuaded in the first instance to carry out the more orthodox treatment and passed the night in great pain. On the following morning the hand was bullous from wrist to finger-tips, of an angry red colour, and the fingers were in shape like large sausages and immovable. The saline bath at 80° F. or a little less was then adopted. The relief of pain was immediate, and by the afternoon the swelling had so far subsided that the fingers were freely movable. A rapid recovery ensued. Both the cases cited were scalds of the second degree.

It is within my memory that an Austrian archduchess set fire to her dress while holding a cigarette behind her. She was fearfully burned over the greater part of her body, and she was immersed in a bath to facilitate removal of portions of her clothing and the cleansing of her wounds. Every time that an attempt was made to remove her to a bed the pains became unbearable, and the unfortunate princess remained immersed until she succumbed to shock on the third day.

I am, Sir, yours faithfully,

W. BEZLY THORNE.

#### EDIBLE SEAWEED.

INTEREST seems to be reviving in many old-fashioned forms of food, promoted, no doubt, by the increased activity of the German submarines. Laver-bread has received popular attention lately. It is a sort of food made from green-laver (*Ulva latissima*), sometimes called "oyster-green" from being frequently attached to oysters. Other names for it are "sea-lettuce" or "marine sauce." It has a broad, flat membranaceous frond of a brilliant green, and throws itself into folds and puckers with the movement of the water. It has been used in Scotland, where it is called the "green sloke," not only for food but as a sort of water-dressing bound round the temples, and is considered efficacious as a remedy for headache, after the fashion of fresh cucumber-peel applied to the forehead.

There is another variety called the *Porphyra laciniata*, or the "purple laver," which is said to have a better flavour Hooker, writing in 1833, says:—

This, under the name of Laver, is much eaten in many places, especially the south of England, pickled with salt and preserved in jars, and when brought to table, served up with lemon juice. According to Lightfoot, the inhabitants of the Western Islands gather it in the month of March and after pounding and macerating it with a little water, eat it with pepper, vinegar and butter. Others stew it with leeks and onions.

Pavy, writing in 1875, said that—

Dr. Letheby urges the advisability of extending the use of so valuable and abundant a stock of food which already enters largely into the diet of some of the coast inhabitants of Great Britain, Ireland, and the Continent. Before being cooked they require to be soaked in water, to remove their saline matter. They are then stewed in water or milk until they become tender and mucilaginous. Sometimes they are pickled and eaten with pepper, vinegar and oil or with lemon juice. The consumption of laver is thought to be useful in scrofulous affections and glandular tumours.

Another edible seaweed which is well known is "Irish moss" or "Carragheen" (*Chondrus crispus*), used in chronic bronchial affections and in diarrhoea, dysentery, and renal disorders. It has also been used for making soup, a kind of blancmange, and size. Some other seaweeds are said to reduce corpulence. The Japanese and Chinese have used edible seaweed for a long time as food in the shape of sweetmeats, and even as biscuits or bread. Many years ago specimens of these were brought to London and put on exhibition. They certainly looked appetising enough. Another food obtained from the edges of the sea is samphire (a corruption of Saint Pierre), which is likewise pickled and eaten with vinegar. The green tubular stalks are sucked or drawn off a central, fibrous, thread-like stem.

#### HOW TO RATION THE HOUSEHOLD.

THE National Food Reform Association has issued three pamphlets in series, entitled "Facts for Patriots" (3d. each), from the office of the association, 178, St. Stephen's House, Westminster. These pamphlets have already helped many to revise and reduce their food expenditure, and it is believed that the changes have been effected with profit rather than prejudice to the health of the households. Dealing with the economical use of meat, fish, meat substitutes, the proper place in the dietary of bread and flour, sugar and sweets, milk, vegetables, fruit, and salads, they supply useful information for the moment. Copies, with recipes, may be obtained, post-free, by forwarding 1s. 3d. to the honorary secretary.

Supplementary and more scientific information will be found in Professor Bayliss's book on the "Physiology of Food and Economy in Diet," which Messrs. Longmans will shortly publish. It deals with such subjects as the uses of food, the quantity required, digestibility, vegetarianism, and other problems which are of importance not only in war-time but in times of peace. No previous knowledge of physiology is assumed. The same firm have in the press a new edition of "One Hundred and One Practical Non-Flesh Recipes," by Margaret Blatch, late principal of the Eustace Miles School of Cookery. It is hoped that the amateur cook will be able to work from these recipes as easily as the professional.

#### SWAZILAND.

THE Swaziland Protectorate (called by the natives Kwa-Ngwanne) lies between the Drakensberg and Lebombo Mountains in British South Africa. The Transvaal Province forms a boundary on the south, west, and north, the eastern boundary being Zululand and the Portuguese province of Mozambique (Delagoa Bay). The country was formerly under the administration of, but not incorporated with, the South African Republic; it is now controlled by the British Government. The total area is 6536 square miles, and the population, according to a census taken in 1911, amounts to 99,959, of whom 1083 are Europeans, the bulk of the remainder being natives—Ama-Swazi Bantus (or Swazis). According to the Blue Book for 1915 the general health of the community during the year was good. There has been no serious epidemic of any kind. As the result of a dry season there was less malaria than usual. There are sporadic cases of enteric each year, but as a rule this disease runs a mild course. There are a few cases of leprosy amongst the native population and these are isolated as far as possible. Births and deaths of natives are not registered. Amongst Europeans the births during the year numbered 42, or approximately 35 per 1,000, and the deaths 12, or approximately 10 per 1000. The only hospital is at Mbabane. To this 83 patients were admitted, of whom 6, including 2 Europeans died; there were 1920 out-patients. The uneducated native makes but little use of the services of the Government medical officers, which services are provided free in most cases; he prefers to be treated by his own medicine man. In the malarial districts, however, the beneficial effects of quinine, which is distributed free by the Government, are being appreciated by the natives.

## Medical Diary for the ensuing Week.

### SOCIETIES.

**ROYAL SOCIETY,** Burlington House, London, W.

**THURSDAY.**—Papers:—Dr. J. H. Mummery: On the Structure and Development of the Tubular Channel of the Sparids and Labridae (communicated by Prof. J. Symington).—Miss H. Chick and Miss E. M. M. Hume: The Distribution in Wheat, Rice, and Maize Grains of the Substance, the Deficiency of which in a Diet causes Polyneuritis in Birds and Beri-beri in Man (communicated by Dr. C. J. Martin).—Miss H. Chick and Miss E. M. Hume: The Effect of Exposure to Temperature at or above 100° C. upon the Substance (Vitamine) whose Deficiency in a Diet causes Polyneuritis in Birds and Beri-beri in Man (communicated by Dr. C. J. Martin).

**ROYAL SOCIETY OF MEDICINE,** 1, Wimpole-street, W.  
MEETINGS OF SECTIONS.

Tuesday, Feb. 13th.

**PATHOLOGY** (Hon. Secretaries—Gordon W. Goodhart, C. Price-Jones): at 5 P.M.

**Papers:**  
Major F. W. Mott, R.A.M.C., F.R.S.: (1) Changes in the Central Nervous System in Cases of Hypothyroidism; (2) Changes in the Central Nervous System in Cases of Shell Shock and Gas Poisoning.

Dr. Drinkwater: An Anatomical Abnormality inherited from the Fifteenth Century.

Thursday, Feb. 15th.

**DERMATOLOGY** (Hon. Secretaries—J. H. E. McDonagh, Henry MacCormac): at 5 P.M.

Dr. Graham Little: A Case of "Erythème Annulaire Centrifuge" (Darier).

Dr. J. M. H. MacLennan (for Dr. Allworthy): Photographs of a Form of Occupation Dermatitis occurring in the Flax-spinning Mills of Belfast and known as "Doffer's" Eruption.

Friday, Feb. 16th.

**OTOLOGY** (Hon. Secretaries—E. D. D. Davis, Somerville Hastings): at 8.15 P.M.

**Special Discussion:**

On "War Injuries and Neuroses of Otological Interest." To be opened by Mr. H. J. Marriage, F.R.C.S., President of the Section.

**NEUROLOGY.**—Members of the Section of Neurology are specially invited to attend the meeting of the above Section.

**ELECTRO-THERAPEUTICS** (Hon. Secretaries—E. P. Cumberbatch, Robert Knox): at 8.30 P.M.

**Paper:**

Dr. Martin Berry: Trauma in the Etiology of Arthritis.

**MEDICAL SOCIETY OF LONDON,** 11, Chandos-street, Cavendish-square, W.

**MONDAY.**—8.30 P.M., Paper:—Surg.-Gen. H. D. Rolleston, R.N., C.B.: Naval Medicine in the Great War.

**HUNTERIAN SOCIETY** at the Royal Society of Medicine, 1, Wimpole-street, W.

**WEDNESDAY.**—6.30 P.M., Council Meeting. 9 P.M., Hunterian Society Oration:—Dr. Langdon Brown: The Hunterian Tradition in Cardiac Research.

**ROYAL SOCIETY OF ARTS,** John-street, Adelphi, W.C.

**MONDAY.**—4.30 P.M., Cantor Lecture:—Prof. A. B. Pite: Town Planning and Civic Architecture. (Lecture III.)

**WEDNESDAY.**—4.30 P.M., Mr. L. Chubb: Highways and Footpaths.

**MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND,** 11, Chandos street, Cavendish-square, W.

**THURSDAY.**—3 P.M., General Meeting. Paper:—Dr. R. Armstrong Jones: Dreams and their Interpretation, with Reference to Freudism.

**SOCIETY OF TROPICAL MEDICINE AND HYGIENE,** 11, Chandos-street, Cavendish-square, W.

**FRIDAY.**—5.30 P.M., Paper:—Miss H. Chick and Miss E. M. M. Hume: The Distribution among Foodstuffs (especially those suitable for the rationing of Armies) of the Substances required for the Prevention of (a) Beri-beri and (b) Scurvy.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND,** Lincoln's Inn Fields, W.C.

**MONDAY.**—5 P.M., Hunterian Lecture:—Prof. J. Hutchinson: On Dupuytren's Contracture. Dupuytren's Life and Surgical Works.

**WEDNESDAY.**—5 P.M., Hunterian Oration:—Sir George H. Makins, K.C.M.G., C.B.: Hunter's Influence on Military Surgery.

**POST-GRADUATE COLLEGE,** West London Hospital, Hammerton-street, W.

**MONDAY.**—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

**TUESDAY.**—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

**WEDNESDAY.**—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pernet: Operations.

**THURSDAY.**—2 P.M., Medical and surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

**FRIDAY.**—10 A.M., Dr. Simson: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

**SATURDAY.**—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pernet: Operations.

**ROYAL INSTITUTE OF PUBLIC HEALTH,** Lecture Hall of the Institute, 37, Russell-sq., W.C.

Courses of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

**WEDNESDAY.**—4 P.M., Lecture V.:—Lieut.-Col. S. A. M. Copeman, M.D.: The Prevention and Arrest of Infectious Disease in War Time. Lieut.-Col. D. Harvey, R.A.M.C., has promised to take part in the discussion.

**ROYAL INSTITUTION OF GREAT BRITAIN,** Albemarle-street, Piccadilly, W.

**TUESDAY.**—3 P.M., Prof. C. S. Sherrington: Pain and its Nervous Basis. (Lecture V.)

### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To the EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C.

### MANAGER'S NOTICES.

#### VOLUMES AND CASES.

VOLUMES for the second half of the year 1916 will be ready shortly. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half-year's numbers (inland edition) are now ready. Cloth, gilt lettered, price 2s., by post 2s. 4d.

To be obtained on application to the Manager, accompanied by remittance.

#### ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8d. The rates of subscription remain as revised in October.

#### TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 4.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

#### METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Feb. 7th, 1917.

## The Hunterian Oration

ON THE

### INFLUENCE EXERTED BY THE MILITARY EXPERIENCE OF JOHN HUNTER ON HIMSELF AND THE MILITARY SURGEON OF TO-DAY.

*Delivered before the Royal College of Surgeons of England on Feb. 14th, 1917,*

BY SIR G. H. MAKINS, F.R.C.S. ENG.,  
K.C.M.G., C.B.,  
SURGEON-GENERAL, A.M.S.

**MR. PRESIDENT AND GENTLEMEN.**—This day 189 years ago witnessed the birth of John Hunter. Since the year 1814 it has been customary for a member of the Council of this College to deliver at stated intervals an address recalling the memory of that illustrious man. The speakers on these occasions have in turns devoted the short space of time at their disposal to either a philosophical disquisition, an attempt to form an estimate of the influence exerted by Hunter on the surgical thought of his time, or to dwell upon some portion of the writings he has left us. My own powers are unequal to the first task, while my knowledge of the state of surgery as Hunter found it is too limited to allow me to essay the second. I therefore propose to deal briefly with his work as a military surgeon, and to try to show what influence this may have had on his successors and upon himself, and how far the views which he held and taught deviate from those which guide the military surgeon of to-day.

I think the divergence is not a very wide one, for although some of the most modern surgical practice has been spoken of as a *revolution*, yet the general tendency has rather been in the direction of a *reaction*. I believe that this reactionary character has been as striking in the surgery practised during the present war as it has been in the military methods employed. I may instance the return to the direct transfusion of blood, the performance of excision of joints in the early stage of acute arthritis, the extensive operations for head injuries, and the character of the methods of wound treatment advocated by some; even in the case of the chief triumph of recent military surgery, operations for injury of the hollow abdominal viscera, the advance has depended rather on the favourable conditions furnished by the nature of the warfare than on any change in surgical principles.

#### HUNTER AS MILITARY SURGEON.

Of John Hunter's actual life and doings in the field we know little. In the year 1760 he went as surgeon on the staff to Belleisle and Portugal, his term of active service amounting to two years, while in 1790 he was appointed Inspector-General of Hospitals and Surgeon-General of the Army. It is, perhaps, not astonishing to find that not a small share of the meagre correspondence at our disposal is devoted to matters regarding promotion, pay, the character of his seniors, and the social qualities of his colleagues. The world and military life have, no doubt, altered but little in these respects.

With the exception of his own writings, nothing remains of the surgical history of the wars in which he took part. This is to be explained by the fact that the wounded men were transferred on board ship as quickly as possible and sent to England. Hence Hunter, as is the case with his successors of to-day, was afforded but small opportunity of following out the complete history of the majority of the patients who may have come under his care. His own brief mention of his work is characteristic enough; he says in one of his letters<sup>1</sup>:—

"Thank God I have succeeded in everything I have attempted, but my practice in gunshot wounds has been in a great measure different from all other, so that I have had the eyes of all the surgeons upon me, both on account of my supposed knowledge and method of treatment."

How far Hunter's immediate colleagues agreed with his opinions and practice it is impossible to tell, but that his influence at a later date was great is evident from the comments of the next great military authority belonging to our own College. Mr. Guthrie says<sup>2</sup>:

"Hunter served for a few weeks in 1761 at the siege of Belleisle, and it is much to be regretted that his opportunities were not sufficiently numerous to enable him to draw such inferences from them as would have left but little to desire. The greater part of what he did leave was from this cause found not to accord with the observations made by his successors, while the prestige attached to his name was so great, as much to impede their progress on many essential points."

An examination of Guthrie's writings does not, however, appear to afford much support to this statement, except in so far as Hunter's disinclination to perform either primary or intermediate amputations is concerned. We shall perhaps do better therefore to examine shortly for ourselves the material which Hunter left behind him, and judge how far his opinion and teaching differ from those of to-day. While, however, confining ourselves for the most part to the two lectures especially devoted to "The Treatment of Gunshot Wounds," we must bear in mind that Hunter states that his "extensive opportunities of attending to gunshot wounds" drew his attention to the subject of "inflammation in general" and enabled him to make observations which formed the basis for his "Treatise on the Blood and Inflammation."

#### HUNTER'S WRITINGS ON GUNSHOT WOUNDS.

The two lectures on "The Treatment of Gunshot Wounds" differ considerably in character from the series devoted to general surgery. They are more simple and direct, less overlaid by theory, and consist for the most part of clinical observations and practical instructions. Perusal of them furnishes some support to Guthrie's criticism, in that the illustration of some of the statements made is found in descriptions of cases met with at a later date in civil practice. An equally satisfactory explanation of this occurrence is, however, offered by the fact that for these lectures, as in all Hunter's writings, the material on which they are based was collected many years before the time at which it was utilised for publication.

In the second lecture devoted to gunshot injuries of the special regions of the body little is included which is not equally applicable to the subject to-day. In dealing with the subject of injuries to the head Hunter belonged to the active school—any injury appeared sufficient excuse for trepanning the skull. He dwells on the necessity of raising a sufficiently extensive flap to allow of proper exploration of injury to the skull, and speaks of the propriety of incising the dura mater in some instances. With regard to the latter procedure, however, he says: "Whenever I have seen the dura mater opened, the brain has worked through the opening, and the patients have died" (i., 495); hence he recommends caution.

The favourable prognosis attendant upon wounds of the chest is recognised, also the importance of collapse of the wounded lung in restraining primary haemorrhage and the tendency of the blood effused into the pleural cavity to clot (iii., 353). Hunter made a number of experiments on the production of pneumothorax, &c., on dogs, and recommends "the operation for the Empyæma" in cases of haemothorax. It does not appear, however, whether he ever performed this operation.

In the section on injuries to the abdomen the expectant method of treatment is imposed, and this perhaps especially because Hunter was familiar with the favourable course which followed the formation of a secondary faecal abscess and fistula when the colon has been injured. In the matter of diagnosis no great advance has been made since his time, except that dependent on the use of the X rays in localising the seat of foreign bodies. The value of localised pain and tenderness as a diagnostic aid is dwelt upon, also the various haemorrhages as signs indicative of injury to special viscera. Again, it is interesting to notice that he dwells upon the absence of any certain sign denoting injury to the spleen, also the fact that either the spleen or spleen and liver may be wounded without any obvious adverse result. The often re-discovered fact that there is little tendency for the contents to escape from a wound of

<sup>1</sup> S. Paget: Life of John Hunter, p. 75.  
NO. 4877.

<sup>2</sup> Guthrie: Commentaries on Surgery, p. 5.  
G

small intestine was also impressed by Hunter. In view of the modern treatment of septic peritonitis it is instructive to note that the suggestion is made of placing the patient in a tepid bath in order to supply fluid to the general constitution. Directions for treatment consist, however, mainly in instruction of how to deal with the secondary consequences of injuries to the abdominal viscera; as to primary lesions he says: "I should suppose the very best practice would be to be quiet and do nothing, except bleeding, which in cases of wounded intestine is seldom necessary."

Conservatism is impressed in the matter of primary removal of bone fragments in gunshot fractures and the too early interference with sequestra. Hunter, in fact, takes the same line in dealing with these, as he lays down in the case of retained missiles. "In general there can be no better way of coming to a part or extraneous body than by waiting for the formation of an abscess there."

The one point on which Hunter's immediate successors appear to differ most freely from him, is as to the line to be followed when an amputation has to be considered. He says, "I have already observed that few can support the consequences of the loss of a lower extremity when in full health and vigour"; hence he avoided primary amputation whenever possible, condemned operations of an intermediate nature, and preferred those of the secondary class.

We may now pass on to the question of the treatment of gunshot wounds in general, dealt with in the first lecture and throughout the whole "Treatise on the Blood and Inflammation."

#### WOUND TREATMENT.

Hunter's methods of treatment were guided by the views held by him on the pathology of the healing of wounds, and these methods were limited in consequence of his ignorance of the part played by infection as a cause of inflammation. Hence he is not concerned to differentiate between the process of repair and that of inflammation. He says:—

"The injury done has in all cases a tendency to produce both the disposition and the means of cure. The stimulus of imperfection taking place immediately calls forth the action of restoration" (iii., 239), yet "injuries often excite more action than is required" (iii., 260). Then inflammation is excessive, and this "may arise from a vast variety of causes with which we are at present unacquainted; may, which we do not perhaps even suspect" (iii., 407).

While he regarded suppuration as an unavoidable consequence of many wounds, yet he says "suppuration may be considered a resolution, but it is the mode of resolution we commonly wish to avoid" (iii., 369). Hence his attempts to diminish the degree of general reaction by blood-letting, and locally to effect an immediate closure of the wound. "In parts which have been divided and exposed the inflammation is in great measure prevented by bringing them together" (iii., 369), and when this cannot be done, "Nature attempts to prevent inflammation by covering the wound with blood and forming an eschar." Thus a power of resolution is shown "even in cases where the parts have been exposed."

It is of interest in this relation to recall that he combats the opinion promulgated by A. Paré and held long after that exposure to the air was in itself a cause of suppuration. "Exposure to air certainly has not the least effect on parts exposed, for a stimulus would arise from a wound even were the part contained in a vacuum." Air takes no part in the formation of an abscess, cellular emphysema is not attended by suppuration, the air itself in a pneumothorax is not a source of danger, nor is air necessary for the development of a gonorrhoea.

In describing the special characteristics of gunshot wounds, contusion is the feature upon which he lays most stress (iii., 545). He observes that the degree and extent of the contusion vary inversely with the velocity retained by the missile. Thus, the greater the velocity retained by the ball, the cleaner it wounds the parts, yet they slough; if the velocity is low the mischief is less and the ball more easily deflected. If the velocity be high, blood-vessels are divided instead of being contused; if it be very low they are torn.

The contusion of the tissues and the resulting slough prevent healing by the "first intention," "from which circumstance most of them must be allowed to suppurate" (iii., 543). Hunter observed that the tissue devitalised by contusion temporarily protected that lying beneath, and hence the advent of inflammation (infection) was retarded, an observation which still retains its force in the case of more modern projectiles. Hunter deprecates the practice handed

down from A. Paré and Wiseman of routine enlargement of gunshot wounds, and ascribes its origin to anxiety on the part of the surgeon to remove a foreign body. He then points out the difficulty often accompanying the attempt to extract foreign bodies, the fact that experience had shown that these might be left without evil consequences, and concludes that the custom of opening up wounds had been continued in ignorance of its primary object. He does not appear to have realised that the practice afforded an advantage not properly appreciated of affording drainage to an infected area.

Still, the rule "that it should not be opened up because it is a gunshot wound, but because there is something necessary to be done which cannot be executed unless the wound is enlarged" (iii., 549) is sound enough, as also the statement "this is common surgery and should be military surgery respecting gunshot wounds" (iii., 550), and is certainly to be preferred to that of Baron Percy enunciated so late as 1792, "the first indication is to change the nature of the wound as nearly as possible into an incised one."

Hunter, however, improperly undervalues the argument that enlargement of the wound takes off the tension arising from the inflammation because he considered inflammation a necessary consequence of gunshot wounds, and "any increase in the size of the wound was to be considered as an extension of the first mischief, and must be supposed to produce an increase of the effects arising from that mischief" (iii., 552).

He then proceeds to enumerate a number of conditions which call for enlargement of the wound which obviously hold good to-day; but "if none of these circumstances has happened I think we should be very quiet." Nevertheless, he recognised the danger of a contour wound and recommended an incision over the centre, or the laying open of the entire track, to avoid the danger of abscess formation and the occurrence of extensive suppuration—a danger not always appreciated as it should be in dealing with contour wounds of the head, chest, and abdomen even to-day.

#### LOCAL TREATMENT OF THE WOUND.

"The injury done has in all cases a tendency to produce both the disposition and the means of cure. The stimulus of imperfection taking place immediately calls forth the action of restoration" (iii., 239).

"The first and great requisite for the restoration of wounded parts is rest, as it allows that action which is necessary for repair to go on without interruption" (iii., 260).

In these two axioms we find the theory upon which Hunter's treatment of wounds was based. The dominating factor in the healing of the wound he held to be the vital process or action of the body, a principle dwelt upon in equal measure by his great successor Lister, and one to which, perhaps, too little attention is given even to-day by the originators and advocates of various local methods of wound treatment.

He drew little distinction between the process of repair and that of inflammation, regarding both as the consequences of an "operation" in which the blood-vessels took the major share, since in the state of knowledge then existing he was ignorant of the important part taken by increased activity of the fixed tissue element in addition. Again, his ignorance of the common dependence of inflammation on infection hampered him in devising any local form of application to the wound. Hence we find him mainly occupied with discussing the relative merits of a cold- or hot-water dressing and the advantages to be obtained by the use of the poultice which required to be less frequently reapplied, and could be removed more easily and with less pain to the patient.

Regarding the healing of a wound as a natural "vital operation" Hunter saw no greater mystery in this process than in the growth and development of the infant to the man. So to-day, in apportioning its relative value to any special form of wound treatment, we must bear in mind that it is difficult, aye, impossible, to prevent the healing of a wound, much as the process may be interrupted or distorted by extraneous causes.

#### WOUND TREATMENT IN THE PRESENT WAR.

During the past two years the local treatment of gunshot wounds has given rise to as lively and ardent discussion as that accompanying the introduction of the antiseptic principle by Lister during the earlier part of the last half-century. It appears as if the steady development of the "aseptic

principle" and its obvious success in civil practice had lulled the modern surgeon into a happy dream, from which he was suddenly awakened to the terrible spectacle of wounds infected in a proportion and to a degree to him almost incredible.

"As a ship which passeth over the waves of the water, which when it is gone, the trace thereof cannot be found, neither the pathway of the keel in the waves."

So, indeed, the experience of the pre-antiseptic surgeon seemed to have vanished and left no trace in the minds of men. This is perhaps the less remarkable in that the simple wounds inflicted by the bullet of small calibre in recent wars had proved themselves of little consequence in affording either a ready pathway for the entrance of infection or a fertile ground for its extension.

The antiseptic measures suited to meet the limited demands attendant on the practice of aseptic surgery, and in which trust was at first reposed, proved impotent when applied to the treatment of the severe and grossly infected wounds produced by the altered forms of missile employed in the present warfare. This disappointing experience was followed by a brief acute reaction in the direction of attempting an immediate and complete primary sterilisation of the wound by the application of powerful antiseptic media such as liquefied carbolic acid and strong solutions of mercurial salts.

It appears strange that attempts at complete primary sterilisation of the wounds should have found so much advocacy. No surgeon has ever succeeded in procuring immediate sterilisation of extensive infected areas of tissue by chemical media, and the striking statement made by Lister on this subject seemed to have been completely forgotten.

"If, for example, a pair of forceps is handed to the operator with the intervals between the teeth occupied by dry septic pus, and a portion of this dirt becomes detached and left in the wound, the evil cannot be corrected by any antiseptic wash that is now at our disposal or that the world is ever likely to see."<sup>3</sup>

This being Lister's view regarding the ill-effects liable to follow the detachment of a few particles of infective matter from the teeth of a forceps, we may readily assume what his opinion would have been as to the feasibility of complete primary sterilisation of gross infection dependent on the passage or impaction of fragments of shell and dirty clothing.

The complete failure of attempts at effective primary chemical sterilisation led to increased resort to mechanical cleaning of the wound by removal of devitalised and infected tissue by the knife and scissors, and to the employment of counter incisions for drainage, both to prevent extension of the infection and to effect a cure. These procedures have remained measures of primary importance whatever subsequent method of treatment may be adopted.

Bacteriological investigation of gunshot wounds during the process of healing has shown that whatever method of treatment may be adopted, a certain primary sequence of bacterial growth and development is maintained.

Examination of "smear" preparations taken during the first 12 hours reveals the presence of no organisms although cultures prove positive. This incubation stage is followed by the appearance first of micrococci and a highly varied flora of other organisms. These latter in a properly drained wound tend to die out rapidly, and in the course of five or six days micrococci alone may persist. This is the crucial period for the completion of sterilisation, and success depends on two factors: (a) the vitality of the natural process and (b) the efficiency of the method of treatment adopted.

As to the first factor, in a certain proportion of instances the vital powers will suffice, but in a considerable number either the primary reaction is deficient, the infection too gross to be efficiently dealt with, or the infection regains ascendancy when the initial reaction commences to fail in power.

Determination of the degree of activity and efficiency of the vital powers in any given case is impracticable, hence some general plan of treatment must be adopted for all. Opinion has been to some extent divided as to the most desirable method, and the chief differences have arisen in

connexion with the antiseptic system as laid down by Lister, and the physiological or phylacagogic system of Wright.

The question obviously resolves itself into that of the secondary sterilisation of wounds: in the one method an attempt is made to supplement the natural vital powers from without by the employment of chemical media to inhibit or destroy bacterial growth in the wound; in the second an attempt is made to modify and strengthen the vital powers by the local application of a simple physical process.

#### *Secondary Sterilisation of Wounds: Chemical Antiseptic Methods.*

In proceeding to a consideration of the comparative value of these two methods from the point of view of the surgeon it is well to first inquire what is to be hoped for by the use of chemical antiseptic media. Lister proved beyond any possibility of doubt the absolute efficiency of such media as prophylactic or preventive agents, yet both his teaching and writings indicate that he viewed the question of dealing with an established infection from an entirely different standpoint. Of this no better illustration can be found than in the sharp distinction which he drew between "bactericidal" and "inhibitory" media and the way in which he employed them respectively.

We may first ask is it possible by chemical means to effect the sterilisation of tissue lying beneath the surface of the wound? It has not been proven that any chemical antiseptic can penetrate the tissue in sufficient quantity or to a sufficient depth to exercise bactericidal powers, unless it is at the same time sufficiently powerful to damage or destroy the tissues themselves. As in other methods the deeper tissues must depend upon the vital process for sterilisation, or, as Lister terms it, the co-operation of the "natural antiseptic"—i.e., the constituent parts of the blood.

Before leaving this part of the question we may also ask whether a complete clearance of organisms from the tissues deep to the surface of the wound is a necessary preliminary to closure of the cavity. This question may be answered in the negative. Evidence is offered by the common observation that many wounds the surfaces of which are free of organisms may be safely and definitely closed if the surface be not disturbed or injured in the course of the operation, while others in which disturbance of the surface is necessary for the completion of the operation often flare up with a fresh infection. Moreover, the safety with which a serous cavity such as the peritoneal may be closed in the evident presence of a definite degree of infection supports this view; again, the less satisfactory experience of the long period during which the organisms which have given rise to an attack of osteomyelitis or enteric fever may remain latent, is familiar enough. A certain number of organisms may no doubt be safely left to their fate and for the tissues to deal with.

The virtues of chemical antiseptics are restricted to the power to render sterile the wound surfaces and the cavity included by them. If this sterilisation be effected the patient is protected from the dangers of a renewed direct extension of the infection and from the risk of absorption of toxins formed by the bacteria which may collect under pressure in the recesses of the wound cavity. Further, the dangers and ill-effects of prolonged suppuration may be avoided.

To effect this purpose Lister's essentials of a thoroughly trustworthy unirritating antiseptic, so stored up that it cannot be dissipated to a dangerous degree before the dressing is changed, must be fulfilled.<sup>4</sup> It is of interest to recall that Lister in 1870 made a suggestion for the primary treatment of gunshot wounds consisting in the provision of an abundant supply of external dressing soaked in an oily solution of carbolic acid,<sup>5</sup> and again during the Boer War suggested the use of a powder of the double cyanide of mercury and zinc as an antiseptic reservoir,<sup>6</sup> but neither of these methods was largely employed or successful in application.

#### *The Physiological Method.*

The phylacagogic or physiological method of Wright seeks to attain the same objects as the antiseptic method by the

<sup>4</sup> The Collected Papers of Joseph Lister, vol. II., p. 358, An Address on the Antiseptic Management of Wounds, 1893.

<sup>5</sup> Loc. cit., p. 161. A Method of Antiseptic Treatment Applicable to Wounded Soldiers in the Present War.

<sup>6</sup> Loc. cit., p. 331. Notes on the Double Cyanide of Mercury and Zinc as an Antiseptic Dressing.

<sup>3</sup> On the Principles of Antiseptic Surgery, Virchow's Festschrift, 1891, II., 344. The Collected Papers of Joseph Lister.

local application of a physical process to regulate, modify, and alternately augment the strength of the various factors involved in the normal vital reaction.

It seeks : 1. To maintain the patency of the opened-up lymphatic vessels and spaces which normally undergo closure in the same manner as the wounded blood-vessels, and to encourage an increased flow of lymph from the wound surface with the following objects. (a) To effect a natural lavage of the tissues. (b) To maintain an outward current in the flow and thus oppose the entrance of microbes into the tissues. (c) To utilise the bactericidal properties of the fluid. (d) To remove exhausted lymph from the tissues in place of leaving it to return by the normal route of the lymphatic circulation. (e) To maintain a moist surface to the wound, and wash away débris of devitalised tissue and bacteria. In this last particular simple irrigation on the part of the hypertonic or isotonic solutions plays an important part.

2. At a latter date to encourage and increase the number of migrating leucocytes, both with the view of increasing phagocytosis and providing a sufficient supply of active trypsin to aid the separation of sloughs.

The normal outflow of lymph is increased by the physical ("drawing") process induced by continuous irrigation of the wound with a hypertonic solution of sodium chloride, and the augmented migration of leucocytes by similar alternate irrigation with "isotonic" solution (normal saline).

Before attempting to gauge the relative value to be assigned to the antiseptic or to the phylacagogic methods respectively it may be at once allowed that in some instances the unaided normal vital reaction may attain parallel results when treatment with simple dressings or mere exposure to air and sunlight is adopted, but unfortunately such results form rather the exception than the rule. Hunter in referring to the good results which may follow primary closure of the wound, or closure by scab formation, deals with them as an exception, and tells us "thus a power of resolution is shown, even in cases where the parts have been exposed."

It may be proper here to offer some preliminary criticism as to the validity of the theory upon which the phylacagogic method is based. Hunter says : " Yet injuries often excite more action than is required " (iii., 260). It is, indeed, indubitable that in a large proportion of all wounds the activity of the reaction exceeds that necessary for the process of repair, or for sterilisation of the tissues, proceeding in some even to the undesirable degree of acute inflammation and tissue destruction. In fact, in the process of repair, as in the normal physiological processes of the body generally, a large margin of excess is allowed to meet possible accidents in the course of the closure of the wound.

I think we may therefore assume that the normal vital reaction is not, as a rule, deficient in activity, and that even in a wound that heals normally by granulation, both the outflow of lymph and the migration of leucocytes tend to be wasteful of the vital powers of the patient. Again, it must not be forgotten that an excessive lymph flow in itself is a serious drain upon the powers of the patient, a fact illustrated in a remarkable degree by the rapid emaciation seen to occur in the subjects of the multiple superficial wounds which have formed so strong a feature of the surgery of the present campaign. Lastly, any interference with the coagulation which limits the primary flow of lymph following the wound, tends to remove one of the most important barriers afforded by nature for the protection of the system from the dangers of absorption of organisms and their toxins from the infected area.

#### *Relative Value of Antiseptic and Physiological Methods.*

The most useful practical test of the efficiency of any method of wound treatment is furnished by observation of the date at which micro-organisms disappear from the surface of the exposed tissues and at which the wound may be safely and permanently closed by suture or other means. When subjected to this test the antiseptic method has proved itself more rapid and more trustworthy than the phylacagogic.

As an example of the antiseptic method, that known as the Carrel-Dakin is chosen, because it appears to fulfil the conditions already laid down, and because in the hands of its originator it has afforded admirable results which have moreover been repeated by other surgeons and in our camps. It may be at once allowed that the method demands special

care and exactitude in application, but such objections as may be raised as to its suitability for military surgery are of a practical and not of a theoretical nature. Such are the necessity of strict supervision of the standard composition of the solution of the hypochlorites employed, the need for care and judgment in locating the instillation tubes, the necessity of regularity in the instillations of the fluid, and the difficulty in some cases of ensuring that the patient's clothing and bedding do not get soaked. All these problems are more difficult of solution in military than in civil practice, but they are not insuperable, while the last trouble attends equally the irrigation forming a part of the phylacagogic method.

Allowing these practical difficulties, we find in compensation that the wound cleans more rapidly, firmer and healthier granulations form, the organisms die out more promptly, the occurrence of suppuration is reduced to a minimum, or actually avoided, secondary wound complications are rarer, and the wounds are fit for closure at a much earlier period. The treatment, moreover, attains success even when applied to suppurating wounds of some standing.

The special success which has attended the use of this method depends mainly on the highly ingenious plan of maintaining the constant supply of the antiseptic medium by specially devised tubes and on the character of the antiseptic employed. Other antiseptic methods, however, have attained results which, while less striking, yet are superior to those observed with the phylacagogic. Of these latter the most satisfactory have been the dressing with solution of hypochlorous acid (eusol) and the iodoform-bismuth method of Rutherford Morison.<sup>7</sup> The latter, which combines a maximum amount of rest to the wound, a "persistent storage" of an efficient inhibitory antiseptic, and a minimum of attention on the part of the surgeon, has much to recommend its employment in military surgery, where economy of time and labour is so important. Its employment as a primary method of treatment of gunshot wounds is, however, not free from serious risks, and therefore in the absence of further experience not advisable.

In application the phylacagogic method fails to realise the merits which have been claimed for it. The increased flow of serum from the tissues has proved of small value from the bactericidal aspect; the "fluid" "drawn" has been shown by other observers (Parry Morgan<sup>8</sup> and others) to be deficient in organic constituents, and hence incomparable to the normal lymph furnished in response to the stimulus of the original injury and resulting infection, and either in the "fluid" itself or admixtures of it with hypertonic salt solution organisms, such as the streptococci, grow freely. This deficiency in the quality of the "fluid" drawn is intelligible if it be regarded as the product of a local physical process exerted on the wound itself. Such a process can hardly be relied upon to induce great additional activity either in the fluid or cellular elements which are normally provided as a response to the combined stimulus of injury and subsequent infection on the organism as a whole, in which case we have to deal with a general vital reaction on the part of the entire system the whole intensity of which is directed upon the infected region. The phylacagogic method indeed, while attempting to increase the normal vital reaction within the tissues, an object not always to be desired, deals inefficiently with the extraneous elements in the wound cavity which form the main obstacle to normal healing.

In practice it is found with the phylacagogic method that the initial changes in the wound are slow, the tissues tend to become sodden, the separation of sloughs is delayed, and a longer period is required before the wound surface can be regarded as having reached the stage at which secondary closure can be effected. Hence the period in which secondary wound complications may arise is prolonged. Moreover, in cases treated by the hypertonic method which fail to reach the "closure" standard, a few days' treatment with an antiseptic often suffices to attain the result desired.

In passing from the subject of the local treatment of the wound we may conclude with Hunter that "the stimulus of imperfection taking place immediately calls forth the action of restoration"; further, that this vital operation may be most effectively aided not by striving to regulate and modify the process, but by attempting to nullify the influence of the factors which tend to distort and interrupt it.

<sup>7</sup> THE LANCET, 1916, II., 268.

<sup>8</sup> Brit. Med. Jour., 1916, I., 685.

*Gas Gangrene.*

I can scarcely leave the subject of wound treatment in the present war without a word of mention of the most serious wound complication that has had to be dealt with, gaseous cellulitis or gas gangrene.

I can find no evidence that Hunter was familiar with this scourge. In the lectures on gunshot wounds a case is quoted in which "air came out of the wound" during the process of removal of a ball from the abdominal wall, but no mention is made of any special condition of the tissues, and it may well have been a *Bacterium coli* infection secondary to a minor injury of the colon. Hunter was certainly conversant with the rapid decomposition, with development of cellular emphysema, which sometimes follows death as a result of a general anaerobic infection of the body; hence we must conclude that he would have been quick to detect a similar form of cellulitis during life.

It seems more than doubtful whether gas gangrene has ever before assumed such a serious aspect during war. The writings of Ambroise Paré make no mention of emphysema as a sign in the gangrenous wounds observed by him, neither do the more modern writings of Guthrie suggest that the hospital gangrene seen in the wars of the early part of the last century in any way resembled the "gas gangrene" of to-day. It is clear that Lister, when speaking of hospital gangrene, referred to a process similar to that described by Guthrie, and surgical text-books generally have based their descriptions of hospital gangrene on a complex of identical signs. On the other hand, anaerobic gangrene, under the title of "acute traumatic gangrene," has been individualised as a definite disease and its pathology to some extent elucidated.

It is clear that the form of hospital gangrene observed during the American War of the Rebellion coincided in character with that described by Guthrie, and it is specially mentioned that the process did not involve the muscles; lastly, no mention of "gas gangrene" has been made in any of the more recent campaigns.

Hence I think it must be allowed that the frequency of gas gangrene is to be regarded as a peculiarity of this war, referable, perhaps, to the nature of the soil, and perhaps to the abundant diet of the men and irregularity in defaecation. In the latter relation it is a striking fact that of a small series of patients who died as a result of wounds of the colon in every case a general post-mortem anaerobic infection of the blood rapidly took place.

On the other hand, hospital gangrene of the classical types has been conspicuous only by its absence; during a period of two and a half years I have only seen one or two cases which seemed to resemble the spongy form, although the membranous type has been occasionally seen.

**HUNTERIAN LIGATION.**

No individual procedure originated by John Hunter has preserved the freshness of his name to a greater degree than the operation for the cure of popliteal aneurysm. Every student of medicine at an early date of his career makes acquaintance with Hunter's canal, and later with the principle of proximal ligation.

In one respect the influence exerted on military surgery by the knowledge of the ease and safety with which proximal ligation can be performed has not been for the good. It has encouraged the employment of proximal ligation at the seat of election for secondary haemorrhage and even for primary bleeding from a wounded artery. Both these practices are to be condemned except in rare instances of absolute necessity.

It is to be regretted that Hunter himself did not write the paper describing his operation and the grounds upon which he was led to undertake it, but the paper by Sir Everard Home included among Hunter's writings opens up one question of considerable interest to-day. In at least one of the cases there described (iii., 604, Case 3), possibly in the first three both the femoral artery and vein were included in the ligation, in the fourth we are definitely told that the artery only was included. From that period onwards surgical opinion has been definitely to the effect that the greatest care should be taken when occluding a main artery to avoid all injury to the vein. In fact, every operation for the ligation of an artery has been so devised that the aneurysm needle is passed in a direction away from the vein in order to minimise the risk of injury to that vessel. This not alone to avoid the technical inconvenience of immediate haemorrhage, but also with the definite object of preserving the venous circulation intact.

*Effect of Simultaneous Ligature of Artery and Vein.*

Observation of a large number of coincident wounds of large arteries and veins has in no way endorsed the view that simultaneous occlusion of both artery and vein exercises any deleterious influence on the subsequent collateral arterial circulation and the vitality of the limb. In support of this statement a few examples illustrating the innocuous nature of operations for the occlusion of veins in general may be first given. Operations for the cure of varicose veins have demonstrated the ease with which a compensatory balance is attained when the blood is diverted from the larger channels. Occlusion of the internal jugular and other large venous trunks effected in order to prevent the diffusion of septic emboli (the process of septic thrombosis was, I believe, first observed and described by John Hunter himself (iii., 581)) has not given rise to obvious permanent trouble.

In a very considerable proportion of gunshot injuries to large arterial trunks the neighbouring vein is contused and becomes thrombosed, and this has not been shown to give rise to increased risk of gangrene of the limbs. Ligature of the common carotid artery together with the internal jugular vein *en masse* has been performed in cases of emergency without increased risk of the development of the cerebral anaemia and softening so often a consequence of ligature of the artery alone. Further, where simultaneous ligature of both artery and vein in other parts of the body has been obligatory on account of wounds of both vessels untoward events have not been observed.

Evidence, moreover, exists that under certain conditions simultaneous occlusion of both artery and vein is a preferable procedure. The first example, not an unmixed or simple one, may be sought in the results observed to follow the application of a single proximal ligature to the artery in cases of arterio-venous aneurysm or aneurysmal varices of the femoral vessels. In patients so treated during the South African campaign,<sup>9</sup> gangrene of the limb followed in more than 50 per cent. of the cases. The frequency of this accident finds a simple explanation if we consider what actually results from the operation. The main vessel being occluded and the direct arterial pressure from behind being abolished, blood which has been carried by the arterial collaterals to the distal portion of the injured trunk, instead of passing to the peripheral circulation, takes the course of least resistance backwards into the vein through the arterio-venous communication, and thus the limb practically bleeds to death much in the same way as if the distal end of the wounded artery opened on to the surface of the limb. Hence, the comparative safety of removal of the communication *en masse* and occlusion of all four openings by ligature.<sup>10 11</sup>

A more striking example is offered by the result of ligaturing the popliteal vein alone for the treatment of senile gangrene of the foot. W. A. Oppel,<sup>12</sup> ascribing the good results occasionally observed to follow arterio-venous anastomosis for the cure of this condition to control of the venous circulation and consequent rise in the blood pressure of the limb, was led to substitute simple occlusion of the popliteal vein to produce the same effects. In six cases thus treated the extremities were seen to recover not only their warmth and colour without the development of oedema, but also a certain degree of hyperaemia of the feet and toes.

On these and other grounds it must be admitted that the balance of the collateral circulation is likely to be more efficiently maintained if the vessels which carry it on more nearly correspond in size and consequent equality in the blood pressure and rate of flow. The elimination, in fact, of the capacious main vein is a real advantage, since this for the time affords a too ready channel of exit for the diminished arterial supply as well as an undesirable reservoir for stagnation.

These considerations lead me not only to regard obligatory simultaneous occlusion of a main artery and vein as a negligible factor in the risk of gangrene of a limb, but to hold, further, that the procedure is preferable whether the vein be wounded or not; the result of the combined procedure being to maintain within the limb for a longer period

the smaller amount of blood supplied by the collateral arterial circulation, and hence to improve the conditions necessary for the preservation of the vitality of the limb.

#### INFLUENCE OF HUNTER'S EXPERIENCE IN THE FIELD ON HIS LIFE WORK.

We may now turn from the question of how far the work of John Hunter has influenced that of the military surgeon of to-day to that of how his experience gained in the field may have influenced his own life's work.

Hunter was emphatically a student of nature; his early years were, as we know, spent mainly in the fields around his home, where he sought out such secrets as he could from his surroundings. This fallow period, while responsible for depriving him of a facile pen and literary style, yet no doubt opened his mind, developed habits of thought and observation, and affords some explanation of the superhuman task to which he set himself with such devotion in the later periods of his life.

The whole world was his book, and it is of some interest in passing to contrast the character of his upgrowth and surroundings with those of his greatest successor, Joseph Lister. Hunter gained his earliest inspiration from the limitless field of nature with naked eye and unbridled freedom. Lister, born into a home the cradle of the modern microscope, passed through a blameless career at school and college in a continuous atmosphere of scientific thought and investigation. Both great men devoted their whole energies to the cultivation of science throughout a busy and industrious life—Hunter throughout with a yearning for the pedestal, Lister concerned only with the success of his labours.

Hunter died in the midst of an incompletely and impossible task, while Lister had the incomparable satisfaction of witnessing the success of his own efforts, the goal reached, and the benefit to mankind immeasurable. Each illustrious man, however, perhaps found his proper field: Hunter in a life of continuous stress, immoderate labour, a struggle for his daily bread and the means to pursue his researches, and a tragic death not unsuited to the fiery nature of the man. Lister in a more equable existence, spent in steady and industrious pursuit of the one great object he had in view, and after attaining a success duly appreciated by the whole world passed quietly away in the zenith of his fame.

The abrupt change from a boyhood of untrammeled freedom to the life of a hard-worked demonstrator in a school of anatomy, than which no greater contrast can be conceived, laid heavy hands on Hunter, his health began to fail, and hence his transit to the field of war.

To join an army in the field is to enter the most intimate school of human nature. The most admirable features of man's character and the meanest are alike displayed. Unsuspected strength is revealed, long concealed weakness exposed, and in a year's campaign the events of a whole lifetime of ordinary existence may be passed through. Hunter entered this school at a turning-point in his career after two periods—the one of comparative idleness, the second of drudgery—and little doubt can exist as to both the sobering and inspiring effect it had upon his nature. As a result of his experiences he emerged a stronger and a better man, with a vastly wider outlook on the world, and doubtless capable of forming a juster estimate of his own powers and capacity to undertake the line of life for which he felt himself to be fitted.

The life of a military surgeon on active service, however, offers advantages beyond the mere acquisition of worldly wisdom and a knowledge of men. An army is not always fighting, and the surgeon, between periods of active and unceasing work, has intervals of quietude which are rare in any other path of professional life. Freedom from the cares of ordinary business and the manifold duties of practice allows uninterrupted opportunities for following out lines of thought and the prosecution of research. There can be no doubt Hunter utilised these opportunities to the utmost, for throughout his writings references are made to observations and investigations made during his period of service. He tells us, in fact, that his most comprehensive and complete contribution to scientific literature, the "Treatise on the Blood, Inflammation, and Gunshot Wounds," was the direct product of the experience gathered at that time. The long period which elapsed between the conception of the work and its publication is characteristic of Hunter's method—a method founded on the desire to complete his knowledge on any subject before submitting himself to public criticism.

A method desirable in itself, but when adopted by a man whose aims are of the scope of Hunter's, too often, as in his own case, robs the world of receiving the benefits of a wealth of critical observation and knowledge which passes together with its owner to the grave.

#### *Research in the Present War.*

While considering the opportunities of research his military life afforded to Hunter, one cannot help comparing them with those enjoyed by the present generation. During this campaign laboratories both of the clinical type and those fitted for more extensive research have been provided not only for the base hospitals but also in connexion with the casualty clearing stations which have performed so much of the duties of stationary hospitals near the front.

A number of active young observers have been engaged in research on every problem which the wounds and diseases of the soldiers have raised, and it may be confidently expected that a weighty harvest of new facts will have been garnered when opportunity arises for their collation and digestion. The pathological anatomy of the lesions produced by gunshot injury to the brain, the spinal cord, the lungs, heart, and the abdominal viscera has been worked out to an extent that will leave little to desire. New facts regarding cerebral localisation have been noted, while others founded on animal experiments alone have been confirmed by injuries comparable to the knife of the physiologist.

Observations regarding the fevers of the field have been accumulated, and enormous practical experience of the value of the protective inoculation for enteric fevers has been acquired, while the prophylactic value of tetanus antitoxin and its influence in modifying the character of a subsequent attack has been placed beyond the region of doubt.

It is not perhaps too much to expect that not only the acquisition of this extended knowledge, but also the manner of its acquisition, will exert an enduring influence upon the workers to whom we are indebted for it, and a resulting benefit will be conferred upon the community as a slight return for the misery and suffering which have been imposed upon the present generation. May we not hope that many of the workers may be influenced as John Hunter was and remain to the end of their careers active searchers after, and exponents of, the secrets of nature as well as better practitioners of medicine.

#### CONCLUSION.

Many of my predecessors have striven with a varying measure of success to portray Hunter as a man and member of society, yet the strange paucity of material at command appears to render any estimate of his personality from this point of view incomplete and uncertain. I prefer to ask my audience to study his presentment as it hangs upon the wall before us, and from its inspiration to try to form a true conception of the man and the soul that was within him.

The concrete labour of his hands is still exhibited within these walls, while the germs contained in his writings have served to incite and direct the minds of the many searchers in the wide field of biology who have followed in his footsteps. If but one lesson could be learned—the secret of his untiring industry—and this pressed home on those whose privilege it is to follow in his path great indeed might be the benefit to mankind. The problems that to-day await solution are no less numerous or less vital than those John Hunter sought to unravel, while the constantly increasing means of investigation at command lay a growing responsibility upon the student.

The memory of John Hunter is fresh within these walls, and it is still green without, and I cannot perhaps better close this unworthy effort to sustain that memory than by quoting the words of one of his bitterest foes regarding the period of Hunter's life immediately following his return from the wars.

"During this time he found himself at leisure for meditating plans of life that plainly denote an intrepidity of mind and a vigour of application which natural obstacles unsurmountable by most could not suppress in him; (plans) which few have attempted although supplied by the completest aid of early academic learning."<sup>13</sup>

Mr. President, posterity has judged how far Hunter succeeded in his aims, and has within the walls of this College awarded him a standing memorial which would, I think, have satisfied the man himself.

## An Address

ON

### NAVAL MEDICINE IN THE GREAT WAR.

*Delivered at the Medical Society of London  
on Feb. 12th, 1917,*

BY H. D. ROLLESTON, C.B., M.D.CANTAB.,  
F.R.C.P. LOND.,

TEMPORARY SURGEON-GENERAL, R.N.; CONSULTANT PHYSICIAN, ROYAL  
NAVY; SENIOR PHYSICIAN, ST. GEORGE'S HOSPITAL.

#### MEDICAL PERSONNEL.

MR. PRESIDENT AND GENTLEMEN.—At the outbreak of war the permanent Medical Service of the Navy, with Sir Arthur May as Medical Director-General, was at once expanded by the mobilisation of its retired members, of officers on the emergency list, and of the medical officers of the Royal Naval Volunteer Reserve. In addition, a large number of temporary surgeons were entered, and about ten consultants were appointed, mainly to the large base hospitals. A considerable proportion of the temporary surgeons first passed through the large naval hospitals and received some instruction in naval routine and procedure. Rather later an old type of naval medical officer—viz., allied to that of surgeon's mate—was revived in the appointment of unqualified medical students who had passed their examination in anatomy and physiology, under the title of Surgeon-Probationers, R.N.V.R. They were usually appointed in batches of 15 to Haslar, where they were instructed in Service routine, accounts and returns, victualling of the sick and treatment of wounded in action, and were subsequently drafted to destroyers, which ordinarily do not carry medical officers, and to other small sea-going ships, to render first-aid. After a certain period of service many of them were granted leave to prepare for and pass their final examinations, and so to become temporary surgeons.

The work of the clinical laboratories of the large base hospitals was assisted by the utilisation of men with laboratory knowledge but without medical qualifications, who, however, did not receive naval rank. Dr. P. Fildes was sent to Haslar by the Medical Research Committee and was of the greatest use in dealing with the bacteriological examination of the numerous convalescents from dysentery, enteric fever, and other intestinal diseases sent from Gallipoli.

Queen Alexandra's Royal Naval Nursing Service was more than trebled by the mobilisation of the reserve nursing sisters. The number of nursing sisters at the large base hospitals was thus very largely increased and they were supplied to the hospital ships, which usually carry four nursing sisters, two regulars and two reserves. The existing sick-berth staff, which was considerably depleted when the Fleet was mobilised, was supplemented by the Naval Auxiliary Sick Berth Reserve, composed mainly of men from the St. John Ambulance Brigade.

#### TRANSPORT OF THE WOUNDED AND SICK.

Transport duties are familiar to naval officers, and their services have naturally been utilised during the war. The naval transport, both at home and abroad, has been under the control of Surgeon-General Sir James Porter, K.C.B., who, early in 1915, went out to supervise the transport arrangements in Gallipoli for the Army as well as the Navy. Fresh developments in methods of transport, such as a new ambulance sling (Boydon), a monowheel stretcher-carrier (Rev. B. Close), the use of the movable-cot system on ambulance trains, and improvements on hospital ships have been evolved.

*Ambulance trains.*—Of the four naval ambulance trains in use at present in this country, the larger ones, made up of 12 coaches and carrying 120 cot cases, travel from the north to the south as occasion requires, in ordinary times about twice in ten days. Once a week they take the patients off the hospital ships, and rather less often they collect patients from the naval hospitals in the vicinity of the naval bases. The patients are dropped in succession at the large naval hospitals, Plymouth, Haslar, Chatham, and occasionally at Portland. These, colloquially called "round" trains, carry two medical officers, a crew of 36 stewards and sick-berth attendants,

but no female nurses. Two padded rooms are provided for the reception of lunatics. A small ambulance train of six coaches, called "the shuttle," travels locally between the naval bases and the local hospitals. Sir James Porter and Acting Staff-Surgeon A. V. Elder, R.N.V.R., devised a plan whereby the Service cot, into which the patient is placed in his own ship or in the hospital ship, is securely suspended and lashed up against the fender at the side of the coach in the ambulance train, thus avoiding the fatigue necessitated by transfer from a stretcher to a fixed cot in the ambulance train.

*Hospital ships.*—The experience of the present war has somewhat modified previous conceptions of the uses of hospital ships. In peace-time a hospital ship accompanies the Fleet and serves as a mobile base hospital until it becomes full, when she leaves the Fleet in order to discharge the patients to a land hospital, and for the time acts as a marine medical transport, or, in other words, a marine ambulance (Elder<sup>1</sup>). In the South African War (1899-1902), in the transport of wounded and sick across the Channel, and in the case of their service between the Mediterranean and this country at the present time, our hospital ships did, and now, act as "Marine Ambulances"; and in the Russo-Japanese War (1904-5) the two Japanese naval hospital ships worked on these lines. In modern naval engagements, contrary to what might have been anticipated,<sup>2</sup> the hospital ships cannot accompany the Fleet and take charge of the wounded for the following reasons: (1) the hospital ships could not keep up with the rapidly moving battleships; (2) the transfer of wounded from a battleship to the hospital ship would be possible only in exceptionally calm conditions; and (3) the transfer of wounded would oblige the battleship to have to, and thus expose it to hostile submarine attack. In order to meet this want it has been suggested that fast vessels of about 500 tons, registered under the Geneva Convention, and fitted with appliances for rapidly picking up survivors from the sea, should be employed on the scene of a recent action. But this plan has not been put into effect.

The use of hospital ships in war-time may, as Elder points out, be divided into: 1. The intervals between actions, during which the hospital ship remains at the naval base until it is full—for four or more weeks—and then discharges its patients, by steaming to a railhead, to an ambulance train. During its stay at the naval base the load of the hospital ship may be lightened from time to time, and its stay thus prolonged, by evacuation of some patients to a hospital carrier which conveys them to a land hospital or ambulance train. A large number of surgical operations are performed in a hospital ship during its stationary period at a naval base and minor cases when cured return to duty in the Fleet.

2. The post-action phase, when the hospital ships are collected at the naval bases to await the arrival of the battleships, receive the wounded, and serve as clearing stations. The wounded and burnt are sorted and as rapidly as possible evacuated to the shore and to the ambulance trains. Severe cases, which would obviously suffer from transport, are taken to the comparatively small hospitals in the immediate neighbourhood, but all suitable cases are at once despatched by the ambulance trains to the large base hospitals in the south of England, so as to clear the land hospitals in the vicinity of the naval bases for the reception of further instalments of wounded.

Immediately after a battle, therefore, a hospital ship ceases to act as a base hospital and becomes a clearing station, and should be evacuated as rapidly as possible, as their capacity for cot cases—on an average 250—does not admit of any extension. It should be added that a hospital ship may be employed as a permanent floating hospital for infectious diseases at a naval base which is remote from such hospitals on land.

Hospital ships, like ambulance trains, had to be brought into being when war broke out, and were provided by the transformation of liners. They were staffed by the existing executive crews of the company and by naval medical officers, with a Fleet-Surgeon in charge, and with nursing sisters.

<sup>2</sup> At the Battle of the Yellow Sea on August 10th, 1904, the Russian hospital ships followed their Fleet, and, as the Japanese point out, ran the risk of being accidentally torpedoed. (The Surgical and Medical History of the Naval War between Japan and Russia (1904-1905), 1911, pp. 121, 150.)

## THE HEALTH OF THE NAVY.

In considering this subject a distinction may conveniently be made between the health of (i.) the shore depôts and training establishments; (ii.) the Service afloat; and (iii.) the Royal Naval Division and the Marines serving on land.

I.—*The Shore Depôts and Training Establishments.*

The barracks, depôts, and training establishments are more exposed than the Service afloat to invasion by epidemic and other infections on account of their contact with the civilian population, the influx of new entries, and, especially in the case of the boy-training establishments, by the massing together of large numbers of youths who are more susceptible than adults to many of the common epidemic affections. Further, the health of the Fleet has been protected by the adoption of quarantine measures as regards drafts sent to it from the shore depôts. The liability of the shore establishments to epidemic disease is shown by the incidence of cerebro-spinal fever; out of 274 cases in the Navy during the first two years of the war, 252, or 92 per cent., occurred on shore; thus, there were 63 in the Portsmouth area, 58 in the Plymouth area (including 22 cases from boy-training ships), 42 at the Crystal Palace depôt, 39 in the Chatham area, 27 at the Deal depôt, and 18 at Shotley.<sup>3</sup> Shetlanders in barracks suffered much from measles, probably on account of the absence of any racial immunity to this disease.

II.—*The Service Afloat.*

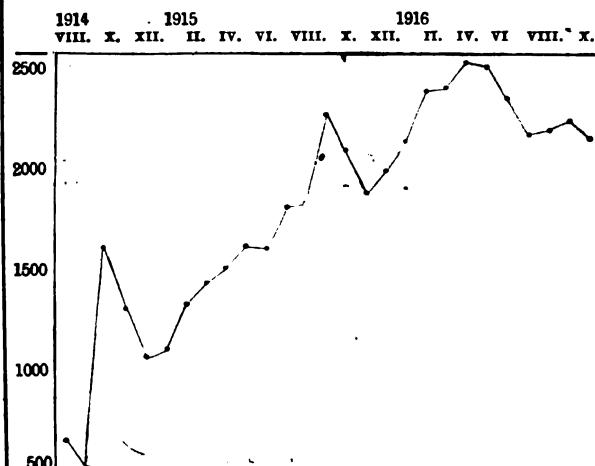

The health of the Fleet—our first line of defence—is of such paramount importance that it demands more detailed description. Under this heading reference will be made first to the Grand Fleet in home waters and then to the Mediterranean Fleet.

*The Grand Fleet.*—The general health of the Grand Fleet has been extremely good, indeed probably better than in times of peace. The average daily percentage of sick in the whole Fleet in 1913 was 2.37, and in 1914 a little lower, 2.03. Since the outset of war cases of sickness have naturally been sent off to hospital more rapidly than in peace time, and thus the daily sickness in the Fleet is diminished. But even allowing for this, the average daily sickness in the Grand Fleet has been extremely low, almost always under 1 per cent., and indeed has fallen since the outbreak of war. This percentage incidence would have been even less had it not been for the higher rate of sickness among the reservists and pensioners. Most of the sickness was of a minor character, such as seasonal influenza and boils.

*Infectious diseases.*—Measles, mumps, rubella, scarlet fever, and diphtheria occurred, but in the majority of instances they subsided after the appearance of the initial cases. An interesting point was the severity of measles among the Shetlanders both on the Fleet and among the reservists stationed at Lerwick, where there was a severe epidemic early in 1915 (McVittie). In ordinary times measles is rarely seen in the Shetlands, but when it is introduced an epidemic results. This severity of the disease in a race unprotected against it recalls the devastating epidemics of measles in the adjacent Faroe Islands in 1781 and 1846, in Fiji in 1875 and 1907, and in the neighbouring island of Rotuma in 1911 (Corney<sup>4</sup>). Dr. R. P. Heddle, medical officer of health of Kirkwall, writes that in some of the Orkneys measles is often absent for 15 or 20 years, and that when it occurs the children have it in much the same manner as in the south, but that adults take it severely and often suffer from pneumonia and occasionally from meningitis. I saw a relapse of measles in a Shetlander on the twenty-eighth day of the disease at Chatham—an extremely rare event. No case of small-pox occurred in the Fleet, thus showing the value of vaccination which has been compulsory in the Navy since about 1858. Except in the Mediterranean Fleet there were very few cases of enteric fever. Small outbreaks in three ships were traced respectively to infected oysters dredged up from Langstone Harbour, near Portsmouth, to a carrier, and probably to contaminated water taken on board at Montreal.

With the prolongation of the war it would naturally be expected that the amount of sickness would increase, and study of a curve showing the monthly average of officers and men in the large naval hospitals, Chatham, Haslar, Plymouth,

for the figures of which I am indebted to Surgeon-General D. T. Hoskyn, Surgeon-General G. Welch, and Surgeon-General W. H. Norman, shows that, allowing for two peaks due to extraneous causes (campaigns on land), there was a gradual rise from the beginning of the war until April, 1916, after which there came a slight fall. This would at first sight appear to confirm the anticipation of increased sickness. But, as already mentioned, the daily average percentage of sick in the Fleet had fallen during this period,

Graph of the monthly daily average of officers and men of all naval branches in the large naval hospitals at Chatham, Haslar, and Plymouth. The steep rise in October, 1914, was due to the admission of a large number of Belgian officers and men. The rise in September and October, 1915, was coincident with a large influx of patients from the Royal Naval Division on Gallipoli.

and it is therefore probable that the absolute increase of sickness, as shown by returns of the hospitals, is mainly due to the steady increase in the strength of the Navy during the progress of the war. Although there are, of course, no official figures obtainable as to the present strength of the Navy, it may well have so increased as to account for the doubling of the absolute number of sick, while the relative percentage incidence in the Grand Fleet has even fallen.

*The Mediterranean Fleet.*—In the Eastern Mediterranean squadron during August, October, and November, 1915, almost every ship was attacked by epidemic gastro-enteritis, which, however, died down in December. There was a fair number of cases of typhoid, paratyphoid, and dysentery between August and the end of December, 1915. The dysentery was mainly amoebic, and in many cases was associated with jaundice. The infection of these diseases was probably conveyed by flies and by men returning from the beach. The health of the Adriatic squadron at this time was excellent, and the average daily sickness for the whole Mediterranean Fleet from August 15th, 1915, to Oct. 31st, 1915, was 2.24 per cent., and from Nov. 1st, 1915, to Jan. 31st, 1916, 1.52. This compares favourably with a daily percentage of 2.37 sick for the whole Fleet in 1913. From Feb. 1st to April 30th, 1916, the health of the Fleet was even better with a daily percentage of 1. Between May 1st and July 31st, 1916, the daily average of sick was 1.14 per cent. A mild form of pyrexia (sand-fly fever) was prevalent at Salonika in May and appeared in some of the ships in the Eastern Mediterranean, and at intervals cases of paratyphoid, dysentery, and malaria occurred. In the quarter ending Oct. 31st, 1916, the daily percentage of sick was 1.08; dysentery and malaria were less frequent than in the previous three months, and typhoid and paratyphoid rare. No cases of beri-beri have been reported from the Mediterranean Fleet. For this information I am indebted to Sir A. May and his assistant, Fleet-Surgeon W. L. Martin, R.N.

During August and September, 1915, there was an extensive epidemic of dengue at Bermuda, and the average incidence of the disease in men of war there was 3 per cent. only. Meagher's<sup>5</sup> observations there support the view that the disease is spread by mosquitoes.

The good bill of health of the Fleet as a whole—a tribute to preventive medicine—is due to the following factors:

<sup>3</sup> THE LANCET, 1915, ii., 909; 1917, i., 54.  
<sup>4</sup> Corney: Proc. Roy. Soc. Med., 1913, vi. (Sect. Epidem.), 138.

<sup>5</sup> Meagher: Journ. Roy. Nav. Med. Service, 1916, ii., 188.

1. The comparative isolation of the fleets, and especially of the Grand Fleet, thus necessitating absence of venereal disease and of opportunities for alcoholic excess incident to the temptations of seaports. In the Fleet the men's daily allowance of stimulant is half a gill of rum, and special precautions are taken to prevent the adsorption of unused allowances by other men. 2. The quarantine precautions in drafting from the shore establishments to the Fleet, instituted by the Medical Director-General, Sir Arthur May. 3. The lectures given by the medical officers to the ships' crews on personal hygiene, dealing especially with the dangers of venereal disease and alcoholic excess. These lectures appealed to the common sense of the men, and as an illustration of their good effect it may be mentioned that on the return from leave of the men (about 1100) of one great battleship there were only three cases of gonorrhœa and one of syphilis. 4. Measures to obviate the effects of monotony entailed by awaiting events which have been long anticipated. Thus, when possible, regattas, boxing competitions, and other entertainments are got up, and both by their preparation and performance brighten up the men. In the Grand Fleet the short days of winter are the most trying, and then, in addition to entertainments, lectures, for example, by those who have made visits to the front in France, and cinema shows serve a useful purpose. Each big ship has its cinema, and there is a scheme of circulating films between the various ships. Periodical leave is also provided. 5. Improvement in the ventilation of the ships, due to the adoption in 1914 of the recommendations of a committee, of which Fleet-Surgeon R. C. Munday was the secretary, appointed in October, 1912, to consider the best methods of ventilating modern warships.

*Influence of mobilisation and war on the health of the navy.*—After this summary of the satisfactory state of the health of the Fleet a few words may be said as to the bad influence which mobilisation and war might be expected to exert on the health of the Navy. Large numbers, running into tens of thousands of men of the Royal Naval Volunteer Reserve, the Royal Naval Reserve, and the Fleet Reserve were called up and had necessarily to be rapidly passed into the ships during the first few days of the war, and as a result a certain proportion of unfit slipped through. The incidence of sickness was therefore naturally much higher in the Royal Naval Volunteer Reserve and Royal Naval Reserve than in the Royal Navy, which may be regarded as a picked body of healthy men. Cases of failure of cardiac compensation, of relapses in pulmonary tuberculosis, and of diseases which had previously led to discharge from the service were not infrequent, and dental caries and insufficiency extremely common. As cases of organic valvular disease of the heart are invalidated out of the service, malignant endocarditis, which usually supervenes on existing valvular disease, is a rare disease in peace time—averaging about two cases a year. Since the outbreak of war I have seen ten fatal cases (six examined post mortem) and one of that exceptional but allied condition malignant aortitis, chiefly but not entirely in reservists and pensioners.

In addition to the cases in the Navy a case occurred at Haslar of acute malignant endocarditis in a Belgian soldier who was for months under treatment for severe burns; after being normal for a long time the temperature suddenly shot up and the patient died in 12 days with, as the necropsy proved, acute malignant endocarditis. The interest of the case is that the onset and duration of the disease could be accurately determined.

The numerous new entries, mostly quite young, who are exposed to the depressing conditions incident to their change of life, such as vaccination, the fatigue of unaccustomed drills, and homesickness, provide a favourable soil for the occurrence of infectious diseases, such as measles, rubella, scarlet fever, mumps, and cerebro-spinal fever. Outbreaks of infectious diseases occurred, but it is remarkable that there was not more illness.

The effect of long-continued strain on men, especially pensioners and reservists, in activating latent disease, such as tuberculosis or heart disease, was naturally seen. In the Navy these two conditions lead to invaliding, and their recrudescence was therefore more frequent among reservists and pensioners called up for the duration of the war. Pulmonary tuberculosis in ships was not so frequent as some anticipated from the conditions necessitated by the war

strain, physical and mental, precipitated tabes dorsalis and general paralysis of the insane in some syphilitic subjects; and a generous view from the pension aspect has been adopted by the Admiralty. Some cases of incipient tabes have been utilised by work of a less arduous physical character. During the siege of Paris in 1870 it was noted that exophthalmic goitre became more frequent, and this has appeared to me to be true, both during the Boer War and the present campaign. Much discussion has taken place as to the influence of hyperthyroidism in the etiology of the so-called soldier's heart. Over-excitation of the ductless glands may result from excitement or from toxæmia due to acute infections; and Hurst<sup>6</sup> points out that as over-activity of the thyroid can be more easily recognised than that of the other ductless glands the resulting condition has been regarded as simple hyperthyroidism, but that the change is more complex, being really a disturbance in the activity of all the ductless glands. Diabetes mellitus, the incidence of which might conceivably be favoured by nervous strain, does not appear to me to have become unduly frequent.

The prolonged and monotonous strain necessitated by life in the Fleet favours mental deterioration, psychasthenia, and neurasthenia, especially in those with a neurotic taint and in those who have not been through a long training. Further, the short interludes of acute stress and excitement which punctuate the periods of monotonous alertness may so disturb the already vibrating balance as to precipitate an acute breakdown with violent though transient symptoms and delusions. The burden of responsibility and in a small ship the influence of comparative isolation on the senior officer favour mental instability, and may lead to a want of self-confidence bred of brain-fag. In an interesting psychological study of the influence of periods of (1) monotonous watchfulness, (2) acute stress, and (3) comparative calm on a ship's company during the first six months of the war, Beaton<sup>7</sup> found that mental troubles of a really serious nature occurred in less than 1 per cent. and mild neurasthenic conditions in less than 4 per cent. With the prolongation of the war the results of the continued and monotonous strain would naturally be expected to become more noticeable, but, as far as my impression goes, not to anything like the extent that would have been expected. This happy result is no doubt due to several factors—the fine spirit of confident superiority in the men, and the hygienic measures already mentioned. The effect of good moral in preventing mental disturbance was seen by the freedom of the men from these manifestations after the Jutland Battle.

*Casualties during action.*—With this subject I can attempt to deal in very brief and imperfect outline only. As compared with land warfare, the large number of men killed outright in naval actions is striking. In the Russo-Japanese naval war of 1904–05 there were 3692 killed and wounded, of whom 1883 were killed outright (including 1388 probably drowned<sup>8</sup>). It is not considered advisable in the public interest to give the figures for the Battle of Jutland, but from the total loss of battleships the numbers of men presumed to be drowned, though, of course, many in the sunk ships may have been killed, wounded, or burnt, must obviously have been very large.

*Wounds.*—As compared with wounds in the trenches, where the clothing and skin are ingrained with filth, wounds in naval actions obviously differ, and have been classed with those of severe machinery accidents. Wounds of soft parts and compound fractures were due to shells, their splinters, shrapnel, and fragments of the ship's structures. Several cases of eye injuries necessitated enucleation, and in one remarkable instance an eye was found to contain a piece of bone  $\frac{1}{2}$  inch square, apparently from the vault of another man's skull (L. Fraser<sup>9</sup>). The treatment of wounds by new antiseptic applications has been advocated by Sir Watson Cheyne (borsal), who also investigated Dakin's antiseptic, and a green spray of perchloride of mercury and malachite green (Fildes, Rajchman, and Cheattle<sup>10</sup>) has been used with success at Haslar. The rival claims of the antiseptic method and of the physiological hypertonic salt solution treatment have led to an

<sup>10</sup> THE LANCET, 1915, II., 165.

encounter between the President of the Royal College of Surgeons and Sir Almroth Wright.

*Burns* form an important proportion—at least a third—of the casualties in action, and fall into two main categories: 1. General and severe burns due to the ignition of our own cordite or to burning furniture. As the result of prolonged exposure to these flames destruction of the tissues is deep, the immediate mortality high, and sepsis and deformity especially prone to occur. 2. Burns of the exposed skin of the face and hands due to the momentary flash of high-explosive shells in a confined space. The flash is of such short duration that from instinctive closure the eyes escape, and the thinnest covering, provided it is not inflammable, almost completely protects the skin (Muir<sup>11</sup>). In the *Lion* about half the wounded had burns of the face and hands alone (Maclean and Stephens<sup>12</sup>). There seems to have been a general agreement that the Service picric-acid dressing was most efficacious as a first application, but subsequently moist and mild antiseptics were found to be more suitable. The new treatment by ambrine is now officially provided.<sup>13</sup>

Shock, even in cases of slight injury, was found to be excessive, and for this reason immediate operations should be avoided (Muir). As a means of obviating shock morphine proved a sheet-anchor,  $\frac{1}{2}$  to  $\frac{3}{4}$  grain being injected hypodermically. The sublingual method of allowing tablets to dissolve under the tongue, which is convenient as it does not necessitate the presence of a medical officer—the tablets being served out by an executive officer—was not satisfactory. The administration of  $\frac{1}{4}$  pint of warm bovril containing 2 oz. of brandy proved beneficial in the *Tiger* in the Jutland Battle.

*Poisoning by gases from explosives.*—The detonation of shells such as lyddite and the burning of our own cordite liberate large quantities of CO and CO<sub>2</sub>, but the most powerful factor in the production of "gassing" is nitric oxide. The symptoms usually come on after a comparatively uneventful interval; and possibly during this incubation period the NO and NO<sub>2</sub> are oxidised into nitric acid (Symons<sup>14</sup>), which accounts for the acute irritant effects on the respiratory tract. Severe headache and vomiting are early symptoms, followed by cough, husky voice, dyspnoea and cyanosis which become progressively worse, rapid respirations reaching 80 or more per minute, restlessness, pain and tightness behind the sternum, orthopnoea, frothy, sometimes blood-stained expectoration, and oedema of the lungs. Prophylactic treatment is most important and quite effective; it consists in the immediate application of the Service respirator containing cotton-waste soaked in the usual soda solution. The respirator should be worn round the neck from the beginning of the action, so as to lose no time in putting it in position. The treatment of the declared condition is unsatisfactory. Though theoretically attractive, atropine does not appear to have been successful. Some benefit has been ascribed to brandy, the production of vomiting, and the repeated administration of spiritus ammonia aromatus in 1 oz. of water.

Cases of carbon monoxide poisoning occurred, and I had the opportunity of seeing three cases among men employed in putting out a fire in the bunkers of a collier. One of these presented curious nervous symptoms, resembling in some respects peripheral neuritis but more probably functional in nature, which persisted for two years.

Delayed pneumonia after immersion was noticed by Deputy Surgeon-General H. W. G. Doyne in some cases after the sinking of the *Cressy*, *Pathfinder*, and *Hermit*. Pneumonia occurred about three weeks after the immersion.

Appendicitis is not rare in the Navy in peace-time; before the war it occurred in about 0·2 per cent. of the personnel of the Navy. Since the war began it is impossible to give the percentage, but it is by no means uncommon. I am indebted to Surgeon C. J. G. Taylor, R.N.V.R., for figures which show a decided percentage increase in the incidence of appendicitis directly after the Battle of Jutland among the sick from the engaged ships. He also points out that there was a similar rise in the incidence of appendicitis directly after a sweep of the Fleet in the North Sea when contact with the German Fleet was almost established. On the other hand, when the Hospital Ship *Soudan*, in which

he served, was present at the opening stages of the Gallipoli operations, and the men were exposed to conditions of naval warfare, the incidence of appendicitis among 11,619 cases of wounds, sickness, and accident was low—viz., 0·2 per cent.

### III.—*The Royal Naval Division.*

The Royal Naval Division served in Belgium, Gallipoli, and is now in France under the Army. The Marines also fought on land in Mesopotamia. The naval forces have therefore been exposed to the same infections and diseases as the armies with whom they have been associated. The contrast between the incidence of disease in the Service afloat and the Naval Divisions on land is as striking as that between the conditions of naval and military warfare generally. Even if statistics were available, it would be impossible to deal fully with the diseases among the Naval Division in Gallipoli, as this would be equivalent to a consideration of military medicine, but a few points of interest may be mentioned.

As has always been the experience in war until quite recently, diseases due to infection through the alimentary canal—diarrhoea, typhoid, paratyphoid, dysentery, and jaundice—levied a heavy toll in Gallipoli, and a large number of men were invalided to this country.

Diarrhoea was so frequent that it was regarded as an incident rather than a cause of going sick, and a solid motion was the exception rather than the rule on the Peninsula; men might go to the latrines ten times daily for months without reporting themselves as sick. As it was common when sand-storms were prevalent, it was called sand diarrhoea, but it is probable that it was not entirely due to the purely mechanical irritation of the sand, but that the sand conveyed micro-organisms into the food, and that flies, which were a veritable plague at Gallipoli, may have played a carrier part in the infection of food.

Dysentery, the amoebic and bacillary forms being predominant at different periods, claimed many victims, but the treatment by emetine and antidysenteric serum gave very satisfactory results. Indeed, many cases of amoebic dysentery appeared to have been cured by the time they arrived in this country, and thus amoebic dysentery appeared, as judged by the observations in this country, to be less common than it was reported to be in the Eastern Mediterranean. Among 143 cases in 1916 in which Mr. H. A. Baylis found protozoa in the faeces, 29, or 20 per cent., showed *Entamoeba histolytica*. Emetine was freely given, and in some instances the question arose whether subsequent palpitation, breathlessness, arrhythmia, and precordial pain were due to the poisonous effects of the acute infection, excessive smoking, or the remedy emetine; for experimentally emetine has been found to produce ventricular fibrillation (Levy and Rowntree). It is interesting to note other bad effects of this successful drug—peripheral neuritis and chronic diarrhoea with or without blood which must be distinguished from a recurrence of dysentery. On the other hand, the freedom with which emetine was given may have been responsible for the rarity of hepatic abscess. Three cases of entamoebae in the urine with temporary vesical irritation, possibly due to rupture of a small pericolic amoebic abscess into the bladder, came under my notice. Urinary amoebiasis has apparently seldom been observed, as Scott Macfie<sup>15</sup> refers to 15 cases only.

Bacillary dysentery as judged by a series of late convalescent cases examined serologically by Dr. P. Fildes was found to be more often—in the proportion of 8 to 1—due to Flexner's bacillus than to Shiga's. This seems to be contrary to the general experience in Gallipoli, but the conditions of the acute infection in which the bacilli can be isolated from the faeces and of late convalescence when the agglutination reactions were performed are not really comparable. The diagnosis with which patients arrived in this country was often changed as the result of laboratory examination, and sometimes mixed infections were discovered. Among 481 cases which gave positive agglutinations pointing to bacillary infections of the alimentary canal examined at Haslar, some of which were multiple, Dr. Fildes found that 30 per cent. were due to *B. typhosus*, 23 per cent. to *B. paratyphosus A*, 20 per cent. to *B. paratyphosus B*, 22 per cent. to *B. dysenteriae* Flexner, and 0·3 to *B. dysenteriae* Shiga.

<sup>15</sup> Scott Macfie: Ann. Trop. Med. and Parasit., Liverpool, 1916, x., 291.

A large number of patients were invalidated home with intestinal symptoms clinically described as paratyphoid or dysentery which, however, could not be serologically or bacteriologically proved to be due to any known infection, and were therefore labelled by the non-committal term of "enteritis." The antityphoid inoculation was fully justified by results.<sup>16</sup> Much bacteriological work was necessitated in the testing of patients sent home for intestinal diseases in order to prevent the escape of carriers into the general population. The increase in the number of patients in the large naval hospitals due to this cause is shown by the peak on the chart during September and October, 1915.

Epidemic jaundice, apparently imported from Egypt, was very common in Gallipoli at the end of 1915. The degree of the jaundice did not run parallel with the malaise, for men considerably bronzed continued at work while others with but slight icterus were obliged to go sick. Its etiology gave rise to much discussion ; from the freedom of many patients from preceding gastro-enteritis (McBean Ross,<sup>17</sup> Hurst<sup>18</sup>) it seemed unlikely that it was catarrhal jaundice in an epidemic form. Similarly there was no evidence that it was due to dysentery or enteric fever. In some instances it followed these diseases, but usually after an interval as an accidental event. I have seen it develop in England in convalescent dysenteric and typhoid patients. The suggestion that it was due to paratyphoid (*B. paratyphosus dardanensis*) infection of the biliary system has not been substantiated. Hurst regards the disease as an acute infection of the duodenum by an organism allied to *B. paratyphosus A*, which should therefore be treated with the same precautions as enteric fever. The only necropsy that I have seen showed severe gastro-enteritis with a plug of tenacious mucus in the orifice of the biliary papilla. Dilatation of the heart was a definite feature, and peripheral neuritis (beri-beri) was noted as a not infrequent sequel. In one case under my care glycosuria followed the jaundice.

A form of peripheral neuritis identical with beri-beri in its clinical aspects occurred in Gallipoli and in Mesopotamia ; 12 cases of beri-beri were treated at the Royal Naval Hospital, Plymouth, in 1915-16, and at least 15 such cases at Haslar during the same period. In this outbreak the usual etiological explanation of beri-beri—namely, the absence of the specific vitaminine—presented difficulties ; but Wilcox,<sup>19</sup> who recognised that jaundice often preceded this beri-beri, supported the deficiency hypothesis of the disease by the explanation that the diet suitable for jaundice, diarrhoea, dysentery, and paratyphoid fever contains extremely little, and that tinned food is almost entirely devoid of the anti-beri-beri vitaminine which is destroyed by a temperature of 130° C. An ingenious hypothesis was put forward by A. F. Hurst, who revived Hamilton Wright's view that beri-beri is the result of a specific infection of the duodenum, the toxins produced by which exert a special action on the nervous system. As the epidemic jaundice in Gallipoli was regarded as the result of such a duodenitis, which, however, did not always obstruct the common bile-duct, the occurrence of this beri-beri-like neuritis after jaundice, or even without previous icterus, can be thus explained, and the necessity of relying entirely on a deficiency in vitaminines in the food is no longer binding. The dilatation of the heart and dropsy, which were marked features of some cases of beri-beri seen in Haslar, can thus be correlated with the dilated heart described in the epidemic jaundice.

Other fevers occurred in Gallipoli and Salonika, such as malaria, which was recently prevalent among the Royal Naval Air Service at Thasos and Cassandra in the autumn of 1916, both the forms of trench fever, and sand-fly fever. The value of anti-choleraic inoculation and of the efforts of the Health Department at the Dardanelles was shown by the freedom of the Royal Naval Division from cholera and plague, which Dr-puty Surgeon-General O. W. Andrews tells me were prevalent among the Turks in the immediate neighbourhood.

War nephritis and trench or Gallipoli sore, apparently analogous to the veldt sore in the South African War, and

due to a Gram-positive diplococcus (Archibald, Hadfield, Logan, and Campbell<sup>20</sup>), were also reported.

A considerable number of bullet wounds of the chest with resulting haemothorax were under observation at Haslar during the early part of the war, and as a rule were watched and not explored unless there was definite evidence of an embarrassing large infusion or of infection, and, though recovery was slow, the vast majority did well. This was in accordance with Makins's advice based on experience in the Boer War. In the present war the practice in the Army has been to tap sterile haemothorax except when small, and this course has not led to infection and has hastened recovery. In the trenches infection of a chest wound is much more prone to occur than was the case on the relatively sterile veldt.

#### DISEASES OF AIRMEN.

The chapter of aeroplane injuries and diseases—which from its interest may be briefly mentioned here—has been begun by Staff-Surgeon H. V. Wells.<sup>21</sup> From leakage of petrol spray the pilot may become dizzy, and the exhaust gases from the engine—carbon monoxide and dioxide—may cause headache, drowsiness, and malaise. The rarefied atmosphere at great elevations may induce the symptoms well known in balloonists, and Wells refers to a case of frost-bite in an airman who had been exposed to 34° of frost at an elevation of 15,000 feet. Psychasthenic symptoms—namely, loss of self-confidence and the resulting mental worry (aerothenia)—are not uncommon, and prove that the victim has mistaken his sphere of activity. Flying is undoubtedly the job of a young man under 30 years of age, and not every young man is temperamentally or physically fitted to carry it through. Perfect eyesight is necessary to ensure safe landing, correction with glasses being not without its dangers ; perfect hearing is essential to detect the first indications of engine defect, and free movement of the joints of the lower limbs to control the steering-gear. Fits and tendency to faint absolutely deter the aspirant from the air service. In one remarkable instance at Haslar an airman who fainted, with the result that the aeroplane dived nose downwards 1200 feet into a ploughed field, escaped with such minor injuries that he was at first extremely loth to give up this branch of the service.

#### ON THE PASSIVE IMMUNITY CONFERRED BY A PROPHYLACTIC DOSE OF ANTI- TETANIC SERUM.

BY A. T. MACCONKEY, M.B., B.C. CANTAB., D.P.H. ;  
AND  
ANNIE HOMER.

THE occurrence of cases of tetanus even though a prophylactic injection of serum has been given draws attention to the comparatively short duration of the complete passive immunity conferred by a dose of antitoxin. There are many references to this in the literature from 1893 (Roux and Vaillard) down to the present time (Vaillard, 1916), and yet this fact does not seem to be as fully recognised as it ought to be even now.

It has been stated that after a subcutaneous injection of antitoxin the antitoxin content of the blood reaches its maximum in 2-3 days and then remains fairly constant till about the seventh day, when it begins to decrease. It is also said that a sufficient dose of antitoxin gives complete protection for several days and partial protection for 2-3 weeks. The object of the following communication is to record some experiments which bear on this point. These experiments form part of a larger series which was undertaken with the object of ascertaining the most economical, and at the same time reliable, method of using tetanus antitoxin.

Our first object was to find out the smallest quantity of antitoxin which would give complete protection for one week. For this purpose several series of guinea-pigs were taken and each animal in a series received a subcutaneous injection of the same amount of antitoxin, but the number

<sup>16</sup> Vide Bassett Smith : Journ. Roy. Nav. Med. Service, 1917, III., 30.

<sup>17</sup> McBean Ross : Ibid., 1916, II., 317.

<sup>18</sup> Hurst, A. F. : Medical Diseases of the War, p. 104. 1917.

<sup>19</sup> Wilcox : Journ. Roy. Army Med. Corps, 1916, xxvii., 191 ; and THE LANCET, 1916, I., 566.

<sup>20</sup> Archibald, Hadfield, Logan, and Campbell : Journ. Roy. Army Med. Corps, 1916, xxvi., 695.

<sup>21</sup> Wells, H. V. : Journ. Roy. Nav. Med. Service, London, 1916, II., 65-71.

of units given to each series was different. Seven days later the immunised animals and a series of controls received an injection of tetanus toxin subcutaneously. The experiment was repeated until the results were quite clear, as may be seen in Table I.

Note.—To avoid repetition it may be stated that all injections were given subcutaneously in the abdominal region.

TABLE I.

Dose of toxin (U.S.A.)	Anti-toxin units.			Controls.			Anti-toxin units.			Controls.		
	3 $\frac{1}{2}$	7	10 $\frac{1}{2}$	3 $\frac{1}{2}$	7	10 $\frac{1}{2}$	1	2	3	4	5	6
0·000002 g	N	N	N	SI								
0·000003 g	M	N	N	..	Tet.*	..	N	N	..	N	N	..
0·000004 g	..	..	..		+4	..	+5	..		SI	SI	..
0·000005 g	..	..	..	Mi	..	..	+4	..	+12	..	Mo	..
0·000006 g	..	..	..	..	+4	..	+3	..	Mi	N	Tr	..
0·000007 g	..	..	..	..	+3	..	+3	..	SI	..	+4-5	

\* Tetanus, but recovered. N = Nil (no symptoms of tetanus). SI = Slight attack of tetanus. Mi = Mild attack. Mo = Moderate attack. Tr = trace. + = Death, and the number which follows indicates the day on which death occurred. Two numbers (4-5) refer to the night between two days.

We see that  $\frac{1}{2}$ , or  $\frac{1}{3}$  U.S.A. unit does not afford complete protection for one week, though these amounts saved life against a dose of toxin which was fatal to the controls. If, however, we give 1 unit or more we obtain complete immunity during at least one week. As an ordinary man is about 220 times heavier than these guinea-pigs, this would mean that, calculating by body-weight only, a man would require some 250 U.S.A. units to protect him for a week, while a dose of 500 U.S.A. units would allow for man being twice as susceptible as the guinea-pig.

It might be urged that the conditions of the experiment were not similar to those occurring in actual practice. In order to meet this objection an experiment was carried out in which each animal received a small dose of toxin some time before the serum and then further small doses of toxin at short intervals, until by the seventh day each animal had received a lethal dose of toxin (0·000006 g.). The results are shown in Table II.

TABLE II.

No. of animal.	Days—						Result.
	1	2	3	4	5	6	
1-5	0·000001g toxin	3 units of antitoxin	..	0·000001g toxin	..	0·000004g toxin	N
6-10	0·000001g toxin	10 A.M. 3 P.M. 6 units of toxin	0·000001g toxin	0·000001g toxin	0·000002g toxin	..	N
11-15	0·000001g toxin	9 units of toxin	0·000001g toxin	0·000001g toxin	0·000002g toxin	..	N

N = Nil (no symptoms of tetanus).

It is obvious that giving part of the toxin (1/6 of a lethal dose) before the serum has made no difference to the result.

If we increase the interval between antitoxin and toxin from 1 week to 10 days we find that the immunity is beginning to diminish, and if we wait 2 weeks before testing the immunity we obtain results which confirm those of previous observers and which show that most of the protection afforded by an injection of antitoxin has disappeared. There may, however, be a partial immunity sufficient to save life, though not to prevent an attack of tetanus. (Table III.)

TABLE III.—Immunity after 10 Days.

Dose of toxin.	Dose of antitoxin in units.				Controls.
	1	3	6	9	
0·000004 g	Trace for 4 days.	Nil.	Nil.	Nil.	Mild tet., recd., +5-6
0·000005 g	Nil.	S.L.T. for 3 days.	..	..	"
0·000006 g	S.L.T. for 1 week.	Mild tetanus.	+7-8 about 1 week.	S.L.T. for about 1 week.	"
0·000007 g					..

S.L.T. = slight local tetanus.

TABLE IV.—Immunity after 2 Weeks.

Dose of toxin.	Antitoxin units.			Controls.	Antitoxin units.			Controls.
	3 $\frac{1}{2}$	7	10 $\frac{1}{2}$		3	6	9	
0·000003 g	—	Slight.	Mild.	Slight.	—	..	..	K 13*
0·000004 g	+7	+8	+6	+6-7	Trace	+8-9	Mod.	..
0·000005 g	+7	Trace.	Slight.	+6-7	..	+7	..	+6
0·000006 g	Trace	..	+6	+6-7	K 5*	..	..	..
0·000007 g	Mild.	..	+8	Mod.	Trace	Slight.	..	+4-5

\* K 5 and K 13 = killed on fifth and thirteenth day respectively because of severity of the attack.

When the immunity has diminished so much in the course of a fortnight after an injection of tetanus antitoxin one is not surprised to find that practically all is gone at the end of three weeks.

TABLE V.—Immunity after 3 Weeks.

Dose of toxin.	Number of units of antitoxin.				Controls.
	1	3	6	9	
0·000004 g	+ 6-6	+ 7-8	Mod. tet. recd.	+ 8-9	Mod. tet. recd.
0·000005 g	+ 4-5	+ 4	+ 4-5	Mod. tet. recd.	+ 8-9
0·000006 g	+ 11-12	+ 4-5	+ 5	+ 5-6	
0·000007 g	+ 4	+ 3-4	+ 4-5	+ 5-6	+ ..

From these results it would seem that the increased dose of antitoxin has not had an appreciable effect in increasing the duration of the subsequent immunity.

In view of these results it seemed advisable to try whether a very much larger dose than had so far been given would give a correspondingly better result. Each of 5 guinea-pigs received beneath the skin of the abdomen 40 U.S.A. units of tetanus antitoxin, and after an interval of 2 weeks the test doses of toxin. (Table VI.)

TABLE VI.—Immunity 2 Weeks after 40 U.S.A. Units of Antitoxin.

Antitoxin.	Toxin.	Result.
40 U.S.A. units.	0·000003 g	No symptoms of tetanus.
"	0·000004 g	Mild tetanus from 5th to about 15th day.
"	0·000005 g	Trace of local tetanus 8th-16th day.
"	0·000006 g	"
"	0·000007 g	Mild tetanus from 7th to about 20th day

We see, then, that even such a large dose as 40 U.S.A. units (corresponding to at least 8000 units in man) does not afford complete protection for a fortnight. It would also seem that Levin (1909) was right when he expressed the opinion that we cannot hope by increasing the dose of antitoxin to increase greatly the duration of passive immunity.

These results led us to go a step further and to give an enormous dose, a dose which would allow us to compare our results with those of Ruediger (1913), who stated that 250 U.S.A. units of tetanus antitoxin would protect guinea-pigs for from four to six weeks against a dose fatal to the controls. Unfortunately, he does not mention whether the protection was complete or not. We gave to each of a series of guinea-pigs 250 U.S.A. units of antitoxin and tested their immunity at the end of four weeks. (Table VII.)

TABLE VII.—Immunity 4 Weeks After 250 Units of Antitoxin.

Antitoxin.	Toxin.	Result.
250 U.S.A. units.	0·000006 g	Mild tetanus—well within 3 weeks.
"	"	Moderate " — " "
"	"	" Slight symptoms. "
"	"	Mild attack—well within 3 weeks.

This large dose has protected, but not completely, though there was never any question of life being endangered. Now there happened to be available 13 guinea-pigs which had each received 10 c.c. of antitetanic serum in the ordinary course of routine testing. To each of these animals was given beneath the skin of the abdomen the official minimal lethal dose of the standard dry powdered test toxin which has been used in all the (previous) tests detailed in the paper. (Table VIII.)

A consideration of the results of these experiments fixes our attention on two points which stand out prominently.

The one is the extreme differences in the susceptibility of guinea-pigs to tetanus toxin; the other is the enormous doses which apparently we must give when we aim at obtaining passive immunity of long duration. Of course, it

TABLE VIII.

No.	Anti-toxin.	Interval between injection of antitoxin and of toxin	Toxin.	Result.
	U.S.A. units.	Days.	0·00000·6 g.	No symptoms of tetanus.
1	9000	27	"	Trace of "tetanus" present from 3rd-6th day and then passed off.
2	3000	27	"	Very slight symptoms; recovery.
3	3000	27	"	Very slight "tetanus. Death 21st day.
4	2200	31	"	Tetanus. Death 6th day.
5	2200	31	"	Slight "tetanus; recovery.
6	3000	40	"	Mild "tetanus; recovery.
7	3000	40	"	Only a trace; recovery.
8	3500	47	"	No symptoms.
9	3500	47	"	
10	3500	40	"	
11	3500	40	"	
12	3000	28	"	
13	3000	28	"	

would, in present circumstances, be quite impracticable to use for man doses corresponding to some of those we have given to guinea-pigs, and we must content ourselves with the smaller doses, even though the protection does not last as long as we would wish.

We have now to decide upon what is the best thing to do, knowing that we cannot count upon producing an immunity of long duration by the use of a single prophylactic dose of tetanus antitoxin. There are two ways of dealing with this question. On the one hand, we might, after giving the prophylactic dose, simply keep very careful watch for the first signs of incipient tetanus and then at once treat the case energetically. We have not noticed in the literature any suggestion that this course should be followed, though it is possible that as our knowledge of the disease and its early symptoms increases, it may turn out to be after all the best practice. On the other hand, we may repeat the protective dose with the object of keeping up the immunity. There is in favour of this latter view a large volume of opinion, much of it recent and based on experience gained since the war began.

Park and Williams (1914, p. 331) say that where tetanus infection is suspected the antitoxic serum should be given a second, or even third, time at intervals of seven days. V. Behring (1914) considers that if the infection of the wound continues the prophylactic dose should be repeated and antitoxin might also be injected locally.

Teutschländer (1915) goes so far as to recommend that as long as there may be tetanus bacilli in the body, then if thorough surgical treatment with removal of all foreign bodies—including their capsules when encapsulated—cannot be carried out, a curative dose of serum should be given whenever the temperature rises or there is any suspicious change in the condition.

Bazy (1916) is in favour of repeating the injections every eight days for a month. Among others who express opinions similar to the above may be mentioned Dubs (1915), Witzel (1915), Fraenkel (1915), Aschoff (1915), H. E. Robertson (1916), Kümmell (1916), Bérard and Lumière (1916), Montais (1916), and Capitan (1916).

Finally, we may quote from a communication made by M. Vaillard to the Academy of Medicine, Paris, on Sept. 5th, 1916, in which he says:—

"..... le Sous-Secrétaire d'Etat au Service de Santé a bien voulu me confier, de concert avec notre collègue M. Roux, l'examen des observations recueillies, pour en déduire les enseignements qu'elles comportent sur la prévention du tétonos. Les considérations présentées à la suite de cet examen lui ont inspiré une instruction en date 10 Juin, 1916; j'ai cru devoir les communiquer à l'Académie."

He mentions that the passive immunity conferred by a dose of antitoxin lasts only about 8-12 days, and that if toxin is still being produced in the body after this lapse of time there will be no antitoxin present to neutralise it, and then:—

"Si on contrarie la provision d'antitoxine est renouvelée en temps opportun, la préservation sera prorogée pour un nouveau laps de temps après chaque nouvelle injection. De là, pour certaines blessures particulièrement dangereuses, l'absolue nécessité de ne pas confier l'immunisation à une

seule injection préventive, et de réitérer ces injections tant que persiste la menace du foyer infecté d'où peut sortir le tétonos."

He then goes on to speak of late tetanus, and concludes:—

"De ces considérations on est conduit à déduire que les réinjections méthodiques de serum antitoxique fourniront un des moyens de mieux assurer la prévention du tétonos consécutif aux blessures récentes et d'étendre le même bénéfice aux périodes plus ou moins éloignées de l'évolution des plaies. Il serait regrettable que la crainte de l'anaphylaxie dont la survenance a été exagérée surtout à la suite des injections sous-cutanées détournât les chirurgiens d'une pratique judicieuse qui a fait ses preuves."

This question of anaphylaxis was brought prominently forward by M. de Massary before the Société Médicale des Hôpitaux de Paris in October, 1915, when he referred to the case of a soldier who was wounded and received an injection of serum. Wounded again a month later, he told the surgeon of the previous injection. Owing apparently to fear of anaphylaxis a second dose of antitoxin was not given. Five days later tetanus supervened and ended fatally.

The discussion which followed this communication ended in the appointment of a committee to inquire into the question of the effect of reinjections of serum. The committee was composed of MM. Achard, Aviragnat, Barbier, Chantemesse, Marfan, Netter, Siredey, and Louis Martin, who, after very careful consideration of the subject, drew up a report which was published in the *Bull. Société Méd. des Hôpitaux de Paris*, Nov. 19th, 1915, p. 1076, and which may be summarised as follows:—

They define a "reinjection" of serum as any injection which is made not earlier than 15 days after the previous injection.

*Intravenous reinjections*, they consider, should not be used as a routine measure, but be limited to cases of plague and grave tetanus, and above everything the injection should be made very slowly so that it can be stopped if necessary before much has been given.

Of *intraspinal reinjections* they say that it is impossible to give indications or contra-indications, for it is a surprising fact that in the same patient these injections are sometimes well borne and sometimes give rise to anxiety. The serum should be run in very, very slowly, and the needle left *in situ* for a time so that, should any disquieting symptoms occur, as much fluid as is necessary may be allowed to flow out again. When all fear of trouble is over the needle may be removed.

*Subcutaneous reinjections* are rarely followed by grave symptoms, and the risk of their occurrence cannot be compared with the risks run by the patient if a reinjection is not made. When there is urgent need for it the reinjection of serum should never be omitted owing to the fear of anaphylactic trouble.

Reinjections should not be given after a meal during the period of digestion, and should be given where the cellular tissue is very lax. They should be given slowly and stopped at the first sign of trouble. One should be doubly careful in the case of tuberculous subjects, asthmatics, those subject to urticaria, hay fever, or who are affected by various scents (e.g., smell of horses), or where there is any suspicion of purpura. In such conditions one should proceed very slowly with the first portions of the injection, one should stop at the slightest sign of anaphylaxis, and then, if all is well, begin again an hour or so later.

The final conclusion of the committee is that:—"Ou ne peut, dans aucun cas, reprocher à un médecin d'avoir pratiqué une réinjection de serum dans un but prophylactique ou thérapeutique."

### A CLINICAL AGGLUTINOMETER:

AN APPARATUS FOR USE AT THE BEDSIDE OR IN THE LABORATORY FOR MAKING RAPID ESTIMATIONS OF THE AGGLUTININ TITRE OF THE BLOOD.

BY R. P. GARROW, M.D. ABERD., D.P.H.,  
CAPTAIN, R.A.M.C.

(Report to the Medical Research Committee.)

In the *Archives of Internal Medicine*, Dec 15th, 1910, C. C. Bass and J. A. Watkins describe "A Quick Macroscopic Typhoid Agglutination Test." In carrying out this quick test a drop of 1 in 5 dilution of blood is placed on an ordinary plain microscopic slide along with a drop of a specially dense (about 10,000 millions per c.c.) emulsion of *B. typhosus*. The two drops are mixed together on the surface of the slide, and made to move to and fro by gently rocking the latter for two minutes. A positive result is indicated if the emulsion is broken up into small white masses or clumps visible with the naked eye.

The technique about to be described is simply an elaboration of Bass and Watkins's method with the object of rendering it not merely a qualitative test for agglutinins in the blood, but an accurate quantitative estimation of the agglutinin titre of the blood. This object is attained by means of an apparatus which I have devised and called a "clinical agglutinometer."

The clinical agglutinometer consists of the following parts:—

1. *A diluting slab*.—A painter's palette made of glazed white porcelain having three rows of seven small cups, and a trough in which the saline solution is contained. (See Fig. 1.)

2. *Diluting pipette*.—An ordinary dropping pipette with teat.

3. "Standard"

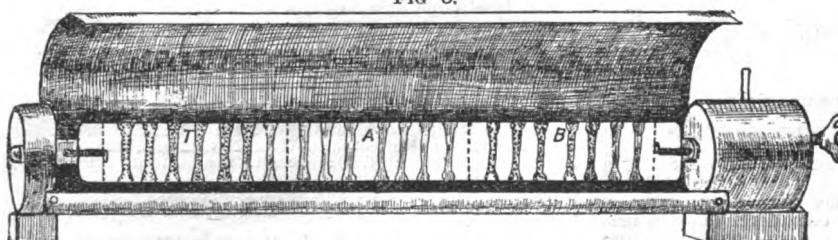

*platinum loop in handle*.—The loop is 3 mm. diam. and bent at a right angle with the stem of the wire.

4. *The agglutinometer slide*.—

A piece of ordinary clear glass 25 cm. long, 30 mm. broad, with smooth edges. It is divided by two lines crosswise into three equal parts. (See Figs. 4, 5, and 6.)

5. *Set of emulsion bottles in stand*.—The bacterial emulsions I have used in the agglutinometer are: *Bacillus typhosus* Eberth, *B. paratyphosus A* Brion-Kayser, *B. paratyphosus B* Schottmüller, *B. dysenteriae Shiga*, *B. dysenteriae Flexner*, *B. dysenteriae His*, *B. enteritidis Gaertner*, *B. faecalis alkaligines*, *B. coli communis*, *Vibrio cholerae* Koch, *Micrococcus melitensis* Bruce, *M. paramelelitensis*. The emulsions are made from 24-hour surface agar cultures. The growth is scraped off the surface of the medium in platinum loopfuls and emulsified in 0.1 per cent. formalin in normal saline. The emulsions used for this method should be dense ones—about 10,000 millions per c.c.

FIG. 3.

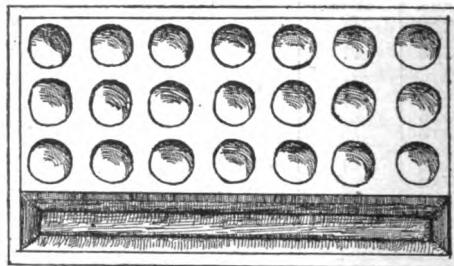

The density of all the emulsions should be uniform as far as the eye can judge. Each bacterial emulsion is contained in a small clear glass bottle with wide mouth, having a stopper bearing a "standard" platinum loop bent at a right angle with the stem of the wire. These platinum loops are in all respects the same as the platinum loop in handle. The most generally useful emulsions for diagnostic purposes are *Bacillus typhosus*, *B. paratyphosus A*, *B. paratyphosus B*, and *Micrococcus melitensis*. (See Fig. 2.)

6. *The mechanical mixer*.—This consists of a mechanical contrivance, by means of which the agglutinometer slide is

made to revolve on its long axis slowly (about ten revolutions per minute) in an atmosphere saturated with aqueous vapour. The moist chamber is a cylinder of celluloid placed horizontally, the upper half being jointed to form a lid, the lower half lined with filter paper soaked with water. The revolving movement is obtained by means of a simple clockwork attached at one end of the cylinder. It can be stopped at will by means of a lever (after the manner of a Dudgeon's sphygmograph). (See Fig. 3.)

7. *A pocket centrifuge*.—A small apparatus, not larger than a matchbox and weighing less than two ounces, for centrifuging the blood in Wright's capsules.

FIG. 1.

8. *Pocket lens*. Spirit lamp. Bottle of normal saline. Swabs of cotton-wool. Wright's capsules. Agglutinating sera.

*Description of Technique in the Use of the Clinical Agglutinometer.*

1. *The diluting process*.—(a) The blood for examination is taken from the lobe of the ear in the usual manner into a Wright's capsule, and centrifuged.

(b) By means of a dropping pipette (which during the whole process should be held vertically to ensure equality in size of the drops) place four drops of saline into cup No. 1 of the diluting slab and two drops into each of the other cups in the row.

(c) To cup No. 1 add one drop of the serum to be tested and mix

size of the drops) place four drops of saline into cup No. 1 of the diluting slab and two drops into each of the other cups in the row.

(c) To cup No. 1 add one drop of the serum to be tested and mix

thoroughly by drawing into and expressing from the pipette three times. This forms a 1 in 5 dilution of the patient's serum.

(d) Transfer two drops from the cup No. 1 to cup No. 2, and again mix thoroughly. This forms a 1 in 10 dilution.

(e) Again transfer two drops from cup No. 2 to cup No. 3, and mix thoroughly. This yields a 1 in 20 dilution, and so on to cup No. 7 (1 in 320 dilution).

2. *The mixing process*.—The process of mixing the blood serum and bacterial emulsions is carried out on the surface of the agglutinometer slide. The 25 cm. slide, divided by two lines into three segments, is long enough to take a triplicate series of the seven dilutions, so that the titre for T., A, and B emulsions can be found simultaneously.

Beginning with the highest dilution (1 in 320) loopfuls of the various dilutions of blood serum are deposited in triplicate on the slide which is lying flat on the bench. Opposite each loopful of serum is placed a loopful of bacterial emulsion, as shown in Fig. 4.

Equality in size of loopfuls can only be obtained by holding the handle of the platinum loop vertically throughout the entire process. Beginning with the highest dilution and passing towards the lowest, the loopfuls of serum and emulsion are mixed

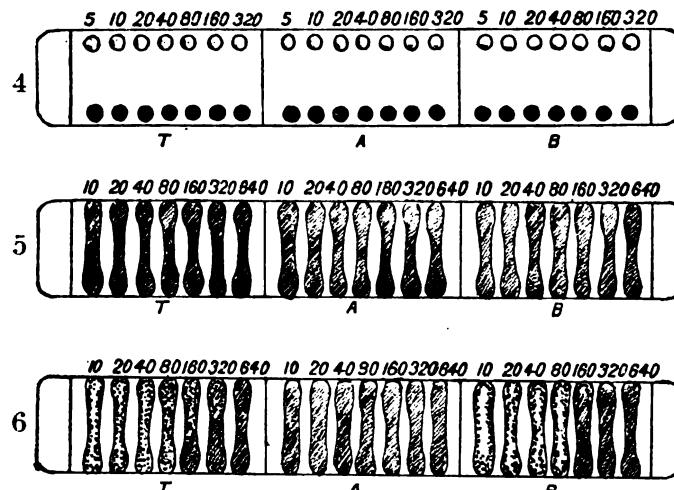

across the slide with the edge of the platinum loop. When this is complete there are on the surface, mixtures of bacterial emulsions of T., and A and B with blood serum in the following titres: 1/10, 1/20, 1/40, 1/80, 1/160, 1/320, 1/640. (Fig. 5.)

The slide so loaded is placed carefully in the moist chamber of the mechanical mixer where it is received and held fast by a clip at each end. The clockwork is started by means of the lever, and the slide allowed to revolve slowly for five minutes, during which time the mixtures run to and fro across the slide. The bulk of fluid is not enough to allow

the mixtures to run off the slide at the edges, nor for the various dilutions to run into one another.

At the end of five minutes the agglutinometer slide is removed and examined by the naked eye (aided, if necessary, by a pocket lens) in a good light against a black background. Agglutination converts the mixtures from homogeneous milky emulsions into a condition in which the agglutinated masses of bacilli float about like minute white flakes in a clear fluid. In a strongly agglutinating blood this takes place in the lower dilutions almost instantaneously after the agglutinometer slide begins to revolve. The change is very striking and can be easily seen with the naked eye. In the higher dilutions the change may take three or four minutes and be observable only with the aid of a pocket lens. If no change is visible with the pocket lens in the 1 in 10 dilution at the end of five minutes' time limit no agglutination of any diagnostic significance is present in the blood.

The diagram, Fig. 6, represents the appearance of the agglutinometer slide in the case of a patient whose blood agglutinates T. up to 1 in 320 and B up to 1 in 160, the A emulsion being negative.

(Note.—It is absolutely essential that the examination of the slide be carried out in a good light against a black background some distance away (say 3 or 4 feet), otherwise it is difficult or impossible to read the results.)

In examining the bloods of patients suffering from typhoid and paratyphoid infection it will frequently happen that all the dilutions up to 1 in 640 show agglutination. In such a case a further series of higher dilutions in the same geometrical progression is made, thus :—

(a) Into each of the cups in the second row on the diluting slab drop two drops of normal saline.

(b) Transfer two drops from the 1 in 320 dilution to cup No. 1 of the second row and mix thoroughly—this makes 1 in 640 dilution.

(c) Transfer two drops of 1 in 640 dilution into cup No. 2 of the second row and mix thoroughly, and so on to as high a dilution as it is considered necessary to reach the agglutinin titre of the blood. Now clean the agglutinometer slide with a cotton-wool swab wet with 5 per cent. carbolic, dry it, and flame it. Distribute the higher series of dilutions in platinum loopfuls on the slide in precisely the same way as for the lower series of dilutions, place opposite each dilution a loopful of emulsion, mix the two together across the slide, and place the slide in the mechanical mixer as before. The agglutinin titre of the blood is the highest dilution in which definite flakes of agglutinated bacilli can be seen with the aid of a pocket lens. It is, of course, essential that the dilution beyond this (the ultimate dilution) be absolutely negative. This indicates the penultimate dilution as the limit of the agglutinin titre of the blood and acts as a control for each test.

#### Theory of Action of the Agglutinometer.

For the purpose of explaining the action of the agglutinometer the phenomenon of agglutination may be considered to consist of two processes :—

1. The union of agglutinin with the agglutinable substance (whether this is in the nature of a true chemical union or is merely "adsorption" is here immaterial).

2. The aggregation of the bacilli into clumps. Both these processes are greatly accelerated by the movement to and fro to which the mixtures of serum and emulsions are subjected in the mechanical mixer. Different portions of agglutinin

and agglutinable substances are constantly being brought into contact with one another and their union facilitated. The same constant movement of a staining solution over a section of tissue or a blood film hastens the staining process and renders it more complete. For the same reason photographers use a mechanical rocker which causes the developing solution to move constantly to and fro over the photographic plate. The physical change—the aggregation of the bacilli into clumps—is also greatly accelerated by rolling the bacilli on one another. In the lower dilutions in which agglutinin is concentrated, agglutination appears instantaneously throughout the emulsions, but in the higher dilutions, in which agglutinin has been reduced to a mere trace, the clumps will be seen to form slowly along two lines which correspond to the junction of the quickly moving central stream and slowly moving peripheral stream on either side—that is to say, the position in which the rolling action on the bacilli is most marked. They tend to pass outwards into the peripheral stream and finally settle along the edge of the fluid.

#### The Uses and Advantages of the Clinical Agglutinometer.

**Simplicity.**—The technique is simple and easy. Little is left to the manipulative dexterity of the operator, and thus satisfactory results should be obtained by men with little experience of the method.

**Speed.**—The method is extremely rapid. After a little practice, specimens of blood can be examined and the results recorded at the rate of 10 per hour—an all-important consideration in war-time.

**Accuracy.**—The titre found by the agglutinometer in 5 minutes is the same on an average to within one dilution, as that obtained by the elaborate method in tubes in 2-24 hours. The end-point is as sharp as that in tubes and easily read after a little practice. The method is therefore capable of detecting with all sufficient accuracy those fluctuations in titre which take place during the course of enterica. The special sphere of usefulness of the clinical agglutinometer is in the making repeated examinations in those cases of clinical enterica after triple inoculation in which attempts at isolation of the bacillus from the blood, urine, and faeces have failed. Evidence is accumulating that in these cases this special method of examination gives valuable help in diagnosis at a small cost in time, trouble, and material.

The diagrams illustrating this article were kindly drawn for me by Captain Philip H. Bahr, R.A.M.C. This agglutinometer may be obtained through Dr. Thos. G. Nicholson, resident medical officer at the London Fever Hospital, Liverpool-road, Islington, London, N.

#### A SHORT NOTE ON

### THE EFFECT OF PYREXIA ON INOCULATION AGGLUTININS.

BY G. SELBY WILSON, M.B., B.S. LOND., M.R.C.S.,  
L.R.C.P. LOND.,  
TEMPORARY LIEUTENANT, R.A.M.C.

(From the Bacteriological Laboratory, Charing Cross Hospital.)

In consideration of the large number of results which have been published by Dreyer, Inman, and Ainley Walker, working by the macroscopic method on the one hand, and Tidy, working by the microscopic method on the other hand, in regard to the effect of pyrexia on the agglutinin content of the blood of those persons who have been previously inoculated with typhoid vaccine, and in view of the discordancy which has occurred in the conclusions which have been drawn from these two methods, it was suggested that it would be interesting to examine the serum of each individual patient by both the macroscopic and microscopic procedures. For this purpose a series of 97 soldiers and others, who had been inoculated within the preceding 20 months against typhoid fever, was taken, and the agglutinin titre of the

serum of each case was estimated in the manner already stated.

The technique of the experiments was as follows:—

The macroscopic method was similar to that employed by Dreyer, with the exception that the killed typhoid emulsion was not standardised, so that the results as here given cannot be recorded in terms of his agglutination units. Tubes were put up in the following dilutions of serum: 1 in 25, 50, 125, 250, 500, 750, 1000, 2500, 5000, and 7500. The end point was taken as occurring in that dilution in which agglutination was just visible with the aid of a small magnifying glass. Thus, e.g., if agglutination could just be seen in a dilution of 1 in 500, this was taken as the end point, but if agglutination was quite distinct in a dilution of 1 in 500, and was absent in a dilution of 1 in 750, the end point was taken as the mean of these two—namely, 1 in 625.

For the microscopic method an emulsion of bacilli was prepared from a 24 hours' subculture on agar, the same strain of bacillus being used throughout the whole course of experiments, both macroscopic and microscopic. Dilutions of serum were put up as 1 in 25, 50, 125, 250, and 500. The end point was taken as that dilution in which marked agglutination was present after half an hour's exposure at room temperature; this did not exclude the presence of a few motile bacilli. In case of doubt as to the exactness of the reading, an intermediate dilution was put up. Dilution was continued till no agglutination was seen, and this was found to be not greatly in excess of that in which marked agglutination was present.

The cases have been divided into three classes:—

*Class I.* contains those patients who subsequent to inoculation had run no temperature at all.

*Class II.* contains those patients who since their inoculation had run a temperature of 102° F. or more for at least four days, generally not longer than a week.

*Class III.* contains those patients who since their inoculation had run a temperature of between 100° and 102° for periods of over a week, in many cases lasting for several weeks.

A glance at the tabulated figures will show:—

1. That the average agglutinin titre of sera obtained from patients who have suffered from a febrile attack since inoculation is lower than that of those who have had no such attack.

2. That as regards the effect of pyrexia on the agglutinin titre there appears to be no appreciable difference between a short high and a long low temperature.

3. That in this respect the results as obtained by the macroscopic and microscopic methods, taken on the average, are very similar; thus the average dilutions in which agglutination occurred in *Class II.* and *III.* are practically half of those in which agglutination occurred in *Class I.*, as estimated by both methods.

4. That the relations in the individual cases between the two methods are extremely variable, the macroscopic method showing very marked agglutination in some cases in which the microscopic failed to demonstrate any at all. It will be noticed that the difference between the average results in the various classes cannot be due to a variability in time from the date of inoculation, for they all approximate to the same period of months.

5. That it is an obvious advantage when making repeated quantitative estimations to use a method which gives agglutination over a great range of dilution, since small differences are so much more easily recognised. Especially is this the case in dealing with the question of the diagnosis of typhoid in inoculated patients, when frequent examinations at short intervals are required.

Before drawing any conclusions from these figures it would be well to notice Tidy's statement in *THE LANCET* of Jan. 29th, 1916, to the effect that a temperature of 102° F. lasting for four days is apparently sufficient to lower the agglutinin content of the blood to such an extent that a negative reaction will be obtained; if, on the other hand, complete agglutination in a 1 in 50 dilution of serum by the microscopic method is present on the fifth day, the patient is probably suffering from an attack of typhoid fever. Now, were this the case, no fewer than 25.9 per cent. of the patients in *Class II.*, which consists of those who had run a temperature of 102° F. or over for four days or more must have been suffering from typhoid fever, whereas clinically they presented no symptoms or signs of such a condition, the great majority of the temperatures in the whole series of cases being due to septic wounds.

The results obtained were:—

*Class I.: 48 Cases.*

*Class II.: 27 Cases.*

<i>Conclusions.</i>											
1. That although comparison of the arithmetic mean of the various series suggests that the effect of febrile attacks is to lower the agglutinin titre, yet, in view of the comparatively small number of cases examined and the wide range of variation in the results obtained, it would be unsafe to draw any definite conclusions. In certain of the investigations already published a comparison has been made between such series of results on the basis of the value of the middle term of each series; it will be seen that such a method of comparison employed in the figures here recorded gives an entirely different result from that obtained by utilising the arithmetic mean, and this may be taken as further evidence that such series are not strictly comparable. It would seem, however, that the mean value offers the better standard of comparison, since a single high agglutinin titre affects to too great an extent the whole results if the middle term be employed. It may be concluded that such a series as the above offers only a suggestion that febrile conditions decrease the agglutinin titre, and more extended investigations must be awaited before a final judgment upon the subject can be passed.											
2. That persistence of agglutinins in the serum of a patient who has had a temperature of 102° F. for four days, whether estimated by the macroscopic or the microscopic method, is insufficient to justify a diagnosis of typhoid fever.											
3. That the macroscopic method suggested by Dreyer offers obvious advantages when repeated quantitative estimations of the agglutinin titre have to be made.											
I should like to express my thanks to Dr. W. W. C. Topley, at whose suggestion this work was undertaken, and by whose kindness I have been able to carry it out.											

### Conclusions.

- That although comparison of the arithmetic mean of the various series suggests that the effect of febrile attacks is to lower the agglutinin titre, yet, in view of the comparatively small number of cases examined and the wide range of variation in the results obtained, it would be unsafe to draw any definite conclusions. In certain of the investigations already published a comparison has been made between such series of results on the basis of the value of the middle term of each series; it will be seen that such a method of comparison employed in the figures here recorded gives an entirely different result from that obtained by utilising the arithmetic mean, and this may be taken as further evidence that such series are not strictly comparable. It would seem, however, that the mean value offers the better standard of comparison, since a single high agglutinin titre affects to too great an extent the whole results if the middle term be employed. It may be concluded that such a series as the above offers only a suggestion that febrile conditions decrease the agglutinin titre, and more extended investigations must be awaited before a final judgment upon the subject can be passed.
- That persistence of agglutinins in the serum of a patient who has had a temperature of 102° F. for four days, whether estimated by the macroscopic or the microscopic method, is insufficient to justify a diagnosis of typhoid fever.
- That the macroscopic method suggested by Dreyer offers obvious advantages when repeated quantitative estimations of the agglutinin titre have to be made.

#### CLINICAL SECTION.

*Toxic Jaundice due to T.N.T. Poisoning.—Primary Carcinoma of Liver.*

A MEETING of this section was held on Feb. 9th, Surgeon-General H. D. ROLLESTON, R.N., the President, being in the chair.

Dr. R. MURRAY LESLIE showed a case of Toxic Jaundice due to T.N.T. Poisoning. The patient, a woman aged 28, after being engaged in handling T.N.T. for about 14 days, noticed that her hair, which was originally fair, had become of a "ginger" colour, but her general health did not suffer in any way, and she continued at her work for a fortnight after the change in the colour of the hair had been noticed. She remained quite well for one month after leaving her employment, although the ginger colour of the hair persisted. At the end of this time, however, she noticed that the skin of the face became yellow, and in about one week the skin of the whole body was similarly affected. This yellow colour gradually deepened, and she stated that the whites of the eyes became tinged later. A fortnight after the appearance of the jaundice she noticed a "cankery taste," lasting for about an hour after taking food. Afterwards she had occasional vomiting, which seemed to relieve the disagreeable taste, and during the same time suffered from diarrhoea—three or four loose and offensive motions daily, very pale in colour. During the same period the urine was very dark—something like the colour of "strong tea." A week before admission a rash broke out over the body. She thought she had lost weight. On admission the hair was of a peculiar ginger-yellow hue, while the skin of the face and body was markedly jaundiced, with similar icteric tinging of the conjunctivæ. There was also a raised erythematous rash—a sort of superficial dermatitis—affecting the skin of the arms, chest, back, abdomen, buttocks, thighs and legs, producing, in association with the jaundice, a curious bronzed appearance. This erythema was accompanied by some irritation. The bowels tended to be relaxed and the motions were of a pale pipe-clay colour, but there was no actual diarrhoea, which had been present during the previous fortnight. The urine was of a dark brownish-green colour, and contained bile salts and bile pigments, and also a slight amount of albumin. Acetone was also present during the first ten days, but was not found in subsequent examinations. The specific gravity was 1020 and the reaction acid. Blood, tube casts, leucin, and tryosin crystals were not found. The liver dullness seemed slightly reduced and did not extend quite so far down as the costal margin, but there was no definite pain or tenderness on palpation. The temperature on admission was 99° F. and the pulse 100. Her weight was 8 st. 6½ lb. For the first three days the patient remained *in statu quo* and was not obviously ill or distressed. On the fourth day after admission, however, she got much worse, and her condition gave rise to considerable anxiety. The temperature rose to 102°, and there was remittent pyrexia for the next five days, the evening temperature on the sixth day after admission being 103°. There were no drowsiness, convulsions, or other alarming nervous symptoms, and no actual distress. She was indeed bright and cheerful throughout. Acetone at this time was present in the urine. After a week's pyrexia the temperature fell to normal, and with the exception of occasional rises of temperature in the evening to 99°, and on one occasion to 100°, there was no pyrexia during the rest of the patient's stay in hospital. The erythema disappeared within the first 14 days. The jaundice persisted unchanged for the first three weeks and then gradually diminished. The albumin disappeared from the urine. During the first three weeks the patient lost 6 lb. in weight, which she regained in the next fortnight. There was complete amenorrhœa for three months. After her discharge from the hospital she remained well except for an attack of epistaxis and diarrhoea, but slight jaundice persisted. The presence of acidosis, in association with pyrexia, during the first ten days suggested the administration of alkalies. Half-drachm doses of bicarbonate of soda were given every two hours during the day for eight weeks, after which the

same doses were given every four hours. When the pyrexia subsided the patient was put upon ordinary diet, with an excess of carbohydrates. The alkaline treatment was suspended during the past month, but since the recent attack of diarrhoea and hepatic pain it had been resumed in drachm doses three times daily.

Dr. F. PARKES WEBER read a short paper on two cases of Primary Carcinoma of the Liver. The first was an example of "cirrhosis carcinomatosa," the neoplasm originating from the hepatic cells in a cirrhotic organ. In the other the growth was of the "massive" type, probably originating from the epithelial cells of small intrahepatic bile-ducts. Before death thrombosis of the whole of the inferior vena cava occurred.

### MEDICAL SOCIETY OF LONDON.

#### *Naval Medicine in the Great War.*

A MEETING of this society was held on Feb. 12th, Lieutenant-Colonel D'ARCY POWER, R.A.M.C. (T.), the President, being in the chair.

Surgeon-General H. D. ROLLESTON gave an address entitled "Naval Medicine in the Great War," which is published in full in our present issue.

Surgeon-General Sir ARTHUR MAY, D.G., R.N., spoke of the high standard of health in the Navy and paid a glowing tribute to the civilian medical men of all grades who had joined the Royal Naval Medical Service during the war. He especially emphasised the self-denial of the surgeon-probationers and the excellence of their services.

Dr. F. W. MOTT said that as regards mental trouble among soldiers he had found that usually there had been some antecedent condition of nervous instability. Shell shock also occurred in those of a temperamentally nervous disposition. He was interested in what had been said about nitrous oxide fumes, and had recently received a brain, preparations of which showed that there had been a profound effect upon the blood, the haemoglobin being probably converted into methaemoglobin. The speaker regarded the process of adaptation as the main factor involved. The state of adaptation was the barrier by which perceptions liable to arouse the primary instincts were prevented from arising in consciousness to their true significance. Once adaptation had failed, or a vivid perception had pierced through and succeeded in arousing the primary instincts, the path was laid open for succeeding ones of less strength, and the consequence was that the individual had to maintain his normal level against an ever increasing load of mental stress. By various psychological processes the eventual production of any one of the clinical types could be explained, each individual case, of course, depending on its special attributes. The development of the various conditions demanded time, and this was afforded by the special conditions of modern naval warfare—the long periods of purely routine work with a constant anticipation of real action. The remarkable feature was that the average man should be capable of adaptation to such a degree as to enable him to withstand such conditions over so long a period as he did. It would not be possible were it not that in the process of civilisation a number of secondary instincts had been produced which acted in opposition to, and helped the individual to overcome the promptings of, the primary instincts; these were the herd instincts, such as the instincts of duty, morality, &c., and the religious instinct. In a ship the close relationship between individuals necessitated by the confinement of space tended to the production of a specialised herd instinct, usually termed the morale. Where the morale was strong the individual was saved from a great deal of the mental stress to which he might be subject, and cheerfulness and confidence with mental stability resulted. It could safely be stated that the morale of our ships at sea had lost nothing of its high degree since the war began, long as the time had been and however unmentioned the task. The very small relative increase in the numbers of the cases was due to the decided difference between conditions of peace and of war and to the unpreventable inclusion of a few less constitutionally sound individuals in the greatly enlarged personnel of the service.

Dr. THOMAS BEATON, Temporary Surgeon, R.N., referred to the Neuroses and Psychoses of the Sailor at War. The number of cases of this description admitted to the Royal Naval

Hospital, Chatham, had steadily increased until, in the last quarter of 1916, the admissions were six times the average quarterly admissions in peace-time. The relative incidence to the total number of medical cases admitted, however, had only increased by 2 per cent. each year of the war. 60 per cent. of the cases showed conduct which could be termed insane, the remaining 40 per cent. consisting of the pure neuroses and the psycho-neuroses. The clinical types of insanity did not differ to any great extent from those observed in civil practice. General paralysis, which occurred to the extent of 5 per cent., almost invariably showed a marked dementia rather than any definite delusional state. Cases of non-systematised delusional insanity, which were the most common, had a tendency towards rapid recovery under the influence of hospital life and the removal of circumstance of stress. There was generally a condition of congenital defect underlying the delusional content. The types of neuroses differed to a certain degree from those occurring in civil life. True neurasthenia was very rare, whilst hysterical states, mutism, functional paralyses, &c., were extremely infrequent and only seen in cases of a previously hysterical nature. The majority of the cases were of a type bordering on the neurasthenic on the one hand, and on the obsessional case on the other, showing distinct mental aberration but little derangement of the general bodily condition. This condition, termed "psychasthenia" by the speaker, occurred in association with congenital mental deficiency in the youth and the young adult, with senile and atheromatous change in the middle-aged and old adult, and between those ages almost invariably followed on a period of especially arduous stress. The fact that mental disturbance was the main feature of the whole series of cases indicated that the cause would ultimately be expressed in psychological factors. The actual severity of the circumstances under which the conditions developed did not necessarily indicate the extent of the mental disturbance to be produced, but obviously bore an inverse ratio to the resisting power of the individual.

Dr. A. F. HURST said that overactivity of the suprarenal glands could account for a large proportion of the ordinary manifestations of fear and anger. These were in the nature of preparation for action, and if too prolonged exhaustion of the suprarenal glands (and possibly of the thyroid) occurred. This explained the low blood pressure met with after serious illnesses in soldiers, a pressure which gradually improved as the cases got better. There was an overaction of the thyroid and suprarenal together in cases of apparent hyperthyroidism, and the blood pressure was higher than one would expect with simple overactivity of the thyroid. With rest, bromide, &c., the pressure fell. The cases of tabes and general paralysis brought on by shock and strain improved so much by treatment that he had been almost tempted to send them back to service. This he ascribed to the fact that they were secured in a very early stage. For war-dreams he had found hypnotism very successful, even one treatment sometimes causing their cessation. It was important that it should be employed at night so that the patient could afterwards be left to sleep until morning. He regarded the doubtful intestinal cases met with in the Mediterranean as examples of true dysentery, for it had been his experience that in all cases in which mucus and blood were present in the stools, the amœbae were found. Large injections intravenously of serum had proved remarkably successful. Of the beri-beri cases seen, the majority had had jaundice and the remainder some gastro-intestinal symptoms. He favoured the view of Hamilton White that the jaundice was due to duodenal infection, which was followed by a toxic neuritis as in the case of diphtheria.

#### JOURNALS.

*Indian Journal of Medical Research*, Vol. IV., No. 2.—The first article in this number is a note on the tests for certain narcotic and anaesthetic drugs, by Dr. E. H. Hankin, chemical examiner to the Government of the United Provinces of Agra and Oudh. A recent Army Council Order restricts the sale of some of these drugs to soldiers, and as no tests were known, or at least generally known, for some of them Dr. Hankin is right in thinking that his "Note" may prove of service.—Mr. C. Strickland, travelling medical entomologist, Federated Malay States, contributes three papers, the first of which gives interesting observations on the epidemiology of malaria fever in the Malay Peninsula. The author advances what he terms an "epidemiological paradox"

—namely, that while on the alluvial coast-belt malaria is incident on proximity to undrained jungle, in the hills and mountains malaria would not appear to be so incident; conversely, health results on the flat coast if the jungle be felled and drained; in the hills, if land be cleared and drained, malaria becomes prevalent. This means, in Mr. Strickland's opinion, that *A. umbrosus*, which causes malaria on the flat coast-belt land, will not breed in the hills, and that *A. maculatus* and others which cause fever in the hills will not breed on the coast alluvium. Exactly why this is so is now being investigated, and will be reported upon in due course. This paper was laid before the Federal Council of the Malay States by command of His Excellency the High Commissioner, and is reprinted in the *Journal* by permission. In his second paper Mr. Strickland describes a new species of *Protanopheline* from Malaya—*Myzorhynchos hunteri*; and in his third article he gives a description of a new species of umbrosus-like anopheline from Malaya—*Myzorhynchos novumbrosus*.—Major Clayton-Lane, I.M.S., contributes an interesting report on an investigation into ankylostoma infection in 11,000 inhabitants of the Darjeeling district. This inquiry was made with a view to determine the amount of the infection present among these people and with the object of freeing them from the disease, as well as for the purpose of observing what effects this had upon the health and working efficiency of such persons. The investigation was conducted upon the coolies engaged in several tea-gardens. The results showed that 66·02 per cent. of those examined were infected by *Necator americanus*, the only kind of ankylostoma present in this part of India. Incidentally infestation by other parasitic intestinal worms was revealed, 67·68 per cent. having *Asoaris lumbricoides*. A further report upon his inquiry is promised by Major Clayton Lane at a future date.—The Gland-Index in Tuberculosis is the title of a paper furnished by Dr. A. C. Lankester, giving some results observed by him in the course of his special tuberculosis inquiry in India. It has been suggested that it may well be that the proportion of enlarged cervical glands, tuberculous in origin, may be sufficiently large to determine a true correlation between the percentage of children showing enlargement of these glands and the number of cases of phthisis in the community to which they belong. If such a correlation can be established then the examination of children in various schools would seem to afford a very ready means of measuring the degree of prevalence of tuberculosis in their homes, and thus a comparison of cities and districts with one another as regards prevalence of consumption might be instituted, as also of various social and religious communities throughout the country. In his inquiry Dr. Lankester examined over 900 children and found 29·49 per cent. with enlarged cervical glands, but he was forced to the conclusion that the gland-index method needs to be further safeguarded before it can be regarded as suitable for general adoption as a means of measuring tuberculosis prevalence; the method, however, is well worthy of continued investigation, and he hopes to have the opportunity of testing it again in several directions.—Major W. F. Harvey, I.M.S., contributes two papers, the first being entitled "Some Facts Relating to Birth and Marriage Rates among Brahmins" and the second "Birth Rates, Marriage Rates, Fertility and Proportion of Sexes at Birth among some Fighting Communities." Both of these papers are supplemented by statistical tables.—A note on the effect of inoculating rabbits with cholera vaccine prepared in various ways is supplied by Captain C. J. Fox, I.M.S., who undertook this work in order to ascertain the relative value of different kinds of cholera vaccine which would combine a high immunising power with a minimum of local and general reaction. This, it appears, was called for, as the cholera vaccine prepared by Professor Haffkine produced a severe general and local reaction. The results showed that from the point of view of agglutinative power the most effective immunising vaccine appeared to be a heated one without phenol; and from the point of view of efficiency combined with minimum reaction the choice appeared to be in favour of a carbolised vaccine.—Captain A. L. Sheppard, I.M.S., gives an account of his experiences of scurvy in Zhob, Baluchistan, discussing also the clinical characters and etiology of the disease. He found that the seasonal prevalence corresponded exactly in this district with food scarcity, especially of vegetables, fresh meat, and milk. He is, however, led to ask, Is scurvy entirely due to deficiencies of diet, or is this only a predisposing cause?

# THE LANCET.

LONDON: SATURDAY, FEBRUARY 17, 1917.

## The Medical Department of the Navy in the War.

THERE is always a pleasure in examining a great and complex mechanism, in seeing how it moves, and how the various parts have been adapted, each for its own purpose. Just such an insight into the working of that elaborate machine, the Medical Department of the Royal Navy, was given us by Surgeon-General H. D. ROLLESTON in his address to the Medical Society of London on Monday last, which is printed in the present issue of THE LANCET. Before the war the Navy included more than a hundred thousand persons in all ranks, but with the outbreak of hostilities its personnel was enormously increased—we believe that no official figures have been published but it is well known that there are now at least half a million men holding permanent or temporary positions within the Navy, a number that must be quite unprecedented in the navies of the world. With the expansion of the numbers of the Navy it was clear that the Medical Department must increase also, and at even a higher rate, for with active service the need for medical and surgical assistance undergoes enormous increase. Up to the present no great sea fight, commensurate with the size of the opposed fleets, has occurred, but there have been sick and wounded, amply sufficient in number to test the working of the elaborate arrangements which have been made for their care and treatment, and numerous enough also to show how wise the naval authorities have been to expand the Medical Service vastly in preparation for worse things.

The system which the necessities of war have evolved has been dependent on what may seem, until circumstances change the point of view, an excess of preparation, and herein lies the interest of the more striking points in Surgeon-General ROLLESTON's address. First, as to the staff. A large number of temporary surgeons were enrolled, and in addition ten consultants were appointed, most of them to serve in the main base hospitals, with pathologists to carry on their duties in the clinical laboratories. In addition to these a new rank of medical service was devised. In peace time the smaller ships, such as destroyers, are not provided with any real medical attendance. Some of the officers and men have a certain amount of knowledge of the administration of first-aid in emergencies, and such knowledge has been found in practice to be sufficient. Indeed, many of the destroyers for a great part of the present war have had no surgeon on board. To remedy this deficiency the Medical Department of the Navy has appointed medical students who have passed in anatomy

and physiology but have not passed their final examinations, and has called them surgeon-probationers. They have been given some training at Haslar and they have proved their usefulness on many occasions. The question of the transport of the sick and wounded has also received particular attention, as would be expected when the conditions of naval casualties are considered. Four naval ambulance trains have been provided, and carry the patients from the ambulance ships and the naval hospitals near the naval bases to the large naval hospitals at Plymouth, Haslar, and Chatham. An excellent plan has been devised by Sir JAMES PORTER and Staff-Surgeon A. V. ELDER by which the Service cot, in which the patient is brought from the ship, is fixed firmly in the train, so that there is no necessity for transferring him from a stretcher to a cot in the ambulance train; this must save an enormous amount of discomfort and pain. The present great speed of the units of a battle fleet makes it practically impossible for a hospital ship to keep in touch with the fighting ships during a battle, and, moreover, in the midst of a battle a battle-ship or cruiser cannot heave to for the purpose of transferring the wounded to the hospital ship, for that would be to expose the ship to the risk of a torpedo. The hospital ship can only come into use after the action has ceased, and this is the fact that has been kept steadily in view by those responsible for the organisation. It is difficult to give any exact statistics as to the proportion of killed and wounded in modern naval actions, for when several ships are sunk it cannot be said how many of the crews have been killed by the enemy's fire and how many drowned, but on the whole the proportion of killed has been high. The amount of shock in the wounded seems to have been great, and immediate operation is therefore to be avoided as far as possible, while for the relief of shock the value of hypodermic injections of morphia appears to have been proved. The Royal Naval Division have seen active service in Belgium, Gallipoli, and France, and therefore have been exposed to the same risk of disease and injury as the armies with which they have worked.

To turn from wounds in battle to the incidence of disease, the amount of sickness in the Fleet has been wonderfully small, less even than in times of peace. With regard to infectious diseases, the most striking and noteworthy point was the severity of measles amongst the Shetlanders both in the Fleet itself and amongst the reservists stationed on shore. In the Orkney Islands Dr. R. P. HEDDLE, of Kirkwall, states that measles may be entirely absent for 15 or 20 years, but when the disease does appear, though the children have mild attacks, the adults take it very severely and seem to be especially liable to have pneumonia as a complication. The good health of the men is doubtless to be attributed mainly to the isolation of the Fleets, so that the risks of venereal infection and alcoholic excess were reduced to a minimum, but some of the improvement must certainly be attributed to the lectures delivered by the medical officers to the crews, dealing with the dangers alluded to. The monotony of waiting for

actions which never appear to come was anticipated by the authorities. It has told, we believe, far more hardly upon the officers than upon the men, among whom it has been in great measure obviated by means of regattas, boxing competitions, and other entertainments. Cinema shows have also been very useful, and a scheme has been devised for circulating films between the various ships. Great credit must be given to the arrangements which have been made. It was, however, the Naval Division in Gallipoli which suffered most from sickness; dysentery, diarrhoea, typhoid, paratyphoid, and jaundice all caused a large amount of invaliding, as has been made clear in many communications to our columns. Surgeon-General ROLLESTON discussed in his paper many of the points in connexion with these diseases, and the conclusions which he drew, as well as his brief account of the diseases incident to the Naval Air Service, will be received with pleasure. Altogether the paper was wonderfully instructive and interesting, and showed the success of the organisation of the Naval Medical Service.

### Tuberculosis and the War.

A YEAR ago a symposium in the *British Journal of Tuberculosis* afforded an occasion to consider the treatment of tuberculosis and the effect of the war upon the methods of carrying it out. Active measures had already necessarily been much curtailed, but we pointed out the necessity of unremitting attention to the public health aspect, especially the conveying of infection from person to person in the close contacts of poorer city life must be avoided. Equally important we felt to be the treatment of the earlier stages of tuberculosis which are preëminently curable in the growing child. At that time the effect of war conditions on the tuberculous soldier himself was largely a matter of conjecture, but it seemed, at all events, probable that the healthy outdoor life with abundant food and exercise in the fresh air was meaning for the sometime industrial worker an improvement in his chance of keeping the upper hand in a personal struggle with the tubercle bacillus. A year has passed away and the effect is still conjectural, but there are certain indications as to the directions in which progress may be looked for, and another symposium in the *British Journal of Tuberculosis* affords at the moment valuable information.

Taking first the tuberculous soldier, it is evident, we think, that camp and trench life has not been productive of more breakdowns than would have occurred in civilian employment. Dr. T. D. ACLAND, in a contribution to the symposium, quotes Mr. TENNANT'S statement in the House of Commons that up to March 1st of last year 2770 tuberculous soldiers had been discharged from the Army. It is a matter of common knowledge how reckless was the admission to the Army in the early days of men with clinical signs of tuberculosis, and the number of such will, of course, only amount to a tithe of those with latent or hardly recognisable disease.

It is amazing that in a citizen army running to millions the incidence of breakdown from tuberculosis all told should have been only in the lower thousands. A rough calculation of breakdown from the same cause among the men of military age in industrial occupations would give a vastly higher total. This stands out as an encouraging factor in a vastly perplexing situation, and we reiterate the hope we expressed a year ago that the accustoming of the industrial population of this country to a habit of open-air life may be a permanent health asset in the future. With regard to the treatment of the discharged tuberculous soldier, Dr. ACLAND notes the fact that nearly one-half of these 2770 unfortunates had not received a pension. We have already commented on this glaring inequality of treatment, and we believe that the present Pensions Minister will not be content to allow its continuance. Now that for six months the Recruiting Boards have been categorically forbidden to take into the Army men who have been under treatment in a sanatorium or been notified as suffering from consumption, all men discharged from the Army suffering from tuberculosis must be regarded as having contracted their disability, if not their disease, during service, and should in justice be put in the way of earning their living again. No rigid scheme of pensions will cover these cases in common with the cases suffering from other physical disabilities. Dr. J. LUMSDEN tells us that as far as Irish soldiers are concerned they have probably all been offered sanatorium treatment before discharge from the Army but have generally refused such treatment. Dr. ACLAND holds that the sanatorium treatment should be voluntary and preceded by a period of furlough, but the chance of refusal and the discouraging experience of giving furlough to men discharged from military hospitals before entering convalescent camps are weighty reasons against it. Dr. LUMSDEN therefore would retain the tuberculous soldier in the service, compel him to go to a sanatorium, and not discharge him until he should be in a condition to take up work, suggesting an agricultural colony as an aid to the solution of the problem. We may remind our readers that Dr. E. H. R. HARRIES, whose contribution to the problem of the tuberculous soldier we published in THE LANCET of Dec. 2nd last, came to much the same conclusion from his study of more than 100 soldiers admitted to the Beechwood (Newport, Mon.) Tuberculosis Hospital for Soldiers. Dr. HARRIES summarised his points thus: (1) That sanatorium accommodation would be of much greater value if discharge from the Army were deferred; (2) that it should be followed by a further period of some months on a farm colony.

Light also is dawning on the general question of the treatment of tuberculosis in civil life. Even before the war it was beginning to seem impossible to lodge and feed at the expense of the National Insurance or other funds all the bearers of a chronic pulmonary lesion. Now, under the financial stress and lack of personnel due to the war, local authorities all over the country are failing to cope with their legal obligations to the chronic consumptive, and tuberculosis dispensaries have long, often

impossibly long, lists of patients waiting to go into sanatoriums. But the chronic case is not a responsive occupant of sanatorium beds, and the results do not seem to justify his preponderance there. A report just received by the North Riding Insurance Committee is typical of many others. Dr. D. DUNBAR assures the Committee that only about 5 per cent. of the inmates of the Aysgarth Sanatorium are permanently benefited, and it is becoming clear that sanatorium treatment in the strict sense is not even necessarily the best treatment for the chronic consumptive. Belief is steadily gaining ground in the increasing value of dispensary treatment at the hands of an expert tuberculosis officer and of domiciliary treatment by the panel doctor when the advice and collaboration of an expert are available. The Local Government Board evidently had this in mind in the recent issue of the Order for domiciliary treatment, which came into force at the beginning of this present year. This value is strikingly brought out by Dr. HENRY A. ELLIS, who relates in the same issue of the *British Journal of Tuberculosis* his favourable experiences of dispensary work in a large northern manufacturing town, contrasting them in frank surprise with his previous work at Coolgardie, in Australia, under vastly better conditions of fresh air and climate. He notes that for the working population surprisingly little increase of care is sufficient to re-establish their normal powers of resistance, and he is driven to the conclusion that the rigour of a scientifically directed tuberculosis treatment may be materially modified and reduced in most early cases in favour of a carefully conducted supervision of home conditions. Opinions supporting a similar view are expressed in the symposium by Dr. G. A. CRACE-CALVERT, who holds that the real treatment comes after the sanatorium when the patient has returned to home and work, and Dr. CECIL WALL, who emphasises the necessity for provision of satisfactory living conditions for those who have left sanatoriums and for laying more stress on the common-sense adaptation of their limited output of physical energy in the pursuit of a livelihood.

How real is the Scottish awakening to the dangers of tuberculosis is well illustrated by two occurrences in the House of Commons this week. A Supplementary Estimate for £27,000 has been laid before the House for the treatment of tuberculosis in Scotland, while a University Court Ordinance has been presented for the foundation in Edinburgh of a Chair of Tuberculosis.

#### THE LANCET, VOL. II., 1916: THE INDEX.

OWING to the continued shortage in the paper-supply the Index and Title-page to the volume of THE LANCET which was completed with the issue of Dec. 30th, 1916, have been printed separately, and copies have been supplied gratis to those subscribers who have intimated to us their wish to receive them. Other subscribers will be similarly supplied, so long as the stock remains unexhausted, on application to the Manager, THE LANCET Office, 423, Strand, London, W.C. Such applications should be sent in at once.

#### Annotations.

"*Ne quid nimis.*"

#### THE NEW YEAR HONOURS.

THE list of honours issued at the beginning of the year was a small one, and included the names of no medical men in their civilian capacity. A supplementary list issued early this week by the Prime Minister includes the names of Dr. Robert Armstrong-Jones, consulting physician on mental diseases to the Military Forces in London, who has received a Knighthood; Dr. Arthur Newsholme, C.B., Chief Medical Officer to the Local Government Board, who has been promoted to a Knighthood in the Order of the Bath; and Sir Robert William Burnet, physician to His Majesty's Household, who has been made a Knight Commander of the Royal Victorian Order. In the Foreign Office list appear the names of Dr. John Warnock, Director of Lunatic Asylums, Egypt, and Dr. William A. Betts, Director of Municipal and Local Committees of Egypt, both of whom have received a C.M.G. We offer these gentlemen hearty congratulations. Well-deserved honour has also fallen to Mr. E. M. Clarke, head of the motor ambulance department of the Red Cross, and to Mr. J. Grice, a well-known philanthropist and chairman of the Melbourne Hospital, who have received knighthoods; and to Mr. J. G. Griffiths, honorary secretary of King Edward's Hospital Fund for London, who has been promoted a C.V.O. Mr. L. J. Otter, Mayor of Brighton from 1913 to 1916, played a leading part in connexion with the war charities of the town, and his Knighthood is thoroughly well earned.

#### A RARE FORM OF WAR NEUROSIS.

THE latest number of the *Nouvelle Iconographie de la Salpêtrière* (No. 1, 1916-1917) contains a well-illustrated article by Madame Rosanoff-Saloff on a curious and uncommon condition supervening in certain neurotic subjects as a result of war trauma, mental or physical. This consists in a marked spinal curvature in an anterior direction, so that the patient comes to resemble the "Man with the Muck-rake." Similar cases have been also observed in this country. With this prominent anterior flexion of the trunk there is occasionally seen a lateral inclination. Dr. Souques, of the Hospice Paul Brousse at Villejuif, in whose neurological service the cases have been observed, proposes the term "camptocormia" for the condition, from καμπτω to bend, and κορμός the trunk. From the clinical point of view the attitude of the patient is identical with an anterior flexion of the trunk in a normal individual; in all cases, however, he exhibits transverse skin folds on the back of the neck from an effort to hold the head up and so augment the visual field and facilitate walking. The abdominal muscles can be seen to be strongly contracted underneath the skin. As a rule, most movements of the trunk can be executed with comparative ease, except that of extension or posterior flexion, an effort to perform which often results in a typical generalised tremor of the lower extremities. On the other hand, the majority of the cases can lie flat on their back in bed, and this dorsal decubitus is not even painful. If the patient, further, is put on his face in a recumbent position he can on request raise his head, showing that extension can in reality be

performed. As a fact, the spinal column is supple enough, nor is there any evidence of local vertebral pain or sensitiveness, with the exception of that produced by pressure and palpation of the lumbar musculature on either side. No other abnormality of the nervous system is found, while radiographic examination is invariably negative. The cerebro-spinal fluid is normal. Madame Rosanoff-Saloff has examined some 16 cases of this neurosis and divides them into two categories—those with actual wounds and those without. Only two of the series belonged to the first of these groups, and in them the wounds were far removed from the seat of the abnormal flexion. The great number of the other group occurred in soldiers who had been blown up by a shell or buried, with a loss of consciousness of variable duration. Occasionally actual lumbar ecchymoses were noted. In all the earliest symptom was lumbar pain, violent and continuous and aggravated by movement. From the point of view of pathogenesis it may be mentioned that the sole position of comparative comfort adopted voluntarily by such patients is that of bending the body forward till the head is between the knees. After some weeks of gradual relief from the pain they declare that they cannot get their back straight again, and all sorts of local treatment are as a rule unavailing. The persistence of the attitude is explained by the fact that the subjects of the affection are without exception neuropaths. The normal subject cannot adopt such forced positions for long because of their discomfort, whereas the neuropath maintains the attitude from ideational inertia or from auto-suggestion. Madame Rosanoff-Saloff states that the prognosis is perfectly good provided the patient is removed from the surroundings of the ordinary hospital, where little or nothing is likely to be done to combat the peculiar mentality on which the neurosis is erected. She pleads earnestly for the removal of such patients to special neurological centres at the front itself (*dans la zone des armées*), where appropriate medical treatment with rigorous military discipline soon effects the best results. The suggestion is made to place the patient in a plaster jacket, with or without an anaesthetic, keeping it in position for 8, 10, or 15 days. This treatment, coupled with an atmosphere that of itself suggests cure, and proper discipline, succeeds without fail, according to Madame Rosanoff-Saloff's experience. We find ourselves in entire agreement with the proposal that these and analogous cases should be treated at the front, in a military-medical environment, and not allowed the chance of becoming perpetuated by wandering from one hospital to another at home, where it is a mere chance they may meet with a physician who is sufficiently interested or leisured to devote himself to a cure. As Charcot said, "il ne faut pas laisser flâner les contractures hystériques."

#### THE WORK OF THE BELGIAN WAR REFUGEES COMMITTEE.

AMIDST the chaos of passion which war produces the organisation of charity has been particularly noticeable since the commencement of hostilities, and in no way more so than in the attempts to relieve the Belgian sufferers. When, by the ruthless destruction of Belgian towns, thousands of children, women, and men were rendered homeless and sought succour and shelter in this country, offers of help came from all parts and from all

classes, and in London so great was the demand to be of service that at one time the number of volunteers for work outnumbered that of the refugees. The report of the War Refugees Committee dated August, 1916, has just been issued, and tells the story of an organisation carried out under the greatest difficulties which has provided wholly or in part for some 200,000 out of probably 250,000 Belgian refugees who have entered this country since the beginning of the war. At the end of 1914 there were 2000 local committees engaged in the work, though this number has since been decreased to 1837. The offers of hospitality received by the various local committees made provision for some 150,000 people, while up to February, 1915, the Board of Trade Labour Exchanges had found work for 8752. The health department, which deals with hospital and convalescent treatment, maternity cases, the provision of surgical appliances, and the investigation of consumptives, has ministered to 2550 cases, the weekly average of new cases being 45. At the dispensary, which is managed by a committee of English and Belgian doctors assisted by a Voluntary Aid Detachment, 20,852 patients have received attention and 14,243 prescriptions have been dispensed at an average cost of 4d. per head. The domiciliary visits made numbered 550, the surgical appliances provided amounted to 518, and 2200 letters of recommendation to hospitals and other institutions were procured.

#### SHELL WOUND OF THE PREGNANT UTERUS.

UNDER the title "Cæsarean Section due to a Shell Fragment," MM. Saint, Goehlinger, and Poiré have described a remarkable injury due to the war of a kind which, fortunately, we are spared in this country. A woman, aged 33 years, in the sixth month of pregnancy, was taken to hospital. She lived in a town behind the British lines which was daily bombarded. While seated at her window a shell exploded in the street and wounded her in the lower abdomen. She was admitted three hours later. The abdomen was distended and a reaction of "peritoneal defence" was already marked on the right side. The uterus extended two finger-breadths above the umbilicus. The position of the foetus could not be ascertained by palpation because of the pain produced by examination. There was a wound of entry a little below and to the left of the umbilicus and one of exit 9 cm. away, two finger-breadths above the left crural arch. From each wound omentum projected. On palpation it was evident that the abdominal muscles were completely divided and that between the two wounds only a bridge of skin remained. Blood was abundantly escaping from the vagina. A digital examination was not performed. The pulse was 110 and good, and the general condition satisfactory. Operation was decided on. The bridge of skin between the wounds was divided and the usual median incision for laparotomy made below the umbilicus. This with the wound due to the injury itself gave a large triangular flap with its summit at the umbilicus. A wound in the fundus uteri, 5 cm. long, was found running from the middle line downwards to the left and forwards. Amniotic fluid and meconium were free in the pelvis. Without separating the edges of the uterine wound the lumbar region of a foetus could be seen on which a small wound was visible. A median incision in the uterus allowed a flap similar to that in the abdominal wall to be detached

and the foetus and placenta to be removed. As the foetus was thought to be dead attention was confined to the mother. The uterine cavity was cleaned out, the haemorrhage arrested, and the uterus sutured. After rapidly examining the coils of intestines the abdominal wounds were closed. At this moment the foetus, which had been left in a basin, began to cry. It was a female weighing 950 grammes and had a superficial wound 2 cm. long in the left sacro-lumbar region. After a warm bath the child was enveloped in cotton-wool, but only lived for 15 hours after the injury. The mother recovered without untoward incident. Evidently the gravid uterus prevented deeper penetration of the shell fragment into the abdomen and perforation of the intestine. The presence of the foetus may be held to have saved the life of the mother.

#### RESTRICTIONS ON THE USE OF MEDICINAL GLYCERINE.

THE Ministry of Munitions announces that owing to additional demands for glycerine for war purposes it has become necessary to place further restrictions on the issue of medicinal glycerine, and that supplies in future will be reserved for the manufacture of the preparations of the British Pharmacopoeia, and for such uses of special importance as may be sanctioned by the Ministry of Munitions. These supplies will, however, be small and must be used with the utmost economy. Applications for permission to obtain supplies should be addressed to the Director of Propellant Supplies, 32, Old Queen-street, Westminster, S.W., and should give the following particulars: 1. Quantity applied for. 2. Stock of glycerine held. 3. Purpose for which supply is required. (In case of Extra British Pharmacopoeia preparations formulae should be given.) 4. Applicant's average yearly consumption of glycerine for above purposes. 5. Name and address of proposed suppliers. The medical profession have been informed of the need for economy in prescribing glycerine, and it is anticipated that the requirements for dispensing will be greatly reduced. The stocks of glycerine in the hands of pharmacists should be sufficient to meet these reduced requirements, and therefore no glycerine will be issued for dispensing meantime. The surplus stocks held by pharmacists, and all stocks held by retailers who are not in a position to use them for these restricted purposes, should be disposed of either to other pharmacists who are short of stock or to wholesale houses for making B.P. preparations. We published a note last week on the importance of economising glycerine for medicinal use, and there can be little doubt that in many cases it can be replaced for dispensing purposes, without material disadvantage, by other substances.

#### THE DRESSING OF BURNS WITH PARAFFIN WAX.

Sir Arthur May's prompt application of the remedy to the requirements of the Navy has drawn fresh attention to the treatment of burns by a proprietary preparation called ambrine by its inventor, Dr. Barthe de Sandfort. As, however, the preparation is a secret one controlled by a company in Paris, the treatment is not as readily accessible as some of our correspondents desire. We can refer these to the experience of Lieutenant-Colonel A. J. Hull, R.A.M.C., who stated in the *British Medical*

*Journal* of Jan. 13th that the results obtained by a mixture of home manufacture in a military hospital have surpassed those obtained by the use of ambrine or any other preparation. He gives the following formula for its preparation:

Resorcin	1 per cent.
Eucalyptus oil	2 "
Olive oil	5 "
Soft paraffin	25 "
Hard paraffin	67 "

The hard paraffin is first melted and the soft paraffin and olive oil are stirred in. The resorcin is next added dissolved in half its weight of absolute alcohol, and finally the eucalyptus oil when the wax has cooled to about 55° C. If necessary, the resorcin may be replaced by a quarter of its weight of β-naphthol. Colonel Hull adds that the application of this No. 7 paraffin, as it is called, to ulceration following frost-bite has been as successful as in the case of burns. Other uses will doubtless suggest themselves for a soft impervious casing to wounds which can yet be readily peeled off without pain or disturbance to the delicate processes of repair.

#### BORIC ACID IN CREAM.

IN our issue of Oct. 28th, 1916, we referred to the Amending Order issued by the Local Government Board in regard to the use of preservatives in cream. The Order, as is now announced by the Local Government Board, comes into operation on April 2nd next. It temporarily forbids an addition of boric acid to cream of more than 0·4 per cent., but a small expert committee is to be appointed to inquire further into the desirability of using boric acid at all. In the meantime dealers are asked to make every effort to reduce the preservative to the smallest possible amount; or even to dispense with its use entirely. Until the results of the promised inquiry are known all prosecutions will be avoided in respect of the sale of preserved cream which complies with the Regulations as now amended. Further restrictions may possibly be made dependent upon the findings of the committee referred to. Instructions are issued as to the form of label which such preserved cream must bear. The presence and amount of boric acid must be declared, and the words "Not suitable for invalids" are to be added. A similar provision applies to the use of peroxide of hydrogen as a preservative, except that the amount present is not demanded to be stated.

#### THE SCIENTIFIC STUDY OF HYDROLOGY.

Dr. Fortescue Fox's paper on "The Future of British Spas," read last week before the Royal Society of Arts, was in effect a plea for the scientific study of physical remedies. He reminded his audience of the memorial laid before the University of London a few days before the outbreak of war, recommending the establishment of a University chair in medical hydrology and medical climatology, a proposal which was still before the Senate. Systematic teaching regarding the action and uses of waters of every kind, both within and without the body, is now available in other European countries. An institute of hydrology has recently been attached to the Collège de France. And it was the opinion of the memorialists in 1914 that authoritative teaching should be provided in London, as

the capital city of an Empire rich in climatic resorts and medicinal waters, for senior students and practitioners likely to specialise in this branch of practice, as well as for medical men who came from the country or from distant parts of the Empire. Laboratory facilities for research work upon British soil are also desirable. These considerations, already urgent in peace, had gained, Dr. Fox alleged, in weight and force from the experience of the war. He alluded to the place which physical remedies were taking in the restitution of disabled soldiers, and pictured a further extension of highly specialised forms of treatment. But where, he queried, were the specialists to be found? The "whirlpool bath" has found wide use for stiff and disabled limbs, and the success of the large "sedative pool" bath has been considerable in disordered action of the heart; but it is a mistake to suppose that one or two methods are applicable to all conditions, and the need of trained men who have studied the principles and practice of hydrological medicine is an immediate one. With Dr. Fox's views, as we have summarised them, we are in substantial agreement. The command depôts up and down the country are already giving striking ocular demonstration of the value of hydrological methods when dealt with on a scientific basis. The war has given a much-needed stimulus to this study, and the results will doubtless remain as a permanent therapeutic asset. Our British spas with their cool and bracing climate may well offer our friends across the Channel, as Dr. Neville Wood pointed out some years ago, a pleasant and healthful change from the heat of the continental summer. Well equipped with scientific practitioners of the whole art of applying water, they should offer a great and increasing attraction.

#### TYPE-READING BY SOUND.

AT the Röntgen Ray Society on Feb. 6th Dr. Fournier d'Albe demonstrated before a large audience an instrument which he has named an optophone, whereby, with practice, blind persons are, he says, enabled to read ordinary print by sound. The instrument depends upon an application of selenium, and before describing it the demonstrator dealt in a general way with the properties of selenium itself, which was discovered exactly a hundred years ago by Berzelius. He instanced many ways in which this substance had been turned to more or less practical account. It has been employed in photometry, in the release of automatic shutters in cameras, in multiplex telegraphy, in phototelegraphy (the transmission of photographic images across the wire), in the photographophone (in which cinematographic images and sounds are synchronised), in television, and in the automatic regulation of lights, signals, and buoys. The optophone, in which Dr. d'Albe is apparently most interested, is an instrument which he devised first in 1912 to enable sightless persons to locate bright lights or brightly luminous patches by means of the ear and to discover shadows intercepting the light. This result was obtained by placing two selenium preparations into two arms of a Wheatstone bridge, sending a galvanometer current through the telephone and interrupting it by a clockwork motor. The lecturer explained that the work had been delayed since the war began because of the impossibility of obtaining Nernst filaments, which

were essential because they gave an intense line of light; but he added that he had now found that the half-watt lamp was available as a substitute. A small, revolving, perforated disc is illuminated by the lamp, and the image of a line of luminous dots, furnished by this revolving disc, projected upon the type to be read; the light thus reflected from the type is passed to a set of selenium bridges connected by a telephone relay, and sounds corresponding to the various letters of the type are carried into the receiver. The current used is about 1 ma., but of 60 or 70 volts. Each letter of the printed matter, as it passes over the small aperture in the slab, gives, he says, a different sound effect from every other; whatever the difference in shape between any two letters, it expresses itself in a difference of tone which, with practice, the blind person would recognise. This sound alphabet, of course, has to be learned, but with practice the line of type can be moved across the aperture at the rate of several words a minute, and the sense becomes intelligible to the hearer. The maximum sound is heard in the telephone when the paper exposed is white and the minimum when it is black; therefore, what the sightless person has to learn are the variations between these two extremes. For demonstration purposes Dr. d'Albe used large printed letters, but he said that by a focussing arrangement the instrument could be adapted so as to make it possible to read type of ordinary size.

THE Hunterian lecture on Paget's Disease of the Nipple will be delivered in the theatre of the Royal College of Surgeons of England by Professor W. Sampson Handley to-day, Friday, Feb. 16th, at 5 P.M.

THE Milroy lectures of the Royal College of Physicians of London are to be delivered on Feb. 22nd, 27th, and March 1st by Dr. W. J. Howarth, his subject being "Meat Inspection, with Special Reference to the Development of Recent Years." On March 13th, 15th, and 20th Dr. G. A. Sutherland will give the Lumleian lectures of the College on "Modern Aspects of Heart Disease," and the Goulstonian lectures, with "Paratyphoid Infections" as their theme, will be delivered by Dr. C. H. Miller on March 22nd, 27th, and 29th. The time in each case is 5 P.M.

#### THE UNRESTRICTED DIET OF A SEDENTARY WORKER.

By A. D. WALLER, M.D. ABERD., F.R.S.

ABOUT three months ago, at the instigation of my friend Sir W. Osler, I took a summary measurement of my daily food during three days of my ordinary unrestricted diet. Sir William had banteringly reproached me with eating too much during war-time, saying that I must be a 5000 Calories man.

The figures for my three days' trial came out as follows. The decimals attached to these figures may seem absurd in connexion with such rough weighings; their appearance is due to the fact that the calculations were made on a Comptometer by my assistant, Mr. Shapiro. They serve the purpose of enabling the arithmetic to be checked by seeing whether horizontal and vertical lines give the identical final results in Calories. The first three columns give the percentages of Protein, Fat, and Carbohydrate assumed for calculation of the actual quantities of P.F.C. in the materials swallowed.

There are several points of interest in this series of summary observations. My average Calorie-consumption for the three days was 2471, inclusive of 227 Calories of claret and whisky, of which the calorific value is not undisputed.

Of the total 2471, breadstuffs constituted 840 Calories, which is equivalent to 334 grammes of breadstuffs—i.e., 5 lb. 3 oz. per week.

Of the 334 grammes of breadstuffs, 200 grammes were loaf bread and 134 grammes were puddings, &c.—i.e., 3 lb. 2 oz. of bread proper (loaf bread) and 2 lb. 1 oz. of other farinaceous foods.

100 parts of my bread materials were thus made up of 60 parts of loaf bread and 40 parts of other farinaceous materials.

I do not give my own case as representative, since I am 60 years of age, weigh 190 lb., and belong to the class of sedentary workers whose calorie requirements are considerably lower than those of the manual worker. I must, however, confess myself surprised that my Calories should be as low as 2244 (without alcohol). In my "Text-book of Physiology" I have given 3000 as the average Calorie requirements per working man per day for food as eaten, and that this should have as its foundation 1 lb. of bread per day (= between 1100 and 1200 Calories).

In the report by Dr. Leonard Hill to the Health of Munition Workers Committee the standard adopted is "about 3500 Cals. of food as purchased, and about 3000 Cals. as eaten." The average of five specimen diets at the end of the report comes out as 3111 Cals. as eaten. The proportion of bread to total in these diets is not given.

The ordinary prison diet—Diet B—adopted in 1899 on the advice of a Departmental Committee on Prison Dietaries, and now in operation, contains 3040 Calories, of which the bread, inclusive of flour and oatmeal, amounts to 2378 Cals., of which 1715 Cals. are afforded by 22 oz. per day of actual bread. On this diet, by courtesy of Sir Herbert Smalley, M.D., and of the authorities of H.M. Prison, Pentonville, I find as the result of the taking of the monthly weights of 107 cases that 82 per cent. of the prisoners gained weight, while 18 per cent. lost weight. This contrasts very favourably with the weight statistics previous to 1898 on the ordinary diet, which was then equivalent to only 2035, rising to 2579 Cals., under which 87 per cent. of prisoners suffered loss of weight.

## THE CONTROL OF VENEREAL DISEASES.

### *Syphilis in Paris.*

M. Gaucher, professor of medicine at the Hôpital Saint-Louis, in association with Dr. Bizard, gives some account of the prevalence of syphilis in Paris at the end of the second year of war. He begins with an instructive résumé which we may well reproduce:—

Before the war there were treated in the clinic 300 cases of recent syphilis out of 3000 cases of all kinds, a proportion of 1:10. In the first months of the war the figures were 800 out of 5000, or 1:6. In the following eight months, 600 out of 2300, or 1:4.

He deduces from these figures that the incidence of syphilis in general has increased in Paris by nearly two-thirds. Among civilians he has found an unaccustomed proportion of the very young and of elderly subjects. Out of 219 civilians, 37 were under 20 and 16 were over 50 years of age; and he reproaches these men with taking advantage of the absence of the men-at-arms to misbehave themselves. Among his military patients two-thirds were between 25 and 35 years, and out of 120 42 were married. This fact had produced a disastrous incidence of syphilis among married women, of whom, during a period of eight months, he had seen 120 (out of a total of 222 women) with recent syphilis. Professor Gaucher goes on to comment on the extraordinary frequency of gonorrhœa in addition to syphilis and to attribute both to the deficient enlightenment of both the public and the medical profession. Among the latter errors of diagnosis were almost the rule, and clinical instruction in venereal disease was therefore a first necessity. His colleague, Dr. Bizard, had recently addressed 22 conferences with 8000 men attending, as well

as five meetings of officers' training corps. Professor Gaucher sorrowfully records his experience that it is usual in France not to anticipate evils by prevention, but to await their occurrence before dealing with them, and he welcomes the recent appointment by the Minister of the Interior of a new commission to study the prevention of venereal diseases. His paper appears in *Paris Médical*.

### *Two Years' Experience of Arsenobenzol in France.*

In August of last year the Under Secretary of State for Military Hygiene addressed a questionnaire to the various military commands as to intravenous injections of arsenical preparations during the preceding period of two years. The replies have been summarised by M. Paul Ravant, médecin-major, in a recent number of the *Archives de Médecine et de Pharmacie Militaire* and afford statistical information of considerable value. The number of medical officers giving injections was 186 and the total number of injections given 94,762, of which all but 1537 were for syphilis. The preparations used were:—

	Times.
Neosalvarsan	35,826
Novarsenobenzol	37,352
Salvarsan and arsenobenzol	9,215
Ganyl	8,846
Luargol	3,523

The dose given was usually 0·6 to 0·75 gm., exceptionally 0·9, and even up to 1·5 gm. All began with a small dose. Salvarsan and arsenobenzol were always given diluted to 150 or 200 c.c. with saline; neosalvarsan and novarsenobenzol in a large proportion of cases in concentrated solution, often as little as 1 or 2 c.c. Ganyl and luargol injections ranged between 5 and 20 c.c. in bulk. No fatal case was reported among the 95,000 injections, but a military doctor reported having seen a Belgian soldier in a neighbouring service who died of arsenical intoxication after a dose of 0·3 gm. neosalvarsan, his death being attributed to arsenical idiosyncrasy. Of the more serious accidents observed, one man had transient coma, another delirium and epileptiform crisis (both after neosalvarsan), four had transient "nitritoid crises" (after ganyl), two had meningeal irritation and two facial paralysis (after neosalvarsan), two had epileptic crises, (neosalvarsan 1, ganyl 1). Albuminuria, always transitory, occurred in 11 cases (neosalvarsan 4, novarsenobenzol 2, salvarsan 1, ganyl 3, luargol 1), a passing icterus in 20 cases (in about the same proportion). One case of acute dermatitis followed a luargol injection, two cases were intolerant of neosalvarsan, which had in consequence to be discontinued. Local accidents were rare, abscess only occurred 4 times and was then attributed to faulty technique. The general criticism of the various preparations may be given in full:

Neosalvarsan: Very good.

Novarsenobenzol: Preferred. All find it at least equal to neosalvarsan, sometimes better. The incidents attendant on injection appear less frequent.

Salvarsan and arsenobenzol: Are considered very active. Have only been employed in default of the preceding, of which the injection is much simpler and more rapid. Only one doctor remained faithful to its use throughout.

Ganyl: Very active, according to some. Complaint is made of variations in manufacture, differences of solubility, and frequency of small accidents following injection. Owing to the last fact, a dose of 0·2 gm. has rarely been exceeded, which has diminished the efficacy of the treatment.

Luargol: Is arsenobenzol reinforced with silver and antimony. Some doctors find it extremely active. Complaint has been made that it has produced induration of the veins of the arm in consequence of too high a content of soda in the solvent.

An addendum records a fatal case, reported after the date of the inquiry, in a gunner 19 years of age, 48 hours after an injection of 0·9 gm. of novarsenobenzol. Coma was the first symptom, followed by convulsions and cyanosis. The necropsy revealed multiple congestion of all the organs, in particular of the brain. The reporting medical officer ascribed the accident to an ampoule of which the contents had deteriorated.

The report is a testimony to the remarkable safety of arsenical injections in skilled hands.

His Excellency the Chancellor of the Calcutta University has nominated Lieutenant-Colonel R. P. Wilson, F.R.C.S., D.P.H., I.M.S., to be an Ordinary Fellow of the University.

## NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

*Quinine Production and Investigation of Indian Indigenous Drugs.*

Lieutenant-Colonel Sir Leonard Rogers, I.M.S., was recently examined as a witness by the Industries Commission in Calcutta in regard to the production and manufacture of quinine. The cinchona plantations, he said, had been considerably extended in the Darjeeling hills, and the output of quinine increased. The last report showed that the plantations had been a sufficient financial success to render further extension advisable. The supply of quinine to treat the millions suffering from malaria in India was entirely inadequate, and the economic loss occasioned thereby in Bengal and other malarious parts of India was incalculable. Sir Leonard Rogers added that at present there was no professorship of pharmacology in India, and no considerable amount of original investigation of drugs had yet been carried out in the country. One such post had, however, been sanctioned for the School of Tropical Medicine after the war. Many indigenous drugs still required scientific investigation, and half a lakh of rupees had recently been given by the Maharaja of Darbhanga for this special work.

*Prison Improvement in Burma.*

Major H. H. G. Knapp, I.M.S., Inspector-General of Prisons, Burma, has been placed on special duty to visit the more important jails in the Madras, Bengal, and Bombay presidencies and in the provinces of Bihar and Orissa, the United Provinces, and the Punjab, to study the most recent methods adopted for the accommodation and reformation of prisoners and for the training of them for their return to ordinary life. The Governments concerned have offered him every facility.

*Scottish Women's Hospitals.*

Lord Carmichael presided recently at a meeting in aid of the Scottish Women's Hospitals for foreign service. Contributions of Rs. 80,000 were announced and it is hoped that two lakhs of rupees will be forthcoming.

*The Catherine Booth Hospital at Nagercoil.*

Inaugurated in 1900, this hospital has grown from a modest dispensary into a well-equipped institution with general and private wards covering seven acres of ground. Connected with the hospital are four branch institutions. The Maharaja of Travancore has built a new men's ward at a cost of Rs. 3500, while his Government has made frequent grants-in-aid.

*Death of Dr. B. K. Coomar.*

Dr. Bepin Krishna Coomar, the news of whose death from diabetic coma at the age of 67 has just reached this country, was one of the best known Bengali medical men. Entering Calcutta Medical College in 1868, he qualified in 1875 and became house surgeon to the Medical College Hospital, starting in private practice two years later. Dr. Coomar was an honorary magistrate, for several years a Commissioner of the Bali municipality, and an active member of the Indian Association for the Cultivation of Science.

Jan. 20th.

**THE SERVICES.****ROYAL NAVAL MEDICAL SERVICE.**

Staff-Surgeons to be Fleet-Surgeons : E. Cox, J. Macdonald, A. La T. Darley, A. J. Wernet, C. E. C. Stanford, A. R. Thomas, T. F. O'Keefe, R. F. Hills, D. V. Lowndes, P. F. Alderson, J. Thornhill. To be temporary Surgeons : B. L. Lloyd, N. H. Smith.

**ARMY MEDICAL SERVICE.**

Col. C. Birt is retained on the Active List, under the provisions of Articles 120 and 522, Royal Warrant for Pay and Promotion, and to be supernumerary.

Major Sir Edward S. Worthington, C.M.G., M.V.O., to be a Deputy Assistant Director-General, vice Lieut.-Col. G. St. C. Thom, C.M.G., who has vacated the appointment.

**ROYAL ARMY MEDICAL CORPS.**

To be acting Lieutenant-Colonels whilst in command of a Field Ambulance : Major J. W. H. Houghton, Major B. S. Bartlett, D.S.O., Brevet Lieut.-Col. Henry J. Crossley.

Temp. Major T. R. Hillott to be temporary Lieutenant-Colonel.

Major (temp. Lieut.-Col.) G. H. Ferguson relinquishes his temporary rank on reporting.

Major A. H. Burgess, R.A.M.C., T.F., to be temporary Lieutenant-Colonel.

To be temporary Lieutenant-Colonel whilst employed at the Grove Military Hospital, Tooting : E. W. Goodall.

Major R. G. Anderson is restored to the establishment.

Major (acting Lieut.-Col.) A. B. Hinde relinquishes his acting rank on reporting.

Temp. Capt. J. A. Torrens to be temporary Major.

To be temporary Captains : J. Watson, Surg.-Capt. H. J. Shone (Jersey Militia), H. E. Hobson (late temporary Captain, R.A.M.C.), E. C. Lindsay (late temporary Captain, R.A.M.C.).

To be temporary Honorary Captain : Temp. Hon. Lieut. H. A. F. Wilson.

Temporary Lieutenants to be temporary Captains : L. S. H. Gianville, W. Roche, J. S. Doyle, J. F. Wood.

Temp. Lieut. Charles C. Gibson to be temporary Captain.

To be temporary Lieutenants : J. B. Lester, C. W. Windsor, S. Marle, A. H. Bostock, A. McK. Niven, W. A. Smith, W. Hibbert, M. Crowley, C. B. Simpson, D. L. Morrison, T. Archdeacon, P. W. Ashmore, J. Reid, F. R. Tickle, A. Kirkhope, V. G. Ward, J. H. Pratt, G. P. Barff, H. S. McLellan, A. L. Gardner, A. K. S. Wyborn, W. Hartland, T. W. Arnison, J. H. F. Wilgress, W. E. Tanner, J. Howells, M. Hooper, H. L. V. Wemyas, W. H. Cam, F. Osborne, A. W. MacK. Sutherland, H. H. V. Welch, K. L. Bates, E. K. Campbell, J. M. N. S. Bickerton, E. Rommel.

The following relinquish their commissions : Temp. Hon. Capt. J. D. Lyle (having resigned his appointment at the British Red Cross Hospital, Netley), Temp. Hon. Capt. W. D. Copplestone (having resigned his appointment with the St. John Ambulance Brigade Hospital), Temp. Capt. B. C. Ashton (on appointment to Indian Medical Service), Temp. Lieut. W. M. Cromble (on appointment to Indian Medical Service), Temp. Lieut. T. Anwyl-Davies (on account of ill-health).

**SPECIAL RESERVE OF OFFICERS.**

To be Lieutenants : J. A. Panton (from Manchester University Contingent O.T.C.), N. C. L. B. Tweedie (from Belfast University Contingent O.T.C.), P. D. McLaren (from Edinburgh University Contingent O.T.C.), J. R. S. Mackay, D. J. Batterham and T. L. Heath (from University of London Contingent O.T.C.).

Lieutenants to be Captains : G. I. Evans, D. M. M. Fraser, R. S. Woods, G. S. Davidson, W. C. C. Haston, J. A. Mackenzie, W. N. Greer, D. G. Duff, A. McL. Ferrie, I. MacKenzie, E. A. Mills, C. Milne, J. Milne, C. P. Penberthy, M. Stewart, B. W. Fish, C. R. Knowles, R. S. Aspinall, D. S. Scott, N. H. Harrison.

**TERRITORIAL FORCE.**

Capt. (temp. Major) D. Dickie, D.S.O., relinquishes his temporary rank on alteration in posting.

Capt. A. S. Hobblethwaite, from West Riding Casualty Clearing Station, to be Captain.

Capt. H. N. Burroughes, F. Coleman, and S. F. Linton to be acting Lieutenant-Colonels whilst commanding a Field Ambulance.

Capt. W. H. Rothwell, from 3rd East Lancashire Field Ambulance, to be Captain.

Capt. E. H. Butler, from Territorial Force Reserve, to be Captain.

Capt. (temp. Lieut.-Col.) H. K. Dawson relinquishes his temporary rank on ceasing to command a Field Ambulance.

Lieut. A. G. Reid to be Captain.

Capt. G. C. Gray relinquishes his commission on account of ill-health contracted on active service and is granted the honorary rank of Captain.

Major (temp. Lieut.-Col.) P. R. Ash relinquishes his temporary rank on ceasing to command a Field Ambulance.

**URBAN VITAL STATISTICS.**

(Week ended Feb. 10th, 1917.)

*English and Welsh Towns.*—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18,000,000 persons, the annual rate of mortality was equal to 21.3, against 17.0 and 18.7 per 1000 in the two preceding weeks. In London, with a population of more than 4,000,000 persons, the death-rate was 22.2, or 2.4 per 1000 higher than that recorded in the previous week; in the remaining towns the rate ranged from 11.4 in Hornsey, 12.8 in Knfield, and 12.9 in Wimbledon and in Wakefield, to 33.5 in Brighton, 33.7 in Bath, and 34.0 in Wigan. The principal epidemic diseases caused 276 deaths, which corresponded to an annual rate of 0.8 per 1000, and included 89 from measles, 66 from diphtheria, 58 from infantile diarrhoea, 49 from whooping-cough, 9 from scarlet fever, and 7 from enteric fever. The deaths from measles, whooping-cough, and diphtheria were in excess of the average in the three preceding weeks; measles caused a death-rate of 1.6 in East Ham, 1.8 in Wimbledon, 1.9 in Barrow, and 4.2 in Wigan. The 801 cases of scarlet fever and the 1427 cases of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 17 and 3 less than the numbers at the end of the previous week. Of the 7058 deaths from all causes in the 96 towns, 274 resulted from violence. The causes of 90 of the total deaths were uncertified, of which 24 were registered in Birmingham, 13 in Liverpool, and 6 each in Preston and South Shields but only 3 in London.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death rate was equal to 17.9, against 16.9 and 17.7 per 1000 in the two preceding weeks. The 379 deaths registered in Glasgow corresponded to an annual rate of 17.7, against 22.2 per 1000 in London, and included 12 from whooping-cough, 10 from measles, 2 from diphtheria, and 1 each from scarlet fever and infantile diarrhoea. The 130 deaths in Edinburgh were equal to a rate of 20.4 per 1000, and included 5 from whooping-cough and 1 each from measles and infantile diarrhoea.

*Irish Towns.*—The 215 deaths registered in Dublin were equal to an annual rate of 28.1 per 1000, and included 6 from measles, and 1 each from diphtheria and infantile diarrhoea. In Belfast 240 deaths were recorded, equal to a rate of 31.8 per 1000, and included 2 from infantile diarrhoea and 1 each from measles, whooping-cough, and diphtheria.

AT the last meeting of the Chipping Sodbury board of guardians the salary of the district medical officer was increased by £20 in consideration of the high price of drugs at present prevailing.

## Correspondence.

*"Audi alteram partem."*

### THE DIFFERENTIATION OF HEART MURMURS IN SOLDIERS.

*To the Editor of THE LANCET.*

SIR,—Perhaps I may be permitted to make a few comments upon the letters that have appeared upon the subject of my letter in your issue of Nov. 4th, 1916. In the first place, may I remind your correspondents that the object of my communication was to call attention to a simple method by the practice of which I ventured to hope a common mistake might be avoided—I mean the mistake of confusing functional derangement of the heart with organic valvular disease—by means of the pressure test described.

I was pleased to have Dr. Leslie Thorne Thorne's corroboration and experience, and I may truthfully say that the more I have seen of these cases in returned soldiers the more convinced have I become of the value of the test. I must, however, insist upon the necessity for firm pressure, by which the ribs are pressed in by the fingers holding the bell-piece of the stethoscope, and their vibrations thus controlled as far as possible; for, unless this be done, some part of the functional bruit may persist and the observer be led into error.

In reply to Dr. A. Kinsey-Morgan, who questions the frequency of murmur in the cases under discussion, I must repeat that in my experience, derived from the control of medical wards containing upwards of 100 beds, they have been very frequent, though mutable and inconstant; in some, present alone in the recumbent position and altogether inaudible when standing, whilst in others the reverse order holds. In some the murmur is only audible when the patient is lying on his left side; in others, again, it ceases when he draws a long breath, and returns at the end of expiration. It is strange that Dr. A. Kinsey-Morgan should suggest that the bruit to which I referred was the so-called cardio-pulmonary murmur, a well-known type of functional murmur, for, as it happens, the cardio-respiratory bruit, as I have been accustomed to interpret the phenomenon, is, so far as I have been able to discover, the only functional murmur that has consistently withstood the effects of pressure.

I am indebted to Dr. Theodore Fisher for his remarks upon the causation of functional bruits, which greatly interested me; but I trust he will forgive me if I confine myself at present to their behaviour in response to the pressure test and its diagnostic value. I would say, however, that I do not think that the murmurs we render inaudible by pressure are caused by valvular leakage; in other words, I have not been able to regard them as endocardial. That they are the result of some functional disturbance in the cardiac muscle contractions producing vibrations communicated to the chest-wall is more than likely, and for this bruit I ventured to suggest in a paper published in *THE LANCET* in 1895 the name of neuro-typtic, compounded of neuron and typto. But it is obvious that this explanation will not cover the entire ground, though I would still regard them as exocardial—as opposed to valvular—murmurs. I may mention that the murmurs of dilatation are not rendered inaudible by pressure, nor are the bruits associated with and ascribed to anaemia (pulmonary systolic). But, on the other hand, systolic murmurs generated at the aortic orifice and conducted to the apex, and often mistaken for evidence of mitral regurgitation, may be arrested by pressure.

I am, Sir, yours faithfully,

Newcastle-on-Tyne, Feb. 3rd, 1917.

DAVID DRUMMOND.

### THE PHENOMENA OF ANAPHYLAXIS.

*To the Editor of THE LANCET.*

SIR,—I fear that I have already trespassed too much on your valuable space, but there is one comment that I should like to make on Captain S. Wyard's letter in your issue of to-day's date. If I understand him correctly, he suggests that the first case I reported, in which the patient received injections of antistreptococcal serum and a streptococcal vaccine, is not a true case of serum anaphylaxis, but is the result of

injecting anaphylatoxin produced by the action of the antistreptococcal serum on the streptococci. It seems to me impossible to accept such an explanation on the following grounds. In the classical experiments of Friedemann, Friedberger, and others on the *in vitro* production of anaphylatoxin, the methods adopted involved the action of considerable amounts of active complement on sensitised protein or bacteria. The various brands of antisera on the market, which have always been stored for some time before use, are in most cases almost destitute of active complement, or contain the mere trace. Again, the production in the test-tube of anaphylatoxin involves either prolonged action on ice or at room temperature or a moderate incubation time at 37° C. As I stated in my letter, the vaccine and antiserum were in this case mixed in the syringe immediately before use and therefore were only in momentary contact at room temperature before inoculation. It is, of course, theoretically possible that the antiserum might sensitise the bacteria so that they were subsequently acted upon by the patient's own complement. This explanation is, I think, completely ruled out by the results of the extensive use of sensitised vaccines, which are, by common consent, less toxic than the non-sensitised variety. There seems to be no reasonable doubt that the anaphylactic symptoms must be attributed in this as in the other cases to the action of the serum.

I was greatly interested by Captain Wyard's statement that the cases in which he had himself observed anaphylactic symptoms were those which had received a series of doses at short intervals. Since my last letter appeared Professor Leyton has very kindly called my attention to a series of observations published by him in the *Journal of Hygiene* in 1908, which bear a striking resemblance to those I reported. It seems to me that it would be of great value if those who are working with antisera would publish any results of the kind which they may have obtained, since at the present time it is most desirable that the risk involved should be accurately estimated.—I am, Sir, yours faithfully,

W. W. C. TOPLEY.

Bacteriological Department, Charing Cross Hospital,  
Feb. 10th, 1917.

### THE "TOXIC" EFFECTS OF METHYLENE-BLUE.

*To the Editor of THE LANCET.*

SIR,—It is generally admitted that the administration of methylene-blue has been followed by the most satisfactory results in the treatment of malaria and many other affections. In your issue of Dec. 23rd last appeared a note by Mr. Clifford Dobell and Dr. G. O. Low on the Treatment of *Lambia* Infections, in which it is stated that treatment by methylene-blue had to be discontinued owing to the "toxic" effects produced. In case any who might wish to employ this valuable remedy should be deterred from doing so by consideration of this finding, I desire to place before your readers the results of my experience in the use of methylene-blue.

Many years ago<sup>1</sup> in conjunction with Mr. F. W. Gee, I.M.S., I conducted a series of experiments, not only on natives of India but on British officers and others, with a view to ascertain the value of methylene-blue in the treatment and prophylaxis of malaria. Chloride of zinc is employed in the preparation of this drug, and the slightest trace of this or other impurity remaining in the finished product is apt to set up severe vesical and rectal irritation; the supply obtainable at that time in India was evidently impure, as we had many cases of retention of urine and severe tenesmus. During recent years I have, at home, employed methylene-blue in the treatment of many cases of various kinds without any complaints from the patients.

After reading Mr. Dobell's and Dr. Low's communication, with a view of testing the conclusions I placed a patient showing a heavy "*Lambia*" infection on 9 grains per diem of methylene-blue (3 grains with 1 grain extract, hyoscyami in the form of pill three times a day); in all 72 grains were given. The patient did not manifest the slightest discomfort, the general condition improved with increase of body weight, and regular

<sup>1</sup>On the Use of Methylene-blue in Malarial Fever, Indian Medical Gazette, xxviii., 1893.

examination of the stools showed a steady decrease in the number of cysts and free living forms. At present, only a very few cysts can be detected after prolonged search. One is forced to the conclusion that either in the case reported by Mr. Dobell and Dr. Low a pure sample of methylene-blue was not obtained or that the patient was peculiarly intolerant of the remedy.

To anyone who wishes to obtain pure methylene-blue I shall be glad to furnish the name of a drug-house, in Edinburgh, where a supply may be obtained which is "above suspicion."

I am, Sir, yours faithfully,

University of Edinburgh, Feb. 5th, 1917. D. G. MARSHALL.

## THE ASSOCIATION OF ATROPHY OF THE TESTICLE AND INGUINAL HERNIA.

*To the Editor of THE LANCET.*

SIR.—Two patients arrived from France recently with inguinal hernia and atrophy of the testicle on the same side as the hernia. The wasted testes were half as small as those of the opposite ones, and neither of the patients was conscious of this condition. Both of the atrophied testes were well descended in the scrotum. The rarity of this state points rather to a coincidental than a developmental condition. It has an important bearing to the surgeon, who may receive the credit of producing the abnormality, as after the operation the testes will still remain atrophied. I have pointed out the condition to each patient and have asked them to sign a statement that the testicle on the side of the hernia is much smaller than the other testicle. This will not prevent the unscrupulous or the ignorant passing an adverse criticism to suit their own purposes, but it will safeguard the surgeon in case of litigation.—I am, Sir, yours faithfully,

JOSEPH E. G. CALVERLEY, C.M.G., B.S. Lond.

Folkestone, Feb. 8th, 1917.

## PNEUMATIC TOURNIQUETS.

*To the Editor of THE LANCET.*

SIR.—The use of the sphygmomanometer armlet as an agent for obstructing the venous return when either venesection or intravenous medication is to be practised has probably occurred to many physicians. Dr. Hildred Carlill's letter in your issue of Feb. 10th confirms generally what has previously been written on the subject. Dr. J. Alfred Codd drew attention to the method in the *British Medical Journal* of Dec. 11th, 1915, and in the same journal on Jan. 29th, 1916, I ventured to add one or two practical points based on my own experience. One of these I should like to repeat, as I have seen the neglect of it lead to trouble. It is that the armlet prior to inflation should not grip the arm too closely—that, in other words, the constricting force should be provided solely by the air driven into the air-bag and not by the armlet band. Unless this is remembered the deflation of the air-bag at the moment the operation is completed will not entirely remove the obstructing pressure from the vein, and one of the consequences of this may be an unnecessary haematoma at the site of puncture. In short, the firm application of the armlet practised in taking the "blood pressure" ought to be avoided when the armlet is used to obstruct the venous return as a necessary preliminary either to venesection or to intravenous medication.

I am, Sir, yours faithfully,

Harley-street, W., Feb. 12th, 1917. C. O. HAWTHORNE.

## THE FIRST SCHOOL FOR MOTHERS.

*To the Editor of THE LANCET.*

SIR.—The article on child welfare work in THE LANCET of Jan. 27th mentions the year 1899 and refers to the foundation of the first school for mothers in the borough of St. Pancras "eight years later." An opportunity was given me to come up from Winchester, where I was then medical officer of health, to attend the opening meeting, which, if my memory serves, took place in the late spring of 1907.

From the annual report for 1906 on the health of the City of Winchester it appears that in November of that year—

.....arrangements were made for the notification of births by midwives within 14 days, the fee offered being 2d. for each birth, or 3d. if the notification also stated the weight of the child at birth. Midwives were supplied with copies of two pamphlets, one entitled "Advice to Mothers," the other

"How to bring up a Baby on the Bottle." Each pamphlet pointed out the advantages of periodical weighing and contained an invitation to mothers to bring their babies once a fortnight to be weighed on the corporation weighing machine. Tea is provided for the mothers gratis.

The mothers attending were advised by the medical officer of health, and the first client was secured some time in the last half of the month of November, 1906. The annual report dated April 16th, 1907, states that eight mothers were attending regularly, presumably on some earlier date when the manuscript of this section of the report was sent to the printer.

If you can find space for the publication of this letter it will serve to give to the corporation of the City of Winchester the credit which is due of founding the first school for mothers in this country.

I am, Sir, yours faithfully,

J. E. SANDILANDS,

Medical Officer of Health, Royal Borough  
of Kensington.

## STOCK MIXTURES AND PANEL PRACTICE.

*To the Editor of THE LANCET.*

SIR.—The annotation on Stock Mixtures in your issue of Feb. 10th might have laid more emphasis on two points in the circular.

1. The avoidance of deterioration is secured by the selection of the drugs and not by the addition of any form of preservative other than emulsion of chloroform, which appears to be employed more as a flavouring agent than on account of any special property, medicinal or otherwise.

2. Although the universal adoption of this list of stock mixtures will materially lighten the labours of pharmacists engaged in panel practice it is to be feared that, so far as the medical profession is concerned, while similarly reducing much routine, it must tend to diminish scientific progress and to limit the work of panel practitioners to the treatment of the most prominent symptom.

I am, Sir, yours faithfully,

Feb. 10th, 1917.

SOLlicitus.

## Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of Comitia of the Royal College of Physicians on Jan. 25th and of the Council of the Royal College of Surgeons on Feb. 8th diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon 83 candidates (including five ladies) who have passed the Final Examination of the Conjoint Board in Medicine, Surgery, and Midwifery, and have complied with the by-laws of each College. The following are the names and medical schools of the successful candidates:

Jugal Kishor Adhya, Calcutta Medical College and Middlesex Hospital; Adolfo Arias, St. Bartholomew's Hospital; Cedric Whitfield Armstrong, London Hospital; Eric Miles Atkinson, St. Bartholomew's Hospital; Henry Hamilton Bailey, Durham University and London Hospital; Kenneth Norman Grerson Bailey, St. Bartholomew's Hospital; Edwin Jennings Ball, Bristol University; Douglas John Batterham, Cambridge University and St. Bartholomew's Hospital; Leslie Graham Blackmore, Middlesex Hospital; Charles James Longworth Blair, St. Bartholomew's Hospital; Harold John Blamied, St. Thomas's Hospital; Charles Sidney Bluemel, Colorado University and University College Hospital; Duncan Campbell Bluet, Cambridge University and St. Thomas's Hospital; William Hallock Bradstock, Columbia University; Hilda Kathleen Brade, Manchester University; John Burke, Glasgow University and London Hospital; Patrick Alfred Buxton, Cambridge University and St. George's Hospital; Charles Herbert Carroll, London Hospital; Duncan Gillard Churcher, St. Thomas's Hospital; Alan Andreas Cockayne, Cambridge University and St. Thomas's Hospital; Cyril John Chesterfield Cooke, University College Hospital; Gunaratnam Franklin Cooke, Ceylon Medical College and St. Bartholomew's Hospital; Jean Cretin, St. Bartholomew's Hospital; Ahmed Tayel Dabbous, Westminster and Guy's Hospitals; Albert Victor Surgeon Davies, St. Mary's Hospital; Mahmoud Abu Bakr Demerdash, Cairo and University College Hospital; Harold Aylmer De Morgan, Middlesex Hospital; Alan Roy Dingley, St. Bartholomew's Hospital; John Reginald Keith Penning, London Hospital; Langdon Percival Firman-Edwards, Cambridge University and St. Bartholomew's Hospital; Arthur Alfred Fitch, Liverpool University and St. Bartholomew's Hospital; Frederick Christopher Ashley Frith, Bristol University; William Vincent Gabe, Middlesex Hospital; Aziz Girgis, London Hospital; Lionel Bernard Goldschmidt, King's College Hospital; Harry Goudge Grant, Dalhousie University and University College Hospital; John Richard Harris, Cambridge University and St. Thomas's Hospital; Geoffrey Arthur Harrison, Cambridge

University and King's College Hospital; Thomas Lowthian Heath, Guy's Hospital; Norman Sinclair Hewitt, Cambridge University and London Hospital; George Hoffmeister, Middlesex Hospital; Malcolm Cyril Joynt, Guy's Hospital; Edward Athol Clarence Langton, St. Bartholomew's Hospital; Felix Raoul Leblanc, Guy's Hospital; Annie Lloyd, Royal Free Hospital; Elbert Ralph Longstaff, St. Bartholomew's Hospital; Ronald William Lush, Oxford University and Middlesex Hospital; Howard Douglas McIlroy, Cambridge University and London Hospital; Kenneth Alexander Ingleby Mackenzie, Oxford University and St. Bartholomew's Hospital; Keith Masson, Cambridge University and St. Bartholomew's Hospital; Maurice William Holt Miles, St. Thomas's Hospital; Marie Mathilde Alice Moralt, Royal Free Hospital; John Branwell Mudge, St. Bartholomew's Hospital; Elizabeth O'Flynn, Royal Free and St. George's Hospitals; Edmund Stuart Orme, Cambridge University and St. Thomas's Hospital; John Allison Panton, Manchester University; Maurice Pearson, Guy's Hospital; Cyril John Penny, Cambridge University and Middlesex Hospital; Victor Felicien Clement Joseph Philippe, Brussels University; Frank Portas, Westminster Hospital; Arthur Abercrombie Prichard, Cambridge and Glasgow Universities; Ernest Digby Roberts, Lausanne University; James Paterson Ross, St. Bartholomew's Hospital; Kenneth Mackinnon Ross, London Hospital; George Harold Rosdale, Oxford University and St. Bartholomew's Hospital; Narendra Mohan Sen-Gupta and Mandell Shimbir, London Hospital; Raghunath Dadoba Shirwarkar, Bombay University and University College Hospital; Flora Nihal Singh, Calcutta Medical College and Royal Free Hospital; Charles Rees Smith, Guy's Hospital; Neville Harcastle Smith, Cambridge and Liverpool Universities; Vincent Russell Smith, St. Mary's Hospital; John Green Stevens, Guy's Hospital; David Stewart, Manchester University; Daniel Jenkins Thomas and John Herbert Thomas, University College Hospital; Wilfred Graham Verniquet, Cambridge University and St. Bartholomew's Hospital; Herman Crowther Viehoff, Liverpool University; Sydney Arthur Thomas Ware, St. Thomas's Hospital; Arthur Alward Watkinson, Charing Cross Hospital; Edward Williams, London Hospital; and Arthur Trevor Woolward, Cambridge University and London Hospital.

\* Diploma of M.R.C.S. granted Dec. 14th last.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—An ordinary meeting of the Council was held on Feb. 8th, Sir W. Watson Cheyne, the President, being in the chair. It was resolved to grant diplomas of Membership to 82 successful candidates, and in conjunction with the Royal College of Physicians of London to give diplomas in Public Health to six successful candidates. The Finance Committee reported that £23,900 had been invested in the War Loan, including £2,000 of new money. It was referred to the Finance Committee to consider the desirability of obtaining a loan for the purpose of further investment in the War Loan. Captain Raymond Johnson was elected a member of the Court of Examiners. Mr. Herbert Furnival Waterhouse was elected a member of the Board of Examiners in Dental Surgery. A letter was read from Lord Rhondda, President of the Local Government Board, stating that the suggestions made by the Council of the College on the subject of the treatment and prevention of venereal diseases will receive his careful and sympathetic consideration. A letter was received from Lady Eve thanking the President and Council for their kind expressions of sympathy in her bereavement. Sir John Bland-Sutton was appointed Bradshaw lecturer for the ensuing year.

Licences in Dental Surgery were conferred upon the following two gentlemen who have now complied with the requirements:—

Beresford Tom Richards, Birmingham University; and Reginald Joseph Ryland, Guy's Hospital.

**UNIVERSITY OF LONDON.**—At the First Examination for medical degrees, held recently, the following candidates were successful:—

Frances Dacre Alexander and Eleanor Mary Ashmall, London (Royal Free Hospital) School of Medicine for Women; Frederick Bach, London Hospital; Ormonde Alan Baker, University College; Gladys Liebs Buckley, Girton College; Dora Mahalski Cadman, London (Royal Free Hospital) School of Medicine for Women; Antoline Yves Cantin, London Hospital; Linda Catmur, Dorothy Spencer Chamberlain, Ivy Collier, and Annie Eveline Connan, London (Royal Free Hospital) School of Medicine for Women; Marguerite Etalline Cooke, private study; Rustam Nusserwanji Cooper, University College; John Alexander Currie, Guy's Hospital; Percy Tyson Davidson, Middlesex Hospital; Betty Dent, London (Royal Free Hospital) School of Medicine for Women; Conor John Donelan, St. Paul's School and St. Bartholomew's Hospital; Hilda Ray Dutton, University College, Exeter; Kerdwen Valentine Edwards, University College, Cardiff; Lucy Margaret Eison, Victoria University of Manchester; Rowland Henry Evans, University College, Cardiff; Geoffrey Edward Woolcombe Felce, Guy's Hospital; Emmie Dorothy Fenwick, London (Royal Free Hospital) School of Medicine for Women; Olive Gwendolin Fisk, Girton College; William John Gale, B.Sc., Battersea Polytechnic, South-Western Polytechnic Institute, and private study; Mark Garden, London Hospital; Lena Bella Gayer and Geraldine Norah Geary, London (Royal Free Hospital) School of Medicine for Women; Brian Wilson Barnett Gordon, Epsom College and St. Mary's Hospital; Barnett Gould, B.A., London Hospital; Marjorie Pearl Christine Greene, Roedean School; Stanley Allwright Gunter, St. Bartholomew's Hospital; Frederick James Simkin Hall, University College, Reading; Gertrude Eleanor Harre, Girton College and London (Royal Free Hospital) School of Medicine for Women; Elizabeth Merriman Heath, Marjorie Browning Hubert, and Irene

Esther Kenworthy, London (Royal Free Hospital) School of Medicine for Women; Oscar Bevan Lean, Bootham School; Jessie Levin, University College; Denzil Haydn Lewis, St. Mary's Hospital; Ivor Lewis, University College, Cardiff; Muriel Jessie Lough, B.Sc., Birbeck College; Mary Catherine Lynch, London (Royal Free Hospital) School of Medicine for Women; Ivan Bailey McCann, Guy's Hospital; Dorothy McNair, London (Royal Free Hospital) School of Medicine for Women; Edward Francis Malins, King Edward's High School, Birmingham; Harold Jordan Malkin, University College; Amis Mikhail, King's College; Emily Marjorie Milnes, London (Royal Free Hospital) School of Medicine for Women; Sybil Grace Vocatia (distinction in Inorganic Chemistry and Physics), King's College and London (Royal Free Hospital) School of Medicine for Women; Leslie Stuart Morgan, St. Bartholomew's Hospital; Doris Maude Odium, B.A., London (Royal Free Hospital) School of Medicine for Women; Winifred Catherine Piggott, Bootham School, Bedford College, and London (Royal Free Hospital) School of Medicine for Women; Mary Winifred Pitt-Lewis, Beatrice Myrtle Powell, and Gwenolen Mary Pratt, London (Royal Free Hospital) School of Medicine for Women; Margaret Annette Quine, Victoria University of Manchester; John G. Scott Reid, Epsom College and St. Thomas's Hospital; James Stuart Ricketts, King's College; Edith Margaret Ross-Johnson, Newnham College; Effie Frederike Amelia Samter, Victoria University of Manchester; B. Virginia Saunders-Jacobs, B.Sc., Newnham College; Alfred Senn, London Hospital; Christopher James Lewen Sharp, St. Paul's School; Thomas Archibald Shaw, Guy's Hospital and Mill Hill School; Abraham Isaac Silverman, Middlesex Hospital; Leonard Smalley, St. Thomas's Hospital; George Morris Stoker, Guy's Hospital; Edward Howard Strange, University College, Cardiff; William Hedley Summerskill, Guy's Hospital; Arthur Cleve Damian Telfer, St. Bartholomew's Hospital; Winifred Thompson, London (Royal Free Hospital) School of Medicine for Women; Estlin Hugh Weatherall (distinction in Biology), St. Bartholomew's Hospital; Leslie Ralph Augustus Wells, Guy's Hospital; Enid Margaret Williams, Swansea Technical College and King's College; Trevor Morgan Raleigh Williams, Swansea Technical College and University College; Henry Norman Witham, St. Thomas's Hospital; and Jacob Elias Zeitlin, London Hospital.

**Major R. W. Knox, D.S.O., I.M.S., has had conferred on him the Serbian decoration of the White Eagle.**

**CENTENARIAN.**—The death of Mrs. Hannah Lusted, of Lewes, at the age of 101, is reported.

The death occurred on Jan. 16th last of Mr. R. H. F. Rippon at Upper Norwood, where he had been resident for 36 years. He was 80 years of age, and for the past two years had been in receipt of a Civil List Pension of £100 per annum in recognition of his services to Natural History and Science.

**ROYAL SANITARY INSTITUTE.**—A discussion will take place to-day, Saturday, Feb. 17th, at 10.30 A.M., at the Town Hall, St. Helens, on Measures to be Taken to Prevent Contamination of Food by Flies. The discussion will be opened by Dr. Joseph Cates (medical officer of health), and the chair will be taken by Professor A. Bostock Hill.

**REGIUS PROFESSORSHIP OF PHYSIC IN DUBLIN UNIVERSITY.**—Our Dublin Correspondent writes: The vacancy in the Regius Professorship of Physic in the University of Dublin, caused by the death of Dr. James Little, has been filled by the appointment of Dr. John Mallet Purser, F.R.C.P.Irel. Dr. Purser was King's Professor of the Institutes of Medicine in the School of Physic from 1874 to 1901. His return to a position of influence in the University will please many generations of old Trinity College men.

**ST. MARK'S HOSPITAL, CITY-ROAD, E.C.**—The Lord Mayor of London, who presided at the eighty-first annual meeting of this hospital on Feb. 8th, in moving the adoption of the report, said that the accounts showed an adverse balance of £600, due in a great measure to the large number of war appeals and to considerable increase in the cost of everything connected with hospital administration. The need for this hospital was shown by the fact that it had treated 688 in-patients and nearly 1800 new out-patients during the year. Owing to the serious nature of the operations performed at this hospital a convalescent home is greatly needed, so that beds can be evacuated more quickly.

**NEW OUT-PATIENT DEPARTMENT AT THE ROYAL INFIRMARY, WIGAN.**—A memorial to the late King Edward, taking the form of a new out-patient department, was opened at the Royal Albert Edward Infirmary, Wigan, on Feb. 1st, by the Earl of Crawford and Balcarres, who, in an interesting speech on the progress of medical science, said that the success which the medical profession had achieved during the war was far in excess of anything that could have been predicted ten or even five years ago. The addition to the infirmary has been built at a cost of over £12,000, and represents the last of a series of extensions and enlargements which have been made at intervals since the foundation of the institution 40 years ago. As the new buildings were not begun till the beginning of the war their completion free from debt is an achievement of which Wigan may be proud.

# The War.

## THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

### Died.

**Major V. H. Symons, R.A.M.C.**, was educated at Birmingham University, and qualified in 1901. He had held appointments at the General Hospital, Birmingham, and in South Africa and Australia, and died at the Military Hospital, Tidworth, from an illness contracted in France.

**Major W. Wiley, R.A.M.C.**, was educated at Trinity College, Dublin, and qualified in 1903. After holding a house appointment at the Staffordshire General Hospital, he joined the R.A.M.C. in 1904.

**Dr. Isobel A. Tate**, who died whilst on duty at the Military Hospital, Malta, received her medical education at Belfast and at Dublin, qualifying in 1899, and had held several public appointments. Dr. Tate was acting as senior surgeon to Mrs. Stobart's medical unit in Serbia, but contracted typhoid fever and was invalided home just prior to the historical Serbian retreat.

### Wounded.

**Capt. J. A. C. Scott, R.A.M.C.**, attached Durham Light Infantry.

**Capt. J. M. Young, R.A.M.C.**, attached Highland Light Infantry.

**Capt. W. S. Evans, R.A.M.C.**, attached Royal Welsh Fusiliers.

**Lieut. R. A. Slater, R.A.M.C.**, attached Royal Field Artillery.

## OBITUARY OF THE WAR.

### HAMILTON MATHEWSON, M.B., B.CH. BELF.

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Temporary Captain H. Mathewson, who was killed on active service in November last, was 24 years of age and was the seventh son of the late Andrew Mathewson, Dunbunraver House, Newtownstewart, co. Tyrone. He received his medical education at Queen's University, Belfast, graduating M.B., B.Ch., B.A.O. in 1910. In the same year he was appointed senior assistant at the Portsmouth Infirmary, and two years later resident medical officer to the Norwich Infirmary, with care of the Children's Homes, Norwich. He was about to take the surgical Fellowship of the Scottish Royal Colleges in March, 1915, when he obtained a commission in the R.A.M.C. and went to France. He was slightly wounded in

September last, remaining, however, on duty, and on Oct. 23rd was dangerously wounded by a sniper as he was attending to a wounded man in front of the lines, and died four days later.

A colleague at the Norwich Infirmary writes of Captain Mathewson as an excellent organiser and possessing marked surgical ability, coupled with a quiet and unassuming manner which made him popular with the staff and governors.

### DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

**Capt. B. J. C. Dudley**, Dorsetshire Regiment, attached Nigeria Regiment, third son of Brigade-Surgeon Lieut.-Col. W. E. Dudley, of Bath.

**Capt. A. Lord**, Welsh Regiment, eldest son of Dr. R. E. Lord, of Colwyn Bay.

## THE HONOURS LIST.

The following awards to medical officers are announced:—

### Distinguished Service Order.

**Major John Edward Briscoe, S. African M.C.**

For conspicuous gallantry and devotion to duty. Although himself wounded, he continued to tend wounded men under very heavy fire. He set a splendid example of courage and coolness throughout.

### Bar to Military Cross.

**Temp. Capt. Kenneth William Mackenzie, M.C., R.A.M.C.**

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in conducting a hazardous and very difficult enterprise for the rescue of wounded from dug-outs in the newly-captured enemy trenches. He set a splendid example throughout.

(The award of the Military Cross was recorded in THE LANCET of Nov. 4th, 1916, p. 770.)

### Military Cross.

**Temp. Lieut. James Lang Cochrane, R.A.M.C.**, attached Gloucester Regiment.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in tending the wounded under heavy fire. He has on many previous occasions done fine work.

**Captain Arthur George Fisher, R.A.M.C., Special Reserve.**

For conspicuous gallantry and devotion to duty. He went forward to the front line under very heavy fire to locate some wounded men, whom he later succeeded in rescuing. He had previously done fine work.

**Capt. John Valentine Macdonald, I.M.S.**, attached Indian Army.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in attending to the wounded under very heavy fire. He had previously done fine work.

**Temp. Capt. Arthur John Rushton O'Brien, A.M.S.**, attached Gold Coast Regiment.

For conspicuous gallantry and devotion to duty. He repeatedly dressed and tended wounded men under very heavy fire. He set a splendid example of courage and coolness throughout.

**Temp. Capt. James Edmund Rutherford, R.A.M.C.**, attached Royal Irish Regiment.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in dressing the wounded under very heavy fire. He has on many previous occasions done fine work.

**Temp. Lieut. John Black Stevenson, R.A.M.C.**, attached Liverpool Regiment.

For conspicuous gallantry and devotion to duty. On four separate occasions he personally conducted stretcher-bearers through very heavy fire to succour wounded men. Later, although himself wounded, he continued to carry on his work.

**Temp. Capt. Roger Llewellyn Williams, R.A.M.C.**, attached S. Staffs Regiment.

For conspicuous gallantry and devotion to duty. He displayed marked courage and determination in tending the wounded under very heavy fire. He has on many previous occasions done fine work.

**Capt. Kenneth Alexander Gilchrist, S. African M.C.**

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in tending the wounded under very heavy fire. He set a fine example to those about him.

## MENTIONED IN DESPATCHES.

The names of the following medical officers are included in a despatch, dated Nov. 22nd, 1916, received from Lieut.-General the Hon. J. C. Smuts, Commander-in-Chief of the East African Forces:—

**Royal Navy.**—Temp. Surg. A. F. R. Woollaston. Staff, Headquarters, &c.—Maj. G. D. Maynard, S. Afr. Med. Corps; Lt.-Col. H. W. Vaughan-Williams, S. Afr. Med. Corps; Lt.-Col. J. H. Whitehead, S. Afr. Med. Corps.

**Royal Army Medical Corps.**—Capt. (temp. Maj.) J. A. Manifold; Temp. Capt. E. A. Gates.

**South African Medical Corps.**—Lt.-Col. T. Smyth; Lt.-Col. W. Field; Maj. J. E. Briscoe; Maj. H. S. Flock; Temp. Maj. J. Hunter; Maj. R. M. Truter; Maj. R. L. Girdwood; Maj. J. W. de Vos; Maj. C. M. Brothers (Dental Unit); Capt. (temp. Maj.) H. J. Orford; Capt. M. Heyns; Temp. Capt. K. A. Gilchrist; Capt. A. Groenewald, M.C.; Capt. N. J. Hofmeyr.

**Indian Medical Service.**—Maj. (temp. Lieut.-Col.) F. W. Sumner; Maj. E. T. Harris; Maj. A. Cameron; Maj. W. S. McGillivray; Capt. O. A. R. Berkeley-Hill; Capt. A. E. Grisewood; Capt. J. V. MacDonald.

**East African Medical Service.**—Capt. (temp. Maj.) A. D. J. B. Williams; Capt. A. A. H. Lawrence; Capt. J. C. Watt.

**Uganda Medical Service.**—Lieut.-Col. A. D. P. Hodges, C.M.G.; Temp. Maj. H. B. Owen.

**West African Medical Service.**—Temp. Capt. A. J. R. O'Brien.

**STAR AND GARTER HOME, RICHMOND.**—On Feb. 10th the Queen, on behalf of the British Red Cross Society, received the deeds of the land and building of the Star and Garter Home, together with those of Ancaster House, Richmond, an adjunct to the Home. Her Majesty also received £13,500 towards the endowment fund in addition to £18,000 the result of a collection among school children for a memorial to Jack Cornwell, V.C. This money will be used for the endowment of beds in the Home.

## THE CENTRAL MEDICAL WAR COMMITTEE.

The Central Medical War Committee, which sat for two days last week hearing appeals from the decisions of various Local Committees, pursued the same course this week. As had been expected, the appeals have grown steadily more numerous as the medical profession becomes thinned for military or naval purposes. Most of the medical men who were obviously free to take commissions have taken them, while a large number whom it is now sought to recruit can supply definite arguments for exemption. And it must be remembered that a certain proportion of them will later be rejected on physical grounds.

On Wednesday last the important piece of business before the Committee was the discussion of the actions taken, and to be taken, in accordance with the statement of the Director-General of National Service published in THE LANCET last week. Mr. Chamberlain, it will be remembered, said that it would be necessary "to see that the doctors are so mobilised and distributed that the needs of both the civil population and the Army can be met." It was reported at the meeting that an interview had taken place between certain members of the Central Medical War Committee and the Director-General of National Service on the subject of mobilisation of the medical profession as suggested by him in his general statement of his intentions. Mr. Chamberlain is now considering the terms of a communication laying the whole matter before members of the medical profession, and appealing to them to volunteer their services. It was felt by the Central Medical War Committee that the work which would fall upon it, should it receive a mandate to add to its previous activities others connected with the proposed general mobilisation of the profession, would necessitate addition to its central staff, and an interesting debate took place on the increase of the personnel of this staff. The great advantage which would result from strengthening the position of the Local Medical War Committees was insisted upon. There was a general feeling in the Committee that these local bodies were not always, or, perhaps, as a rule, used to the greatest advantage by the War Office, and that the War Office would greatly assist in the work of fair and adequate recruiting to meet the military needs of the country by ensuring that the medical military authorities in the various Commands at home should always be in close touch with the Local Medical War Committees for the districts within the area of each Command.

## BOOKS FOR BRITISH PRISONERS OF WAR.

The British Prisoners of War Book Scheme is the officially recognised medium for providing British prisoners of war with books for purposes of serious study. Those responsible for the working of the scheme are making urgent appeal for works on medical subjects to meet actual requests received from British prisoners, soldiers, sailors, and civilians, interned in enemy or neutral countries. Among the special books asked for at the moment are the following : "Diseases of Women" (Galabin), "Diseases of Children" (Goodheart and Still), "Materia Medica and Therapeutics" (Mitchell Bruce), "Medicine" (Osler), "Pharmacology" (Boumetz). All who can contribute one or more of the above works to this excellent War Charity are invited to forward to Mr. A. T. Davies, at the Board of Education, Whitehall, London, S.W., a list of the books they can offer. They will then be notified as to the acceptance of their gifts. Further particulars of the Book Scheme may be had on application.

**ARMY CANTEENS.**—The Army Canteens Committee has now assumed control of 1000 out of a total 1700 canteens in military barracks and camps, and negotiations are pending in regard to the remainder. Under the Committee's management the soldier will be the sole shareholder and 10 per cent. of the takings will be earmarked as an interim dividend for the canteen customers. Surplus profits are credited to the Central Regimental Institutes Fund from which £100,000 have already been given to the Star and Garter Hospital. The total annual turnover of the canteens at home is stated to be more than £15,000,000.

## Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

*The Parliamentary Session and the War.*

Parliament met on Wednesday, Feb. 7th. It is devoting itself almost exclusively to the war and the problems arising out of it. The House of Commons has discussed various matters affecting the food-supply. A vote of credit of £550,000,000 has been granted in Committee of Supply, which it is expected will carry on the war until the end of May. The Chancellor of the Exchequer's statement revealed the fact that expenditure had now reached an average of £5,790,000 a day. He placed the expenditure from the beginning of the war at £4,200,000,000.

*Criminal Law Amendment Bill.*

Sir GEORGE CAVE, the Home Secretary, has given notice that at an early date he will introduce in the House of Commons a Bill "to make further provision with respect to the punishment of sexual offences and the prevention of indecent advertisements and matters connected therewith." It is stated that one of the provisions of the Bill will make the communication knowingly of venereal disease a criminal offence. The expectation is entertained that the Local Government Board will bring forward a Bill at a later day to suppress the treatment of venereal disease by quacks and "secret remedies."

*Army Medical Boards.*

On the House of Commons going into Committee of Supply on Army Estimates, Mr. NIELD will call attention to the action of medical boards in passing recruits for service. He proposes to move "that, in the opinion of this House, the classification of recruits for the Army by military medical boards, particularly of men who have been previously examined upon attestation under the Derby scheme and rejected as unfit, has been productive of great and unnecessary hardship as well as expense by reason of the large number of such men, while undergoing training, being found unable to perform the military work required of them in the class to which they have been assigned, whereby they have had to be sent for hospital treatment and have occupied accommodation and medical attendance urgently required for returned wounded men; and this House is of opinion that an inquiry is urgently needed to alter and standardise these medical examinations and to ascertain the extent to which hospital accommodation and expense have been expended which with proper care might have been avoided."

## HOUSE OF COMMONS.

## MONDAY, FEB. 12TH.

*Wounded Prisoners in Switzerland.*

MR. HUME WILLIAMS asked the Foreign Secretary what was the present state of the negotiations with Germany with reference to the mutual repatriation of prisoners interned in Switzerland; whether there was any hope that badly wounded prisoners would be exchanged; and, if so, when they might be expected to arrive home.—MR. J. F. HOPE (for the Foreign Secretary) answered : The German Government have not yet definitely accepted our proposal for the repatriation from Switzerland of prisoners of war with disabilities which have developed since their transfer to Switzerland.

*British Prisoners in Turkey.*

Answering MR. HUME WILLIAMS, MR. J. F. HOPE said : His Majesty's Government has repeatedly made the strongest possible representations to the Turkish Government with a view to obtaining permission for representatives of the United States Embassy to visit the camps where British prisoners of war are interned. Their efforts until now have been unsuccessful, but they are being and will be continued. In the meantime certain camps have been visited by delegates of the International Committee of the Red Cross, whose report has not yet been received. The information which has been reaching His Majesty's Government from diverse sources is to the effect that the conditions under which the officer prisoners of war are interned are tolerable, but the situation of the prisoners of other ranks is in general deplorable.

## TUESDAY, FEB. 13TH.

*"Manipulative" Surgery.*

In answer to a question whether some of the leading exponents of "manipulative surgery" had offered to give their services free to suffering soldiers and their offers had been rejected, MR. MACPHERSON (Under Secretary for War) said that the rule was quite clear. Any man who was not on the Medical Register was not eligible for the Royal Army Medical Corps. The care, attention, and skill which had

been bestowed by members of the latter on men of the Army had been received with approbation on all hands.

#### Tuberculosis Treatment of Naval Officers.

Answering Mr. BRUNNER, Sir EDWARD CARSON (First Lord of the Admiralty) said: Naval officers who are admitted into hospital with pulmonary tuberculosis contracted on service are treated in a naval hospital at the expense of the Admiralty, unless they wish to be treated in an outside institution, when they have to undertake their own cure and treatment and the expense of such treatment. They are not invalidated after 91 days' treatment, but at the expiration of this period their full pay ceases and they are put on half-pay. These regulations have recently been brought to my notice, and in my opinion are not satisfactory, and the question of an alteration in the regulations affecting the care and maintenance of these cases is now before the Board.

## Appointments.

*Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

LEWIN, S. (temp. Capt. R.A.M.C.), and LOWRY, C. G. (temp. Capt. R.A.M.C.), have been appointed Assistant Surgeons to the Limbless Hospital, Belfast.

STEELE, PATRICK, M.D. Edin., Medical Superintendent of Roxburgh District Asylum.

Certifying Surgeons under the Factory and Workshops Acts: ELLISON, H. B., M.R.C.S., L.R.C.P. Lond. (Frodsham, Cheshire); JONES, T., M.R.C.S., L.R.C.P. Lond. (Amlwch, Anglesey); and KNOX, J. B., M.B., C.M. Edin. (Esher, Surrey).

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.*

APPLECROSS, PARISH OF ROSS-SHIRE.—Medical Officer, &c., for Torridon District. Estimated emoluments £350 per annum.

ASHTON-UNDER-LYNE, LANCS. DISTRICT INFIRMARY AND CHILDREN'S HOSPITAL.—Assistant House Surgeon. Salary £160 per annum, with usual emoluments.

BIRKINHEAD UNION INFIRMARY.—Junior Female Resident Assistant Medical Officer. Salary at rate of £300 per annum, with board, &c.

BOLTON INFIRMARY AND DISPENSARY.—Senior House Surgeon, Second House Surgeon, and also Third House Surgeon. Salaries £230, £200, and £180 per annum respectively, with board, &c.

BOURNEMOUTH, ROYAL VICTORIA AND WEST HANTS HOSPITAL.—Resident Medical Officer. Salary £250 per annum, with board, &c.

BRITISH RED CROSS HOSPITAL, Netley.—Two Medical Officers and One Surgeon

BURY INFIRMARY.—Junior House Surgeon. Salary £150 per annum, with board, &c.

CARDIFF, KING EDWARD VII.'S HOSPITAL.—House Surgeon for six months.

DERBYSHIRE ROYAL INFIRMARY, Derby.—House Physician and Casualty Officer. Also Resident Anæsthetist. Salaries £200 per annum, with board, &c.

DORCHESTER, DORSET COUNTY COUNCIL.—Temporary Clinical Tuberculosis Officer. Salary £250 per annum.

DUNDRE DISTRICT ASYLUM.—Assistant Resident Medical Officer. Salary £200 per annum, with board, &c.

DUNDEE MATERNITY AND CHILD WELFARE SCHEME.—Medical Practitioner (Female). Salary £35 per annum.

EDINBURGH PARISH COUNCIL, CRAIGLOCKHART POORHOUSE AND HOSPITAL.—Assistant Medical Officer. Salary £250 per annum, with board, &c.

EVERLINE HOSPITAL FOR CHILDREN, Southwark, S.E.—House Physician. Salary at rate of £160 per annum, with board, &c.

GREAT YARMOUTH HOSPITAL.—House Surgeon, unmarried. Salary £200 per annum, with board, &c.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £200 per annum, with board, &c.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—House Surgeon and Assistant Casualty Medical Officer. Salary at rate of £60 per annum, with board, &c.

KENNINGTON BOARD OF GUARDIANS INSTITUTION, Marloes-road.—Second Assistant Resident Medical Officer. Salary £160 per annum, with board, &c.

LEEDS PUBLIC DISPENSARY.—Resident Medical Officer. Salary £200 per annum, with board, &c.

MANCHESTER, BAGULEY SANATORIUM FOR TUBERCULOSIS.—First Assistant Medical Officer, unmarried. Salary £300 per annum, with board, &c.

MANCHESTER COUNTY ASYLUM, Prestwich.—Locum Tenens. Salary £7 7s. per week, with board, &c.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road.—Female House Surgeon. Salary £120 per annum, with board, &c.

MANCHESTER UNION, NELL LANE MILITARY HOSPITAL, West Didsbury.—Locum Assistant Resident Medical Officer. Salary £7 7s. per week, with board, &c.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—Junior House Physician. Salary £150 per annum, with board, &c.

PORTSMOUTH ROYAL HOSPITAL.—House Surgeon for six months. Salary £250 per annum, with board, &c.

QUEEN CHARLOTTE'S LIVING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £60 per annum, with board, &c.

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford.—House Surgeon.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Female Junior Obstetric Assistant. Salary £62 10s. per annum, with board, &c. Also to attend at Endsleigh-street Maternity Hospital. Salary £40 per annum.

ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Third House Surgeon. Salary at rate of £50 per annum, with board, &c.

ST. MARK'S HOSPITAL, City-road, E.C.—House Surgeon. Salary as arranged, with board, &c.

ST. PETER'S HOSPITAL FOR STONE, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £75 per annum, with board, &c.

Salford Royal Hospital.—House Surgeon and Junior House Surgeon. Salaries at rate of £200 and £150 per annum respectively, with board, &c.

STAFFORDSHIRE EDUCATION COMMITTEE.—Female Assistant School Medical Inspectors. Salaries at rate of £400 per annum.

SUNDERLAND ROYAL INFIRMARY.—Female House Surgeon. Salary £150 per annum, with board, &c.

UNIVERSITY OF LONDON.—External Examiners.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—Senior Resident Medical Officer. Salary £250 per annum, with board, &c.

WILLIMSDEN URBAN DISTRICT COUNCIL.—Temporary Assistant Medical Officer for the Health Department. Salary 28 8s. per week.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL.—Resident Medical Officer. Salary as arranged, with board, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notices of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Harefield and Rickmansworth.

## Births, Marriages, and Deaths.

### BIRTHS.

BLACKSTONE.—On Feb. 11th, at Westcliff-on-Sea, the wife of Leonard C. Blackstone, M.B., B.S., Temporary Lieutenant R.A.M.C., of a daughter.

CLARKE.—On Feb. 4th, at Belling-broke-grove, Wandsworth Common, the wife of Alexander Clarke, M.R.C.S., L.R.C.P., of a son.

MCGILLYCUDDY.—On Feb. 4th, at Compton-road, Wimbledon, S.W., the wife (née Lukey) of Captain R. H. McGillycuddy, M.C., R.A.M.C., of a son.

MURRAY-SHIREFF.—On Feb. 9th, at Whitley Cottage, Melksham, the wife of Cecil Murray-Shireff, L.D.S. R.C.S. Eng., of a daughter.

RIVETT.—On Feb. 10th, at a Nursing Home, to Louis Carnac Rivett, M.C., F.R.C.S., Clover Lodge, Dlike-street, Chelsea, and Mary (née R. wan)—a son.

STIHL.—On Feb. 10th, at Crescent-grove, Clapham, to Ruth, wife of Gavin Stihl, M.R.C.S., L.R.C.P., Temporary Captain R.A.M.C.—a daughter.

SUCKLING.—On Feb. 13th, at 5, Marine terrace, Margate, the wife of J. Jerome Suckling, M.B., B.S. Lond., of a daughter.

TINKER.—On Feb. 6th, at Bar Moor, Bletchingley, Surrey, the wife of F. Stanley Tinker, M.B., of a daughter.

### MARRIAGES.

BARKER—DAVIES.—On Nov. 4th, 1916, at St. Mary's Church, Quetta, Baluchi-stan, Captain H. L. Barker, I.M.S., to Jessie Gwendolyn, daughter of the late Daniel Davies, Ardigr-n, Wales.

MCREADY WORKMAN.—On Feb. 7th, at Downhill United Free Church, Glasgow, Captain Wilclf McReady, R.A.M.C., to Nellie B. Workman, youngest daughter of Mr. and Mrs. W. S. Workman, of University gardens, Glasgow.

TOWERS—HAK.—On Feb. 10th, at St. Thomas's Church, Edinburgh, Arthur Henry Towers, M.B., Ch.B., to Mila, only daughter of G. A. Hake, Lloyd's Register of Shipping, and Mrs. Hake, Leith.

YOUNG—BROUGH.—On Feb. 10th, at Holy Trinity Church, Southport, Captain William Francis Young, R.A.M.C., to Blanche Craig, youngest daughter of William Nelson Brough, of Liverpool and Southport.

### DEATHS.

HUTTON.—On Feb. 10th, at Weydown, Haslemere, H. R. Hutton, M.B. Cantab., aged 63 years.

KEATES.—On Feb. 7th, Courtney Cooper Keates, late Captain, R.A.M.C., aged 32 years.

SETON.—On Feb. 8th, at Onslow-road, Richmond, David Elphinstone Seton, M.D., in his 90th year.

SKINNER.—At Bridge of Allan, N.B., on Feb. 6th, Colonel Johnston Shearer, C.B., D.S.O., Indian Medical Service (retired), 10, Royal-terrace, Queen's Park, Glasgow.

WOON.—On Feb. 8th, at Dunbar, Russell Elliott Wood, M.B., C.M., F.R.O.S.E., Lieutenant-Colonel, R.A.M.C., Yeomanry, aged 62 years.

Mr. Percival Turner, of 4, Adam-street, Strand, regrets to announce the death, on Wednesday, Feb. 14th, of Miss Page, his trusted secretary, who was well known to his clients for over 21 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

### THE INVENTOR OF QUICK-FIRING GUNS.

IT must be more or less an accident that we have not got in early English history ample accounts of gunshot wounds. The quick-firing hand gun seems to be such a modern invention that it is curious to find that it is really 400 years old and that a King of England so closely connected with medical men as Henry VIII. should have been interested in the invention. In the little-known "Chroniques des Iles de Jersey, Guernsey, Aurgeny et Sark," it is related how—

Hellier De Carteret, Bailli de la dite Isle de Jersey, se transporta vers le Roy Henry VIII., auquel il remontra lo grief et injure que le dit Sire Hugh Vaughan, Capitaine de la dite Isle, luy avoit faite en Cour sainte, et comment le Roy luy confirma sa patente, touchant son office de Bailli soubs le Grand Seigneur d'Angleterre durant sa vie, et aussy le fist son Serviteur et Escuier tranchant, dont le dit Bailli fut sermenté solennellement aussy qu'en tel cas est requis et accoutumé. Et avecq ceulo le Roy donna congé et license ad dit Bailli, de tirer tant de la harquebuse que de l'archibaleste en quelque endroit que ce fust en tout le Royaume d'Angleterre, tant au gibier que es bestes sauvages sans aucunement en estre réprimé ni destourbé d'aucun durant sa vie; et de ce, luy en fis bonne assurance soubs son privé signe. Et fut le dit Sire Hugh Vaughan, Capitaine comme dit est, envoyé querir par un Herault d'armes en toute haste.

This giving by the King of a licence to use the harquebuse—the original hand-gun—was an exceptional privilege, as the British archers were thought highly of and encouraged.

The next few lines relate the invention by Hellier De Carteret of a quick-firing harquebuse, which would also aim in two directions at the same time, and King Henry VIII.'s interest therein. The greatest improvements in the harquebuse are generally credited to Filippo Strozzi, an Italian, in the year 1530.

Le dit Bailli estant aussy parvenu en la faveur du Roy par le moyen des Seigneurs du Conseil, et aussy que le Roy se délectoit fort à tirer tant de l'archibaleste que de la harquebuse, pouvoit ordinairement aller avecq le Roy quand il alloit tirer en quelqu'un de ses Parcs justes bestes sauvages ou autre gibier; et mesmement pour autant que le dit Bailli avoit trouvé une invention de tirer de la harquebuse 5 on 6 traits de bouleil l'un après l'autre et à plusieurs marques toutes d'une même charge l'une avant l'autre et d'un mesme feu, et aussy de son arba esto tirer deux vires tout d'un coup, l'une d'une voye et l'autre de l'autre et à deux marques. Le Roy voulut sevoir et apprendre la dite invention et l'expérimenter et pratiquer luy-mesme, à quel il y print un fort grand plaisir, tel ément que le dit Bailli fut de plus en plus en la bonne grace et faveur du Roy.

The wounds produced were so severe that a distilled aromatic spirituous liquor termed "harquesbusade" came into use for treating the shot wounds, and its composition was altered from time to time according to experience or fancy. The Seigneurs of St. Ouen, Jersey, have for so long a time been named De Carteret, that Philippe De Carteret who was the Seigneur in 1535 was the fifty-ninth Seigneur of St. Ouen, and the claim has been made that it would be difficult to find a race so old and direct in any kingdom.

### TEASPOONFUL MEASURES OF FOODS.

To the Editor of THE LANCET.

SIR,—In these days of food shortage we are all concerned with the measures and weights of foods. I have been interesting myself in discovering how many teaspoonfuls are contained in the avoirdupois pound of the following ordinary household foods and in some cases how many pieces to the pound. I find as follows, with a teaspoon measuring 97 teaspoonfuls to the pint (not a standard drachm):—

Tea .. . . . .	112	teaspoonfuls to the lb.
Cocoa .. . . . .	56	" "
Coffee beans .. . . . .	161	" "
Lump sugar .. . . . .	63	lumps (tenbes) ..
White granulated sugar .. . . . .	48	teaspoonfuls ..
Yellow crystals (moist) .. . . . .	36	" "
Rice .. . . . .	48	" "
Tapioca .. . . . .	64	" "
Scarlet haricot beans .. . . . .	48	" "
(Sift every dry) .. . . . .	44	" "
Flour .. . . . .	69	" "

(1602 beans).

From the above figures some deductions may be made. For instance, one pound of tea at 2s. 4d. lb. will make 112 cups. That is exactly one farthing per cup; and with two lumps of sugar at 6d. lb. (15 cubes for lb.) equals one-sixth of a penny; and with milk at 3d. a pint, three teaspoonfuls per cup equals one-tenth of a penny; total, a very small fraction over a halfpenny per cup (not including cost of gas for heating the water). It also shows that damp yellow crystal sugar (so-called "Demerara") heaps on the spoon and is not so economical as white crystals at the same price. It also shows that five lumps (tenbes) equals three teaspoonfuls of granulated sugar. The pound of haricots measured a pint,

and was bought at the grocer's. A pint of "butter beans" weighed only 13½ ounces, and there were 310 beans. A pound would have been 365 beans. The cost was the same—viz., 5d.—but the butter beans were bought at the cornchandler's, where measure and not weight is the rule. Other deductions may be made at pleasure.

I thought these measurements might interest your readers. The point to be remembered is that the exact size of the teaspoon must be arrived at first by the measure of its water contents, as a "teaspoon" is not a standardised measure.

I am Sir, yours faithfully,

London, Feb. 9th, 1917.

OBSERVER.

### THE SPRINGS OF THE MOTOR-CAR.

WE have received some letters from correspondents who depend upon their motors to get through their work and who are having unwanted trouble with the springs of their cars. Doubtless the present condition of the roads is not conducive to the life of any spring on any vehicle, but it is also a fact that though most owners, especially if also drivers, see to the lubrication of their engines, they rarely think of the condition of the springs. Springs are made of a certain number of laminations, the number depending on the weight of the car. As a result of their position they are exposed to a great amount of wet, with the inevitable result that rusting may set in and ultimately prevent the natural sliding movements of the leaves, so defeating the very purpose for which the springs were originally designed. The remedy is simple and thorough—it is also a troublesome one. It is to take the springs down occasionally and dismantle and grease each member separately. This operation is not generally done by any owners or drivers, with the consequence of occasional fractures and certainly less comfort in riding. "Messrs. Brown Brothers, Limited, of 15, Newman-street, London, W., have introduced spring gaiters, which cover the springs, retain grease, and ensure the constant lubrication which is essential to the action and life of this much-neglected member of the car's anatomy," writes a frequent correspondent on motoring, adding that he "is of opinion that the use of these gaiters will prevent to a great extent any trouble with springs."

### A CONUNDRUM IN RATIONS.

A LIFEBOAT containing 50 souls is afloat far from land; the probabilities are that it will not be picked up, but that it can reach land at the end of 14 days. The occupants of the lifeboat comprise: 5 A.B. sailors including, as an A.B., the ship's doctor, who takes command; 10 men passengers, of whom 4 are invalid; 15 women, of whom 3 are "as strong as men"; 20 children. The provisions in the boat are as follows: one puncheon of water, one anker of rum, 400 lb. of bread, 250 lb. of meat, 75 lb. of sugar.

The doctor decides at once to ration these provisions. What scale will give him the best chance of bringing his charge to land without loss of life?

### A CENTENARIAN DESCENDANT OF OLD PARR.

A RECENT issue of *The Friend* contains some interesting particulars of Sarah Ann Alexander, of Reigate, who completed her 100th year on Jan. 15th. She is the last survivor of a long-lived family of eight brothers and sisters, one of whom died at the age of 103, the ages of the others varying from 88 to 93 years. Her mother's family claimed descent from Old Parr, who died at the age of 152. The portrait of Miss Alexander, when aged 100, shows a fine type of old age. In the same paper the death is announced, at the age of 105, of Elizabeth Tozell McCoy, of Bloomington, Indiana, another member of the Society of Friends.

### EDIBLE SEAWEED.

To the Editor of THE LANCET.

SIR,—Referring to your interesting note in THE LANCET of Feb. 10th on "Edible Sea Plants," it may interest you to know that in East Anglia "samphire" is eaten; but on investigation this proves to be not the true samphire, but *Salicornia herbacea* (Chenopodiace); it grows on the salt marshes about here, and is pickled for eating.

I am, Sir, yours faithfully,

Melton, Suffolk, Feb. 12th, 1917.

JAMES R. WHITWELL.

### CHILD WELFARE CHARTS.

We have received from the secretary of the National League for Physical Education and Improvement a specimen of a very practical chart (1s. per dozen, 6s. per 100) for recording the weight of the child during the first 5 years of life. In the first year the record is weekly, in the second monthly, and in the third to fifth inclusive quarterly. The course of normal weight is indicated. Two useful wall charts are also issued (20 x 30 in., price 2s. post-free): one indicating the dangers of the "comforter," the other showing graphically the hours of sleep desirable at different ages. The charts should be of real help to welfare workers, and may be obtained from the offices of the National League, 4, Tavistock-square, London, W.C.

## Medical Diary for the ensuing Week.

### SOCIETIES.

**ROYAL SOCIETY**, Burlington House, London, W.

THURSDAY.—Papers:—Mr. S. A. Smith: The Fossil Human Skull found at Talgal, Queensland (communicated by Prof. G. E. Smith).—Dr. C. Chree: The Magnetic Storm of August 22nd, 1916.—Prof. W. H. Young: On the Ordinary Convergence of Restricted Fourier Series.

**ROYAL SOCIETY OF MEDICINE**, 1, Wimpole-street, W.

#### MEETINGS OF SECTIONS.

Tuesday, Feb. 20th.

**GENERAL MEETING OF FELLOWS**, at 5 p.m.  
Ballot for Election to the Fellowship.  
(Names have already been circulated)

**THEAPEUTICS AND PHARMACOLOGY** (Hon. Secretaries—W. Langdon Brown, Philip Hainill, J. Gordon Sharp): at 4.30 p.m.  
*Paper:*

Dr. Stansfeld: The Principles of Treatment by Transfusion of Blood.

Wednesday, Feb. 21st.

**HISTORY OF MEDICINE** (Hon. Secretaries—J. D. Rolleston, Charles Singer): at 5 p.m.  
*Exhibition of Portraits, Books, &c.* (at 4.30 p.m.).

*Paper:*  
Dr. R. Hingston Fox: The Medical Practice of Dr. John Fothergill (1740–1780).

Friday, Feb. 23rd.

**STUDY OF DISEASE IN CHILDREN** (Hon. Secretaries—A. S. Blundell Bankart, E. A. Cockayne, C. P. Lapage): at 4.30 p.m.  
*Cases:*

Dr. J. Porter Parkinson: Case for Diagnosis.

Dr. T. R. Whipham: (1) Precocious Sexual Development; (2) Frigilitas Femina.

#### Pathological Specimens:

Dr. Eric Pritchard:

Dr. E. A. Cockayne: Case of Defect of Duodenum.

*Short Papers:*  
Mr. J. S. Kellett Smith: Some Points in Lateral Curvature of the Spine.

Dr. F. Parkes Weber: Lipodystrophy Progressiva.

**EPIDEMIOLOGY AND STATE MEDICINE** (Hon. Secretaries—William Butler, M. Greenwood, jun.): at 8.30 p.m.  
*Paper:*

Mr. A. W. Bacot (Lister Institute): The Louse Problem.  
The discussion will be opened by Professor G. H. V. Nuttall, F.R.S.

**ROYAL SOCIETY OF ARTS**, John-street, Adelphi, W.C.

MONDAY.—4.30 p.m., Cantor Lecture:—Prof. A. B. Pite: Town Planning and Civic Architecture. (Lecture IV.)

**ILLUMINATING ENGINEERING SOCIETY**, House of the Royal Society of Arts, John-street, Adelphi, W.C.

TUESDAY.—5 p.m., Dr. J. Kerr: The Effect on the Eye of Varying Degrees of Brightness and Contrast.

**LONDON DERMATOLOGICAL SOCIETY**, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY.—5 p.m., Paper:—Dr. C. Kempster: The Action of X Rays upon Diseases of Bacterial Origin.

**ROYAL MICROSCOPICAL SOCIETY**, 20, Hanover-square, W.

WEDNESDAY.—Dr. A. H. Drew and Dr. Una Griffin: Parasitology of Pyorrhœa.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON**, Pall Mall East.

THURSDAY.—5 p.m., Milroy Lectures:—Dr. W. J. Howarth: Meat Inspection, with Special Reference to the Developments of Recent Years. (Lecture I.)

**ROYAL COLLEGE OF SURGEONS OF ENGLAND**, Lincoln's Inn Fields, W.C.

MONDAY AND WEDNESDAY.—5 p.m., Hunterian Lectures:—Prof. R. H. Elliot: Couching for Cataract in India.

**POST-GRADUATE COLLEGE**, West London Hospital, Hammermith-road, W.

MONDAY.—2 p.m., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 p.m., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 a.m., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Partoe: Operations.

THURSDAY.—2 p.m., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 a.m., Dr. Simson: Gynaecological Operations. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 a.m., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Partoe: Operations.

**ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN**, 49, Leicester-square, W.C.

THURSDAY.—6 p.m., Chesterfield Lecture:—Dr. M. Dockrell: The Papular Eruptions.

**ROYAL INSTITUTION OF GREAT BRITAIN**, Albemarle-street, Piccadilly, W.

TUESDAY.—3 p.m., Prof. C. S. Sherrington: Pain and its Nervous Basis. (Lecture VI.)

**ROYAL INSTITUTE OF PUBLIC HEALTH**, Lecture Hall of the Institute, 37, Russell-square, W.C.  
Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY.—4 p.m., Lecture VI.:—Dr. T. D. Lister: The Tuberculosis Problem in War Time. Dr. T. D. Acland, Dr. T. N. Kelynack, and Dr. C. Wall have promised to take part in the discussion.

### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To the EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

We cannot prescribe or recommend practitioners. Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

Offices: 423, STRAND, LONDON, W.C.

### MANAGER'S NOTICES.

#### VOLUMES AND CASES.

VOLUMES for the second half of the year 1916 will be ready shortly. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half-year's numbers (inland edition) are now ready. Cloth, gilt lettered, price 2s., by post 2s. 4d. To be obtained on application to the Manager, accompanied by remittance.

#### ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8d. The rates of subscription remain as revised in October.

#### INLAND.

One Year ...	... ...	... ...	... £1 10 0
Six Months	... ...	... ...	... 0 16 0
Three Months	... ...	... ...	... 0 8 0

#### COLONIES and ABROAD.

One Year ...	... ...	... ...	... £1 12 6
Six Months	... ...	... ...	... 0 17 6
Three Months	... ...	... ...	... 0 8 9

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

#### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

#### ADVERTISEMENT RATES.

Books and Publications	... ...	... ...	Five lines and under ... ... 4s. Od.
------------------------	---------	---------	---

Official and General Announcements	... ...	... ...	Every additional line, 6d.
------------------------------------	---------	---------	----------------------------

Trade and Miscellaneous Advertisements	... ...	... ...	Per additional 8 words, 6d.
--	---------	---------	-----------------------------

Situations Wanted	... ...	... ...	Quarter Page, £1 10s. Half a Page, £2 15s.
-------------------	---------	---------	--

Entire Page, £5 5s.	... ...	... ...	Special terms for Position Pages.
---------------------	---------	---------	-----------------------------------

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

## METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Feb. 14th, 1917.

Date.	Rain-fall.	Solar Radio in Vaono.	Maxi- mum Temp. Shade.	Min. Tem.	Wet Bulb.	Dry Bulb.	Remarks.
Feb. 8	...	57	36	24	28	28	
" 9	...	59	39	25	27	27	Fine
" 10	...	44	37	27	33	34	Fine

## Hunterian Lecture

ON

### DUPUYTREN'S CONTRACTION OF THE PALMAR FASCIA: DUPUYTREN'S LIFE AND WORKS.

*Delivered at the Royal College of Surgeons of England on Feb. 12th, 1917,*

BY J. HUTCHINSON, F.R.C.S. ENG.,

HUNTERIAN PROFESSOR AND EXAMINER IN SURGERY TO THE COLLEGE; SENIOR SURGEON TO THE LONDON HOSPITAL.

MR. PRESIDENT AND GENTLEMEN.—In long-standing and severe cases of Dupuytren's contraction, certainly all those in which the affected digits are rigidly bent into the palm, the surgeon who trusts to the operations hitherto in vogue will be disappointed. Whether he divides or excises the palmar fascia he cannot straighten the contracted finger by manual force, still less can he trust to this being effected by subsequent splint-pressure, however prolonged.

#### CAUSATION OF CONTINUED CONTRACTION AFTER OPERATION.

What is it that prevents extension of the contracted fingers after the fascia has been thoroughly divided or excised? Obviously the skin will not account for this failure, and there are three other possible explanations:—

1. The one most generally assigned is a consecutive contraction of the flexor tendons. These have often been divided in the vain hope that the resistance would then be overcome. But it is easy to prove, without this useless test, that the fault does not lie in the tendons, for full flexion of the wrist or metacarpo-phalangeal joints makes no difference at all. This is conclusive, as thereby we relax thoroughly both flexor profundus and sublimis.

Before Dupuytren discovered the real cause of the contraction, which ever since has borne his name, the view chiefly held was that the flexor tendons were to blame, and it is curious to find traces of this exploded view surviving still. Nothing is, however, more certain than their innocence of any share in producing or keeping up the deformity, except that slight flexion of the fourth and fifth digits at the first interphalangeal joint is the normal position of rest. The possible relation of this fact to Dupuytren's contraction is discussed later.

2. Intra-articular adhesions in the metacarpo-phalangeal and interphalangeal joints of the contracted fingers might be invoked as the cause of the resistance, especially by those who see a close relation between this condition and gout or rheumatism. The idea of the existence of these adhesions is also favoured by the grave danger of stiffening of the fingers during the splint-treatment ordinarily pursued after operation, a danger which can hardly be impressed too strongly.

It would be difficult to disprove the theory of adhesions in the finger-joints without the aid of the X rays. But reference to Fig. 4, which may be taken as a typical instance of Dupuytren's contraction, shows a perfectly smooth articular surface in each joint. In the specimens I have obtained by operation (excision of the first inter-

phalangeal joint) the joint surfaces were always found to be normal. Both the explanations suggested are therefore seen to be groundless. The true reason is that, owing to the second phalanx being extremely flexed so that its base is pressed against the neck of the first phalanx, and, owing to this position being kept up during many months or years, the glenoid ligament in front of this joint, as well as the lateral ligaments, become shortened and incapable of extension.

#### TREATMENT.

The only way to overcome this obstacle is to excise the head of the first phalanx. Briefly the method is as follows:—

1. Through a palmar incision the bands of contracted and thickened fascia are dissected out, including their prolongations in front of the first phalanx (the best form of incision will be discussed later). The palmar wound or wounds are closed with the finest black silkworm-gut. The finger still remains flexed at the first interphalangeal joint.

2. The hand is turned over so that the dorsal surface is uppermost, a semilunar incision is made over the first interphalangeal joint, the extensor tendon divided, the head of the first phalanx cleared to its neck, the latter cut across and the head dissected out.

3. The extensor tendon is slightly shortened and its two ends united, preferably with fine kangaroo tendon or Japanese silk, and the small dorsal incision (which is, of course, quite separate from the palmar one) is then sewn up. The finger should now become perfectly straight (or nearly so) without any tension whatever.

4. No splint is required in the after-treatment, the gauze dressing is a sufficient support, gentle active and passive movements should be resorted to within the first few days. *No digit should be allowed to stiffen.*

I attach equal importance to two points—namely, the excision of the first phalangeal head and the avoidance of the prolonged and irksome splintage usually resorted to. The latter has been responsible, as will be illustrated later, for many stiff fingers and hands following the orthodox operations, and I believe it is to some extent also responsible for the well-known tendency to recurrence of the contraction after them.

The following case illustrates how excellent a result can be obtained by the method advocated without the employment of any splint in the treatment from beginning to end, formed at the site of the excision.

The patient was a man, aged 54. His right little finger was alone affected, but was bent right into the palm. I dissected out the band of palmar fascia thoroughly, but found it impossible to alter the deformity materially. I then excised the head of the first phalanx, shortening the extensor tendon and uniting it by fine kangaroo-tendon sutures. The finger came practically straight without tension; aseptic dressings were applied without a splint.

He was back at work very soon, and Figs. 1 and 2 show in a perfectly unbiased way the result several months later. The upper figure shows his hand in voluntary extension; the little finger is the least bit bent at the two digital joints, but this is no more than is habitual with many people who possess normal hands. In fact, it may be termed a normal position of rest for the little finger.

In flexion it will be noticed (Fig. 2) how good is the movement at the new joint; his grip was strong in all the fingers. Practically no sign of the small dorsal scar could be detected,

the palmar one was very inconspicuous. Here I would note that in some cases where forcible stretching of the finger has had to be employed by the surgeon during and after his operation the palmar scar becomes thick, disfiguring, and uncomfortable when the patient uses his hand. The well-known pathological law is illustrated that intermittent pressure and irritation of tissues always cause hypertrophy. It is just this hypertrophy that we have to dread and avoid in our treatment of Dupuytren's contraction.

The photograph shows the very slight degree of shortening of the digit produced by excision of the first phalangeal head. The normal relative length of the different digits is variable and of no importance. A slightly shortened but thoroughly useful finger is a very different thing from a stiffened and useless one.

It must not be claimed that a perfect result, functional and cosmetic, can be obtained in every case of Dupuytren's contraction, owing to the extreme length of time which is sometimes allowed to elapse before operative aid is sought. This point is illustrated by the following case.

A man, aged 54, was treated for Dupuytren's contraction of the ring finger, of no less than 10 years' duration. (Fig. 3.) Excision of the band of palmar fascia made no difference to the deformity. I then removed the head of the first phalanx and the finger came straight. But though the deformity was thus removed, the other two joints had stiffened during their 10 years' rigidity, and a perfect functional result could not therefore be obtained.

#### HISTORY OF VARIOUS METHODS OF TREATMENT.

A few words must be devoted to the history of the various methods of treatment in Dupuytren's contraction. Prior to the publication of the French surgeon's accurate pathological account of the disease in his "Leçons Orales" (vol. i., 1832) there was no treatment worth mentioning for the condition. Thus, Sir Astley Cooper simply referred to it as incurable. Dupuytren, having proved that the palmar fascia was to blame, advocated open transverse division of the fascial bands, the wounds being allowed to heal by granulation. Three cases only are described in his account; they were said to have been cured, but no surgeon at the present time would employ this method or hope for a cure to result from it.

Then came, with the wide use of tenotomy for club-foot, &c., the introduction of the subcutaneous division of the fascia in Dupuytren's contraction. This required many operations and laborious treatment with special splints applied to the fingers. Mr. William Adams's name is to be associated with the subcutaneous method, which is still employed by some surgeons; in slight cases it may meet with success. Following Lord Lister's great discoveries, the open excision of the fascial bands naturally came into vogue, and must of necessity continue to form a chief part in the treatment. Such attempts to cure the deforming contraction as the use of X rays, fibrolysin, ionisation, short-circuiting intestine for imaginary stasis, &c., need not be described here; they are quite useless.

As regards the open excision of the fascia we may admit that in early cases it attains a good result. But in long-standing ones where the contraction is very pronounced I contend that this method, however carefully performed, leaves a good deal to be desired; it is far from perfect.

1. It is impossible by it alone to straighten the bent finger; indeed, sometimes the degree of flexion remains the

same as before, and the surgeon may be driven to amputate the digit.

2. Following the operation a prolonged and irksome splint-treatment is always advocated, and in the subjects of Dupuytren's contraction stiffening of the digits and hand is very apt to occur as a result. If any splint be employed it should only be for a few days whilst the wound is healing, and it is best to remove it daily so that the digits concerned should be gently bent.

Let the surgeon remember that stiffness of the fingers resulting from his treatment may prove a worse evil than their original contraction. As a rule the patient only submits to operative measures when the finger is bent strongly into the palm, when the deformity has lasted a long time, and at this stage the question of consecutive changes in the ligaments of the finger-joints becomes as important as the contraction of the fascia.

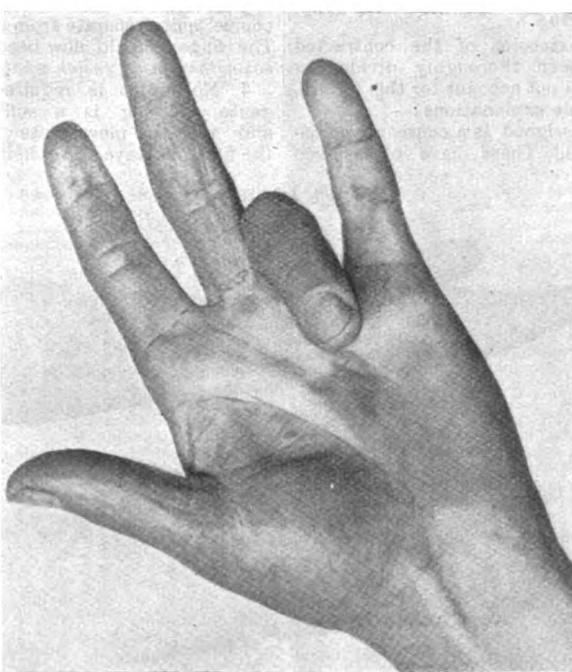

#### ANATOMY AND PATHOLOGY.

Strange to say, the current teaching as to the joint most concerned is quite wrong. To quote one of the most recent writers on the subject.

The forced flexion of the finger concerns solely the metacarpo-phalangeal joint. .... If one tries to extend the first phalanx one makes the cord project forwards which ties it to the hollow of the palm. The second phalanx is equally flexed on the first, the third is in a position intermediate between flexion and extension, but these last two segments allow of easy extension and have preserved all their freedom and integrity of passive motion.<sup>1</sup>

As will be shown directly, almost every particular dictum in this account, taken from the best French text-book, is untrue. A German writer<sup>2</sup> states more vaguely that in Dupuytren's contraction "the bending commences in the metacarpo-phalangeal joint and later involves the lower ones."

Similar views from English works could be readily quoted; in fact, the universal opinion prevails that as contraction of the palmar fascia would naturally be expected to involve flexion of the metacarpo-phalangeal joint, therefore it alone need be considered. It has not occurred to surgeons to test these views by X ray photographs. Fig. 4 is taken from an exact tracing of one

The contraction is seen to involve the first interphalangeal joint entirely. (See text.)

(made by my friend, Dr. Gilbert Scott, at the London Hospital). It shows the little finger of each hand of a man in whom Dupuytren's contraction was symmetrical and concerned only the fifth digit. The lowest interphalangeal joint (C) is in full extension, the metacarpo-phalangeal one (A) is slightly bent (about 40 degrees), whilst the joint between the first and second phalanges is bent to the utmost possible extent (a full right angle). The base of the second phalanx is seen to be pressed against the neck of the first one; no further flexion could occur. In front of each last phalanx slight bony irregularity will be noticed, and in one finger (D in the upper figure) this outgrowth of bone forms an eminence in front of the second phalangeal shaft. Such outgrowths or irregularities are common in the fingers of working men, and are to be ascribed more to hard use of the tendons than as proving a relation (often wrongly asserted) between Dupuytren's contraction and osteo-

<sup>1</sup> Maclaire on Dupuytren's Contraction, Le Dentu and Delbet Traité de Chirurgie, xxxiii., 127.

<sup>2</sup> Sultan, Spéciale Chirurgie, ii., 415.

arthritis. It will be noticed that in this typical X ray picture the actual joint surfaces are perfect.

It is somewhat difficult to explain why in Dupuytren's contraction it is the first interphalangeal joint that is the important one, though it is easy to see why the last one should escape, for the palmar fascia sends no fibres down so low as that. I may suggest that in the normal hand at rest extension is the usual position of the first and last joints, whilst at the second joint (the first interphalangeal one) flexion is habitual. Granting that the lowest slips of hypertrophied palmar fascia reach down in front of this latter joint, we may conclude that its usual position of flexion becomes readily exaggerated as Dupuytren's contraction commences and progresses.

At any rate, whatever the explanation may be, Mauclaire's description of the pathology is quite mistaken. It is the first interphalangeal joint which is most affected by the contraction, and it is this joint (so far from "preserving its freedom and integrity of movement") which in long-standing cases is found to offer an invincible obstacle to the finger being rectified after the fascia has been divided or excised.

It has, I hope, been conclusively shown that in Dupuytren's contraction the site of greatest flexion is the first interphalangeal joint, and it is a remarkable fact that the palmar fascia in its normal state is not described as reaching nearly so low as this. In the long account and numerous illustrations of the palmar fascia given by Testut<sup>3</sup> the lowest point to which the fibres are traced is the base of the first phalanx on its dorsal aspect. Practically the whole fascia ends at the level of the web. In other words, according to Testut, the human hand does not possess any fibrous bands going to the fingers which by their hypertrophy and shortening could possibly produce flexion of the first joint. Yet this is without doubt most contracted in this disease. Professors D. J. Cunningham and Merkel in their treatises on Anatomy, Poirier and Charpey in their voluminous account of the fascia, are equally silent on the subject. The last-named authors note that a few longitudinal fibres may be traced to "the level of the highest furrow across the fingers where they end in the skin." This point is at least an inch above the joint concerned. It is noteworthy that Dupuytren's observations have led anatomists to investigate and describe the palmar fascia with especial care and that the smallest fasciculi of it have been followed out.

In an excellent dissection of the palmar fascia in the Royal College of Surgeons Museum some delicate fibrous bands are shown in front of the first phalanx, chiefly attached to its sides, but even if these were hypertrophied and shortened they could not produce flexion of the second phalanx. Yet clinical experience shows there is actually a firm band of fibrous tissue running down in front of the first interphalangeal joint, which is responsible for the chief deformity and which should always be dissected out in the open operation. We must, therefore, admit that in Dupuytren's contraction the thickening does not limit itself to the normal anatomical bands, but that fresh fibrous prolongations are developed. Certainly in the palm the overgrowth of the fascia (and sometimes of the skin) becomes almost a caricature of the normal arrangement.

#### THE RISK OF AFTER-TREATMENT BY CONTINUOUS SPLINTING.

The after-treatment usually advocated in a case of Dupuytren's contraction—i.e., that following operation, whether subcutaneous or open division, is so serious and irksome that any method which lessens, or, better still, does away with it, deserves a careful trial. The following is the course of treatment after operation which is at present in vogue. A special metal splint which holds all the joints rigid from wrist down to the terminal joints of the affected fingers "must be worn night and day for the first month"; then a still longer dorsal splint to be worn again night and day, but removed two or three times daily for massage and passive movements to be practised. With this continuous splinting for ten weeks it is obvious that a working man for the whole of this time would be unable to use his hand, and at the end of it would doubtless have lost his employment. This is not all, however. For a further term of at least four months the patient should not give up the use of the splint at night! "When there is much stiffness of the joints a course of treatment by superheated air is useful in getting the part supple." One thing is certain—that if such vigorous and prolonged splinting is carried out the joints are sure to be stiffened more or less, and no hot-air baths will give back suppleness to them.

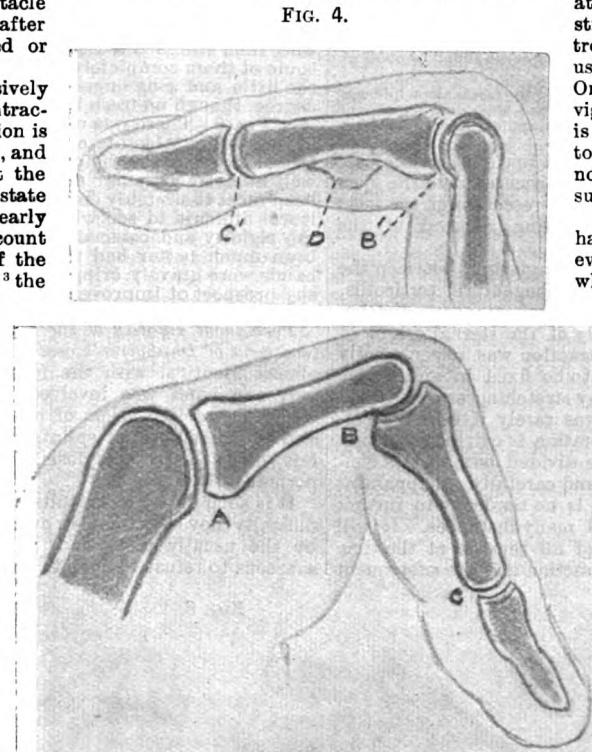

In the account from which I have quoted it is remarked that even if this irksome treatment, which puts out of use the hand for two or three months, is thoroughly carried out "no permanent cure can be looked for, as the contraction recurs within three or four years and a second operation is required." This, it is stated, happens after both the multiple division of the fascia and the V Y method.<sup>4</sup>

Now, it may fairly be asked whether even a man of leisure, one not required to earn his bread by manual labour, would care to undergo such a tedious period of crippling of the hand—for such it comes to. For a working man (and most of us have to use our hands extensively) it is positively disastrous, as I have said it generally means that some other man is found to occupy his berth by the time the patient is

allowed to give up his splint. Nor can a working man be expected to apply the splint every night for a period of six months. It may be said by the advocates of the treatment given above that the whole hand is not confined, only the fingers operated on. But a splint which fixes these and the wrist-joint does put the hand *hors de combat* so far as any working use is concerned. Let any surgeon try wearing such a splint for a week—much less for two months—and he will realise what an infliction and a disability it amounts to. I wish to bring out clearly that by the method now advocated this prolonged splint treatment is done away with; after the operation wounds have healed (a week should suffice) no splint whatever is required, the patient should be encouraged to flex and extend all the joints of all the fingers, and should certainly be back at work within a few weeks of the date of operation.

As to the risk of recurrence, my experience of the method is not long enough to allow me to be dogmatic, but my conviction is that the reliance on splints to stretch the fingers and complete the case is not only fallacious but is apt to

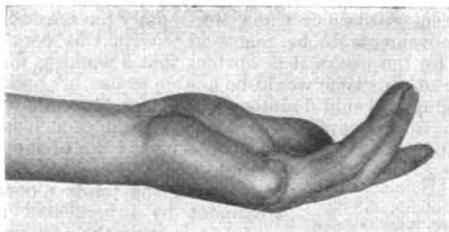

<sup>4</sup> The quotations are from Cheyne and Burghard's *Surgical Treatment*, revised by Messrs. Legg and Edmunds. Similar stringent directions as to the after-treatment will be found in other books.

Radiographs from a typical case of Dupuytren's contraction (involving both little fingers). The explanation of the lettering is in the text.

increase the formation of fibrous tissue in front of the digits, *certainly it risks stiffening of joints and adhesions of tendons to their sheaths*. And once this stiffening has been produced, as I have seen several unfortunate examples, no known treatment will effect any material improvement in it. To sum up the question—loss of suppleness in the fingers due to the surgeon's use of splints may be a greater drawback to the patient than the original contraction. In the after-treatment of a case of Dupuytren's contraction splints

FIG. 5.

Indifferent result after treatment by excision of the fascia alone followed by prolonged splinting. The little finger had been amputated, the others remained stiffened in the position shown.

should be dispensed with after the first few days, if they are used at all. This desirable end can be secured if to the open excision of the fascial bands is added resection of the head of the first phalanx with its resulting removal of the tendency to flexion of the digit.

A fair analogy is afforded by the comparison between the modern and the old treatment of "congenital" torticollis. When the surgeons were content with subcutaneous division of the sterno-mastoid (perhaps only of the sternal origin of the muscle) the tendency to contraction was never wholly removed, the patient's neck had to be fixed in an irksome apparatus, subsequent treatment by stretching exercises had to be employed, and the result was rarely if ever perfect. On the other hand, if the open operation is carried out, if not only both heads of the muscle be divided but also its contracted fascial sheath thoroughly and carefully, all apparatus may be dispensed with and there is no tendency to further contraction. Of this I have had many instances. It will probably prove that the removal of all tension at the time of operation on Dupuytren's contraction and the subsequent avoidance of splint-treatment will have equally lasting effects.

#### SOME RESULTS OF PREVAILING METHODS OF TREATMENT.

It may seem invidious to bring forward examples of failure of treatment by other surgeons, but the view is still held that all cases (mild or severe) of Dupuytren's contraction can be treated successfully by the prevailing methods—either of subcutaneous division or of open excision of the fascial bands. It is my contention that they cannot, and my wish to introduce a new and real improvement. Fig. 5 illustrates the

result in a case operated on by a first-rate surgeon a few years ago. It is clear that after open excision of the palmar fascia he found it impossible to improve the position of the little finger, which was then amputated. The fascia was then dissected away from the third and fourth digits, which were subsequently treated on a splint to further the straightening. From this splinting a good deal of stiffness has resulted and the fingers cannot be

straightened any more than is shown in the figure. They can be bent a little, especially at the metacarpo-phalangeal joints, but the grip of the hand does not include these fingers, it is poor at the best and limited to the thumb and index finger.

The next case illustrates still more forcibly my contention, *arthritis and contraction of nearly all joints of both hands following the treatment of Dupuytren's contraction of the two inner fingers*.

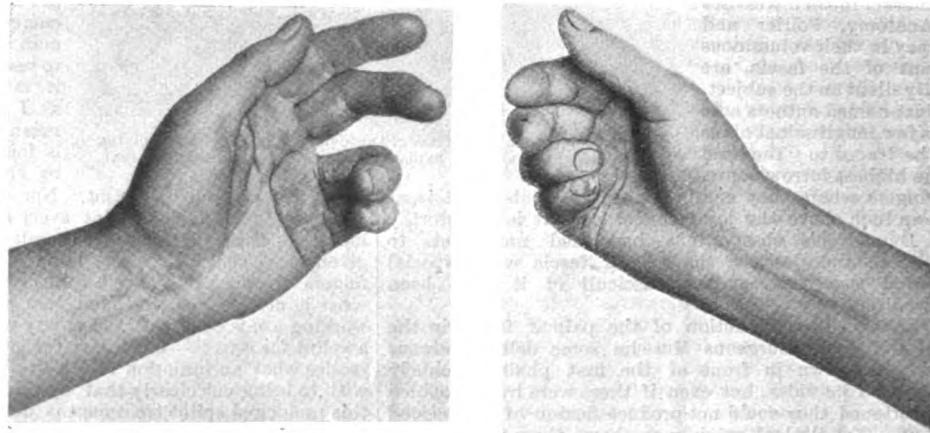

The patient, aged 57, a temperate and healthy man, who showed no evidence of either gout or rheumatic tendencies elsewhere, came under treatment for Dupuytren's contraction of the ring and little fingers of both hands of seven years' duration. The other fingers and thumbs were perfectly supple.

He had two operations performed, first on one hand and then on the other, the contracted bands being dissected out by linear anterior incision. These operations were done by different surgeons and the after-treatment carefully carried out, especially as regards making the patient wear a palmar splint at night-time. This latter procedure he kept up for 18 months, when I saw him for the first time. Both hands were then stiffened as regards all the fingers and the thumbs, some of them completely rigid and contracted. On one hand the little and ring fingers had again bent in to an extreme degree, though no fresh bands of palmar fascia could be felt. (See Fig. 6.) There was undoubtedly evidence of osteo-arthritis of various digital joints, especially of the first interphalangeal ones, and from the rigidity there must have been intra- as well as extra-articular adhesions. Massage, baths, &c., had been most thoroughly employed, though without benefit, and it was difficult to see what more could be done to improve the rigidity and osteo-arthritis. The condition would have been much better had no operation ever been done, as his hands were gravely crippled in all the digits, nor was there any prospect of improvement.

*Permanent rigidity of the whole hand left after operative treatment of Dupuytren's contraction of one finger.* This was almost identical with the former case, though fortunately only one hand was involved. The surgeon had operated on the contracted fascia of one finger; owing to too careful and prolonged use of splints not only were all the fingers left crippled by ankylosis, but the wrist-joint became permanently rigid.

It is such disastrous results as the above, coupled with the difficulty they have found in overcoming the original deformity by the usually advocated methods, that have led some surgeons to refuse to operate on Dupuytren's contraction.

FIG. 6.

Crippling of both hands from multiple osteo-arthritis, &c., due to prolonged splinting after operation (excision of palmar fascia). All the digits are rigid and bent, the deformity has recurred, and both hands are practically useless. (See text.)

#### INCISIONS USED IN DEALING WITH PALMAR FASCIA.

The examples adduced must be enough to bring home the dangers of splint treatment after the operation; a few words remain to be said about the incisions employed in dealing with the palmar fascia. The V Y method in either of its forms, whether the angular reflected flap is made of skin only or of skin and fascia together, is not a good one. It

involves too much scarring of the palm, the prolongation of the fascia to the second phalanx (which we have seen is all-important) cannot be dealt with by this method. In plastic surgery elsewhere (for example, in dealing with ectropion of the eyelids) the V Y method is a failure. I have never known it successful in Dupuytren's contraction.

Again, it is not satisfactory to remove much skin from in front of the bent fingers and to trust to skin-grafts. Mr. W. H. A. Jacobson<sup>5</sup> well pointed out their drawbacks. The wide excision of skin and fascia, followed by transplantation of a flap from the side of the chest (Paul Berger's method)<sup>6</sup> has nothing whatever to recommend it. Among other faults, it fails entirely to deal with the contraction of the first interphalangeal joint. It is strange to find this method recommended above all others in the latest French work.

Seeing that we entirely reject the wide excision of palmar skin as well as the V Y method of a shifting flap, what is the best form of incision to employ? With the proviso that all scars in the palm may prove a slight drawback and should be made as short as is consistent with the thorough dissection of the contracted bands, further that it is useless to lay down exact lines of incision for differing cases, the following points are worthy of consideration.

1. The main incision must be linear and vertical, over or closely parallel to the ridges of palmar fascia. Small transverse incisions at the front of the web may be needed, and any prolongation of the fascia in front of the first phalanx must be followed down and dissected out.

2. In the case of the middle or ring finger it is impossible to avoid placing the incision towards the mid-palm. In the case of the little finger alone the incision may be made rather to the ulnar side of the hand, where the skin is more supple and less subject to pressure.

3. In closing the wounds the finest silkworm-gut (ophthalmic) should be used. It is rarely necessary to leave any raw area to granulate up, especially if the head of the first phalanx has been excised and tension in the front of the finger thus removed.

Should a small plastic operation be required a tongue-shaped flap with its base upwards might be taken from the side of the digit concerned and shifted over so as to lie transversely. I have repeatedly used this method in cases of ectropion with good results, but in Dupuytren's contraction it can be rarely necessary. As such a flap contains the whole thickness of the skin and its blood-supply, and is fixed in place by two or three fine sutures, it is much better than the epithelial grafts advocated in the text-books.

#### ON DUPUYTREN'S LIFE AND WORKS.

Guillaume Dupuytren, the son of a poor *avocat* (or barrister-solicitor) in the small town of Pierre-Buffière, was born on Oct. 5th, 1777. He died in Paris on Feb. 5th, 1835, at the age of 57. Dupuytren was therefore a contemporary of the two great warriors Napoleon and Wellington, being eight years junior to them, and his birth almost coincided with that of the three immortal masters of Art—Beethoven, Turner, and Hokusaï. Sir Astley Cooper was his contemporary and friend, but was his senior by nine years.

There are many biographical reviews of Dupuytren in French, but nothing like a complete account of his life or works. In English there is hardly anything of value, though the New Sydenham Society gave us his "Leçons Orales" in an admirable translation. Of the French notices of Dupuytren several were written in a very critical or hostile spirit, and even as to the facts and dates of his life contradictory accounts are frequently met with.

I hope later to publish more fully a biography of the man who was certainly the most famous, if not the greatest, of all French surgeons; on the present occasion a brief notice will have to suffice.

In 1789, the first year of the French Revolution, a certain Captain Keffer, when passing through Pierre-Buffière with his regiment, was so taken with the young Dupuytren that he offered to have him educated in Paris, an offer gladly accepted by the parents. The next four years were spent in the Collège de la Marche, of which M. Keffer, the captain's brother, was the principal. Dupuytren's studies were brought to an abrupt end at the age of 16 by the closure of the Paris schools, and in 1793 he journeyed home on foot—200 miles. A few months later, his father having decided in favour of the profession of medicine, Dupuytren returned to Paris.

His student days were passed under the greatest difficulties owing to extreme poverty. His relations would not or could not help him, and in a state of complete destitution he would have gone under but for the succour of an illiterate water-carrier from Auvergne, named Jean Sebastian. This poor but saint-like man provided lodging and food for Dupuytren (who had for many weeks subsisted on bread alone), found money for necessary books and fees, and was rewarded by Dupuytren's appointment (at the age of 18) to be Prosector of Anatomy at the École de Santé. This post was paid, however poorly, and by teaching anatomy and surgery (!) the young student eked out a living. Unfortunately his benefactor died, in Dupuytren's arms, at the very time when the latter was about to pay back some of the priceless help he had received.

He had taken his degree as Doctor of Surgery before he was 20, and five years later we find him "chef des travaux anatomiques," and, what was of far more importance, second surgeon (a new appointment) at the Hôtel Dieu. Both appointments were given after public competition (Concours). M. Pelletan was the chief surgeon at the Hôtel Dieu, and it must be owned that Dupuytren proved an unpleasant colleague. It is evident from his writings that he had a low opinion of Pelletan's surgical ability, if not a strong personal animosity towards him, and in 1808 he succeeded in compelling him to resign. Thus, at the age of 30, Dupuytren stepped into the post of surgeon to the Hôtel Dieu and for the next 20 years he had sole control of the surgical wards in the only large hospital in Paris. In this unique position, with the care of some 500 beds, he accomplished an amount of strenuous work which can rarely, if ever, have been surpassed. He did everything—operated on all cases alike in general surgery, ophthalmic work, gynaecology, and other special branches. He lectured to classes which sometimes numbered 500, he conducted an out-patient clinic, made surgical post-mortems, visited the wards, and performed the dressings himself. His hospital visit began every day at 5 A.M., summer and winter he rarely missed a day; he left the Hôtel Dieu only at 1 P.M., and habitually made an evening round of the wards. With all this prodigious hospital work he carried on a private practice which enabled him to save the great fortune of £150,000. His repute as a consultant, an operator, and a teacher was European; his only rival in these respects was Sir Astley Cooper.

#### *Some Events in Dupuytren's Life.*

Dupuytren must have witnessed the stirring events of the Revolution in Paris. Marat lived and was assassinated by Charlotte Corday in the Rue de l'École de Médecine; Marat's club—the scene of his and Danton's frenzied orations—stood at the end of this street, and the hall itself became ultimately the Dupuytren Museum. This is the only part of the old convent of the Cordeliers which has survived to the present time.

When the allied troops were taking Paris in 1814, Dupuytren showed personal bravery at the head of an impromptu ambulance party which he organised from his internes of the Hôtel Dieu and led out to La Villette.

During the occupation of Paris Dupuytren, then and until his death residing in a house on the right bank of the Seine opposite to the Louvre, had quartered on him a young Russian ensign named Kazakov, who has left an account of his host which is full of interest. This Russian officer survived until 1883, his narrative only came to light a few years ago, and I discovered it by accident. Kazakov describes Dupuytren as having been a kindly but tyrannical host, living in simple style (although he then enjoyed a large practice and income) with his wife and only daughter. It may be noted that Madame Dupuytren seems to have left him later—there was some scandal. It was his ambition to make his daughter a great heiress, and with the exception of a moderate legacy to found a Chair of Pathological Anatomy, all Dupuytren's wealth passed at his death to her.

Alike under Napoleon, Louis XVIII., Charles X., and Louis Philippe, Dupuytren's star never failed him. His being a freethinker in religion did not hinder his Court appointment as surgeon to bigoted Catholic monarchs. When the King's brother, the Duc de Berri, was assassinated at the Opera, Dupuytren was called to attend him; he subsequently published an often-quoted account of the death scene. This was written partly to defend himself from hostile critics and professional enemies, who never failed Dupuytren throughout his whole career. The Duc de Berri

<sup>5</sup> Jacobson's Operations of Surgery, 1907 edition, i., 30.  
<sup>6</sup> Paul Berger, Acad. de Méd., April 20th, 1892.

had been stabbed in the chest, and for some reason Dupuytren thought it right to enlarge the wound. The dramatic scene at the Opera, when the Duke's wife met and acknowledged for the first time two illegitimate daughters of her husband, has been pictured and engraved. Amongst the crowd grouped round the dying Prince Dupuytren's portrait may be recognised.

This is the only one of all the State episodes in Dupuytren's experience of which he has left a record. He was, in fact, through life absorbed in his professional work; he had no other interests, no politics, no religion, and no friend except his daughter. A stern, melancholy, ambitious, and bitter man, it is difficult to idealise Dupuytren except as a martyr to his work. When urged to have assistance at his hospital, or to take some holiday or rest, his reply would be, "There is no rest but the grave." An attack of partial hemiplegia during the delivery of a clinical lecture warned him of the inevitable breakdown which must follow such perpetual toil as his; two assistant surgeons were practically forced upon him. A journey to Italy for the benefit of his health, the first time Dupuytren ever left France, was of no avail. He returned to Paris and resumed his arduous work. A chill contracted during his hospital work resulted in pleuritic effusion, of which he died.

It is a mistake to assume that the Dupuytren Museum was founded or endowed by him: it owes nothing but its name and a few specimens to him. In this respect our Hunterian Museum, which was in being long before Paris had any adequate pathological collection, is a marked contrast, as John Hunter gave everything to it. In size and importance our museum far surpasses its French rival: there is really no comparison to be made between them.

#### *Dupuytren's Surgical Work.*

Dupuytren's surgical teaching and experience are contained in the "Leçons Orales" and the second edition of Sabatier's "Operative Surgery." In both cases his pupils, aided and directed by Dupuytren, reported his lectures and arranged his observations. The "Leçons Orales" deals with a great number of subjects in a somewhat disjointed manner, the other work is more systematic. Both contain copious narratives of cases and pathological records spread over several thousands of pages.

It is strange that Dupuytren neglected the aid of all illustrations, whilst Sir Astley Cooper employed them so freely and so well that it is still a pleasure to consult his works. Had Dupuytren followed his rival's example his works would not have fallen into such oblivion. Dupuytren lectured to immense audiences, but there is little reason to consider him an eloquent orator, and his writings lack the attraction and the style of Sir James Paget or Sir Frederick Treves. In spite of his unique position, in sole control during a generation of the one great surgical clinic in Paris, it can hardly be claimed for Dupuytren that he made great discoveries in surgery. Nevertheless, we owe to him many valuable observations and real advances in our science. He first demonstrated the nature of yellow elastic and erectile tissues, and he proved on animals that excision of the spleen could be safely carried out.

He showed that iliac abscess on the right side was frequently due to perforation of the vermiciform appendix; that chronic enlargement of the testis was often caused by syphilis and was curable by mercury given internally. Dupuytren's pill for syphilis, containing bichloride of mercury, is still advised in France as an addition to the treatment by galyl. He wrote copiously on fractures of the long bones, and greatly improved their treatment, especially those of the femoral neck and lower end of the fibula. His treatment of artificial anus survived until recent years. He was the first surgeon to excise a carcinomatous cervix uteri and the first to describe congenital dislocation of the hip. Dupuytren was specially interested in the treatment of both lacrymal fistula and cataract; the former he improved, but he adopted the operation of "couching" with his special needle as the routine operation for cataract. In this he was certainly wrong, and sinned against the light of his time in more than one sense.

With regard to the surgery of the blood-vessels Dupuytren records many interesting and bold operations, following in part those of Abernethy and Cooper. He devised a whole series of surgical instruments, and did invaluable service in reforming the treatment of urethral stricture by introducing the gradual dilatation by flexible bougies.

Of all his work in surgery, perhaps the most original was that on the contraction of the palmar fascia, which has immortalised his name. Whether Sir Astley Cooper first suggested the right explanation of this condition (as asserted by one French writer) or not is quite immaterial. But it may remind us of the fact that Dupuytren, though he never visited England, was a friend of Cooper's, and that his writings are full of references to his works and those of other English surgeons. He had a special admiration for Sir William Lawrence's writings, and to English visitors in Paris he opened his mind more fully than to any others.

#### TWO POINTS CONCERNING FRENCH HOSPITALS.

The Duke of Wellington repeatedly affirmed (about the year 1840) in words that deserve to be recalled: "It is an old and very strong conviction of mine that in matters of peace we can do nothing except in cooperation with France." In medicine and surgery the two nations have learnt much from each other; a closer understanding must result in further gain. I will allude to two points only brought out by the study of Dupuytren's life and time.

The first is the system of election to hospital appointments. From the period of the Revolution to the present one the French have elected their hospital surgeons by public competitive examination—the Concours. This examination is, exactly like that for the Final Fellowship, held in public. In England until quite recently the selection at some hospitals was made through canvassing the votes of a heterogeneous mass of governors! It would need the caustic pen of a Charles Dickens to describe the iniquity, the expense, the absurdity of such a system. Fortunately it is now extinct, or very nearly so. The present method of selection varies somewhat at different hospitals. It has many defects, but the best candidates are elected by it in a moderate proportion of cases. Could we improve matters by adopting the Concours? Probably we should, but the change is not likely to be made.

The other point is of far greater importance. In France for over a hundred years the hospitals have derived much of their income from a tax (3 to 10 per cent.) on the gross receipts of all theatres, music-halls, and other places of entertainment. The year before the war, in Paris the income from this source was no less than £250,000. In London a similar tax would produce an annual revenue of at least £500,000. How long will it take us to follow the admirable example set in this respect by the French? The flow of private benevolence need not be checked by it, nor endowments, nor help given by Government to Universities or medical colleges. We want the money badly. The hospitals, apart from their maintenance, need more convalescent homes; they ought to be enabled to pay their nursing staffs in a more adequate manner. In Paris all who work in the hospitals or who teach medical students, from the internes to the professors, receive some salary; many of the teachers are well paid. In London medical education, research work, and clinical teaching are alike hampered and starved through want of funds and pecuniary encouragement. The teachers of science, such as those of anatomy, physiology, bacteriology, &c., may perhaps earn a living, but never a sufficient recompense. The clinical teachers, who train our students in the most important part of their career, with rare exceptions receive no pay at all. Again, in Paris every year many valuable money prizes are given for original research and essays in medicine and surgery. In London, the richest capital in the world, there is only one such reward annually given for original work on a surgical subject, the Jacksonian prize of the College of Surgeons. Its net value is £13 or £14. The drawings alone which accompany the essay may well have cost the successful competitor £100.

Surely we have much yet to learn from France.

#### "CONCLUSION."

In the first part of this lecture I trust that a real addition to our knowledge of the pathology and treatment of Dupuytren's contraction has been established. To devise and introduce some improvement, to render more easy and effectual our treatment of a disabling deformity, is in itself a source of personal pleasure. That pleasure is much enhanced by the knowledge that a tribute has at the same time been paid from this theatre to the memory of the distinguished French surgeon whose life and works we have been considering, and to the great nation with whom we are henceforth indissolubly allied.

## ABSTRACT OF

## An Address

ON THE

HUNTERIAN TRADITION IN CARDIAC  
RESEARCH.*Being the Eighty-ninth Annual Oration delivered before the  
Hunterian Society on Feb. 14th, 1917.*By W. LANGDON BROWN, M.A., M.D.CANTAB.,  
F.R.C.P. LOND.,ASSISTANT PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL AND  
PHYSICIAN TO THE METROPOLITAN HOSPITAL;  
CAPTAIN, R.A.M.C. (T.F.).

[AFTER giving a sketch of John Hunter's personal relations with his colleagues at St. Bartholomew's Hospital, the lecturer continued:—]

*Hunter's Conception of the Heart and its Modern  
Development.*

I must turn now from the association of John Hunter with some of the eminent men of the past to consider the influence of his methods in the present and their promise for the future. And my reasons for selecting cardiac research from which to illustrate this are twofold. It is a branch of medicine which in the last few years has shown active progress, and that progress has been achieved by exact observation and the comparative method. Everyone realises what an essential part experiment played in Hunter's work, but less has been said of the liberal use he made of comparative anatomy and physiology. Yet the arrangement of his museum shows that this was really the dominant idea with him. And comparative anatomy and physiology lie at the root of the advances in cardiac research.

I regard as Hunter's two great contributions to cardiology the classification of animals based on the arrangement of the chambers of the heart and the generalisation that the situation of the heart depends on the situation of the organs of respiration, which it always follows. The latter point is of great value, but not germane to our present topic. It is admirably illustrated by the descent of the heart from the neck in the gill-breathing embryo into the thorax of the lung-breathing adult, a descent which explains the curious course of the recurrent laryngeal nerves. As to his classification of animals according to the arrangement of the heart, Sir Richard Owen considered it superior to that of Linnaeus, and spoke thus of Hunter as a comparative anatomist, "He merits a higher and altogether different station than has been awarded him by Cuvier. It appears to me that he marks a new epoch in its history." This is praise indeed. Hunter's conception of the heart was that of a tube which, as we ascend the animal scale, becomes increasingly complex in the arrangement of its chambers, the insects having but one (monocilia), the fishes two (dicoilia), the amphibia three (tricilia), and the birds and mammals four (tetracilia).

It is now more than 25 years since at Cambridge I came under the influence and teaching of Gaskell, surely one of the most original minds that ever adorned British physiology. On the experimental and comparative side his work on the heart and sympathetic nervous system laid the foundation for all our recent advances. And while he was working in the laboratory, a busy practitioner in a Northern town was carefully observing patients and recording year after year the vagaries of their pulses and the reaction of their hearts to the stress and strain of life. I mean, of course, Sir James Mackenzie. Starting from two entirely different standpoints, the observations of these two men converged at last and led to a reconstruction of our ideas of cardiac pathology, which is full of promise for the future. Without recounting the steps by which the knowledge was obtained, I may summarise the development of the Hunterian conception of the heart as follows.

If we look at the vascular area of a chick early on the second day of incubation we see the heart is then a simple tube, slightly bent on itself. Pulsations are passing slowly from the venous to the arterial end, and this rhythm begins long before there is any differentiation into muscular and nervous elements. Here is the primitive cardiac tube in actual existence, and not as a mere concept. By the end of

that day the heart has become S-shaped, the form found in the fish throughout life, and rudiments of the auricular appendix have appeared. The next day the curvature of the tube has increased, and the demarcation of its several cavities can be made out. In fact, the embryo rapidly repeats events in the evolution of the heart which we believe originally occupied many ages. In the process of evolution the primitive tissue became reduced in amount but more concentrated in position, while more highly differentiated muscle developed in the lateral expansions of the tube to increase the content of the heart. This muscle was specialised for rapidity of contraction. Incidentally I may point out that it is a necessary consequence of a lateral expansion of a tube that it should contract more rapidly than the central portions if there is to be a coördinated wave at all.

Gaskell concluded that the heart-beat normally began at the sinus venosus in a heart such as the tortoise's because the muscle here was of a more embryonic character, while the ventricular muscle was more highly differentiated. But by warming the ventricular end and cooling the sinus he was able to produce a series of reversed beats. He showed that the normal wave of contraction would pass by any channel as long as a sufficiently wide bridge of muscle were left for it; the contraction was a property of the cardiac muscle and not of any ganglion cells. If the bridge was made too narrow by cutting too deeply into the muscles every wave could not pass, though perhaps alternate ones would; he had produced a partial heart-block. An adequate strand of conducting tissue is, therefore, essential to the due propagation of the wave of contraction along the cardiac tube. Such a strand was found to exist in the mammalian heart by Stanley Kent in 1893. In our characteristic British way we ignored this discovery until it was rediscovered by a German, His; then we accepted it, and the strand is now known as the auriculo-ventricular bundle. It is composed of fine, pale, branching fibres, which in some respects resemble embryonic muscle fibres. But if such fibres are the conducting strand along which the wave passes, we should expect to find similar fibres at the junction of the great veins with the heart, since this is where the wave starts, and Keith and Flack found them there, in close connexion with the vagus and sympathetic nerves. They called this the sino-auricular node. Here the dominating rhythm of the heart normally arises, and here it may be readily modified by extrinsic nerves. Between the sino-auricular node and the auriculo-ventricular bundle there appears to be none of the primitive cardiac tube left. This extreme reduction of the primitive tissue is typical of the mammalian heart, and with this reduction the heart has become less automatic in its action and more in subjection to the central nervous system.

Like the chick's heart on the second day, the remains of the primitive cardiac tube appear to be endowed with the properties of both muscle and nerve. In some lower types, such as *Limulus*, the king-crab, the nervous and muscular elements are anatomically separate. In the mammal we can effect this separation by chloral, which poisons the nervous elements, so that the heart muscle will now behave like ordinary striped muscle.

Just as Gaskell was able to make the tortoise's heart start beating at an abnormal spot, so we find that extra beats may start in the human heart from an abnormal position. Just as he was able to produce heart-block by interference with the conducting bridge, so we may see heart-block produced in man by disease of the auriculo-ventricular bundle. The beats may also be initiated by the irritation of extrinsic nerves, acting on the sino-auricular node. It is the special value of Mackenzie's work that it has enabled us to classify the principal forms of irregular heart met with clinically in terms of disturbance of the primitive cardiac tube.

I propose now briefly to consider some of the recent additions to our knowledge under the three heads of the irregular heart, the dilated heart, and the irritable heart.

*The Irregular Heart.*

Five types of irregularity are now recognised of very different significance. It is important to realise that they are not all of serious portent. I shall place them in the order of increasing gravity.

1. *Sinus irregularity.*—This Mackenzie calls the youthful type of irregularity, and it is compatible with a perfectly healthy heart. The rhythm is initiated at the normal place, at the sino-auricular "pacemaker," but not at the normal

time. One the wave of contraction is started, it is propagated quite normally. The duration of systole remains constant, but the diastolic intervals vary. As the pulse quickens the diastolic intervals are encroached upon, so that this type of irregularity disappears during fever or exertion. It is due to vagal irritation, as is shown by the way it may be induced by swallowing or by hurried respirations—two acts which stimulate the sensory branches of the vagus. Sinus irregularity can be recognised by the fact that though the pulse-rate is varying, usually with respiration, the beats are equal in strength, while on auscultation the interval between the first and second sounds is constant. It does not cause any inconvenience, and its recognition is important simply that undue significance may not be attached to it.

**2. Extrasystoles.**—When a stimulus is initiated at some other part of the heart than the sino-auricular node a premature contraction will occur, and as the heart has not had time to accumulate enough contractile material, this beat will be smaller than normal, and, for a similar reason, it will be followed by a longer pause. This disturbance of rhythm constitutes the extrasystole, and usually involves the ventricle alone, though it may occasionally implicate the auricle. The patient is conscious of the long pause and of the thud which follows it, and it can be detected without instrumental aid by the two beats in rapid succession followed by the pause. The electrocardiogram will show that the extra beat has started from some situation other than the primitive cardiac tube, and for that reason it has been called an "ectopic beat." Mackenzie calls it the adult type of irregularity, and says that hardly anyone over 60 fails to show it. It is often induced by gastric disturbances and by drugs. In itself it does not give any cause for anxiety. Attention to the digestion, and moderation in the use of tea and tobacco will diminish its occurrence, or, at any rate, diminish the patient's consciousness of it, which is all that is necessary. Paroxysmal tachycardia is apparently due to auricular extrasystoles. Transitional between this and the next type of irregularity to be described is "auricular flutter," in which the auricle may maintain a rate of more than 300 a minute. But too little is known of this rare type to make its further discussion profitable here.

**3. Auricular fibrillation.**—The explanation of this type of irregularity we owe to Thomas Lewis. It is seen in the later stages of mitral stenosis. The typical crescendo presystolic murmur may suddenly vanish and be replaced by a diastolic rumble, diminuendo in character. At the same time the pulse will become highly irregular, and usually very frequent. The veins in the neck become distended, and the patient becomes extremely distressed with shortness of breath and cyanosis. The electrocardiogram shows that the proper auricular contraction is replaced by incessant fibrillary tremors. Mitral stenosis leads to more and more strain upon the left auricle because of the difficulty it offers to its emptying its load into the left ventricle. For a time this is met by hypertrophy of the auricle, but a stage is reached when the auricle becomes so overloaded that it can no longer contract properly and only fibrillary tremors can take place. The presystolic murmur must vanish since it is produced by auricular contraction; the diastolic murmur is due to passive pouring of blood into the ventricle during diastole. As this flow of blood will diminish as the ventricle fills, the diastolic rumble produced will be diminuendo in character. The ventricular output suffers in two ways. Firstly, the auriculo-ventricular bundle is stimulated in a most irregular manner by the fibrillations of the auricle, and its contractions will be rapid because of the number of stimuli reaching it. Secondly, the output of the ventricle will be interfered with because the ventricle now lacks one of the most potent factors in the production of its systole—namely, the sudden squirting of blood into it by the short, sharp auricular contraction. As we shall see later, this stretching of the ventricular muscle by driving blood from the auricle into the ventricle is a powerful stimulus to adequate ventricular contraction. Thus the ventricle is now urged to rapid and ineffective contractions, placing the heart at a serious mechanical disadvantage, which sooner or later leads to its breakdown. It is, then, not the primitive cardiac tube that is at fault, but the thin sheet of more differentiated muscle which lies between the two remaining portions of this tube. This is the form of irregularity for which digitalis is particularly appropriate, for not only has

it a tonic action on the distended auricular muscle, but it also lowers the conductivity of the auriculo-ventricular bundle, enabling it to ignore a large number of the ineffective stimuli reaching it from the fibrillating auricle. It is clear that auricular fibrillation is a more serious form of irregularity than those we have previously considered. It connotes a structural alteration in the heart, which plays an important part in its ultimate breakdown.

**4. Heart-block.**—This condition has been known since the middle of last century as Stokes-Adams disease, but its significance and the method of its production have only been appreciated during the last decade. The characteristic features are the infrequent ventricular contractions, while the auricular contractions remain normal, and the attacks of vertigo, syncope, and epileptiform convulsions. Various anatomical lesions have been found, but the factor common to them all is damage to the auriculo-ventricular bundle, so that the passage of the wave from auricle to ventricle is interfered with. It is the clinical equivalent of the heart-block produced by Gaskell in the tortoise's heart by cutting the auricular muscle until the bridge is too narrow for all the waves starting in the auricle to be propagated into the ventricle. Perhaps two out of three waves may pass or only alternate ones. The block may become complete, so that the ventricle is dependent on its own rhythmical power for any contractions at all. Sometimes the block is caused by the toxins of disease such as rheumatism, sometimes by drugs such as digitalis, where conductivity is impaired. But more usually there is a fibrosis of the bundle or a gumma pressing on it. So that the condition is serious and tends to get progressively worse in spite of treatment. It is therefore a serious form of irregularity, since it is due to interference with the primitive cardiac tube at its narrowest, and therefore its most vulnerable, point. The syncope and convulsions are the direct result of the cerebral anaemia caused by the slow ventricular beats. When the pulse-rate falls below 30 in the minute there can hardly be an adequate supply of blood reaching the brain.

**5. The alternating pulse.**—Here the irregularity is not one of time but of force. There is a regular succession of small and large beats. It is due to a failure of contractility, and the probable explanation is that with the smaller beats not all the fibres contract. This means that some of the fibres are so exhausted that they only beat half as frequently as the rest of the heart. The condition usually occurs in elderly people with high pressure, and it may only be brought out by exertion. There must be a great impairment of the reserve force of the heart before it comes on, and according to Davenport Windle the importance of recognising this altered rhythm is that it is a danger signal which appears before the symptoms of heart failure are manifest. Either dropsy or angina is imminent, and in none of Windle's cases was life prolonged more than 17 months after alternation of the pulse had been observed.

In the briefest possible manner I have described the cardinal features of the recognised types of irregularity, some of which may coexist, producing most confusing conditions. It is sufficient for my purpose if I have made clear the relations of these irregularities to the primitive cardiac tube. In sinus irregularity the tube is healthy, but is stimulated irregularly by the vagus; in extrasystoles there is some irritable focus outside the remains of the tube; in auricular fibrillation the more differentiated muscle between the two portions of the primitive tube fails to act properly; in heart-block there is failure of conductivity through the narrowest part of the tube, while in the alternating pulse there is failure of contractility in the specialised lateral expansions of the tube. Stated in this order we have a series passing from a harmless irregularity to one which is inconsistent with life for much more than a year.

#### *The Dilated Heart.*

Recent work has thrown important light on the nature of cardiac dilatation. For some years we have known that the heart is very tolerant of interference with the systolic output, while very intolerant of interference with its diastolic filling. Thus, if a ligature be placed around the aorta of an animal and very slowly tightened, the lumen may be reduced to one-third of its normal calibre before the output of blood from the heart is diminished. On the other hand, if an aneurysm bursts into the pericardial sac a man may die suddenly although the sac contains only 10-12 oz. of blood.

No one dies from so small a loss of blood ; it is the interference with the diastolic filling that stops the heart. Similarly when people are crushed to death in a crowd they die from syncope and not from asphyxia. The fixation of the chest interferes with the return of the blood from the great veins, diastolic filling is interfered with and the heart stops. In 1908 I suggested that this interference was so deadly because it deprived the heart walls of that tension which is so powerful a stimulus to contraction. The recent work has confirmed this suggestion and amplified it in a striking manner.

We owe to A. V. Hill the conclusive demonstration that the energy developed by a muscle is directly proportional to its previous stretching. Starling and his school applied this generalisation to cardiac muscle, and showed that if the heart were given more work to do, for instance, by a rise of peripheral resistance, it would dilate until the diastolic stretching thus produced developed sufficient energy to enable the heart to do the increased work. So that dilatation in its inception is a compensatory measure. This accounts for that transitory dilatation which is often observed but has hitherto been unexplained. I have seen a patient's apex beat move an inch outwards in the course of a minute or so, and then return to its normal position ; this has usually been in a weakly person soon after undertaking some slight exertion. The enfeebled heart required this extra stretching to develop sufficient energy. But if the maximum elongation that can be obtained is not enough to develop the required energy the heart must remain dilated. This is only likely to occur if the muscular nutrition is impaired. If the myocardium is diseased its contractility is diminished and the temporary physiological dilatation passes into a permanent pathological dilatation. Now we can understand why interference with the diastolic filling is so deadly ; it prevents that stretching of the muscle which is so essential to the development of its energy. A new light is thrown on the mechanism of the filling of the auricles, the filling and the emptying of the ventricles. If the auricle is not contracting with sufficient energy a rise of venous pressure will enable the blood entering the heart to stretch the auricle more thoroughly and thus to stimulate it to increased contraction. We speak of this rise of venous pressure as a "back pressure," as if it were a consequence of failing heart, but we have not realised that it is developed as an attempt to combat that failure. This rise of venous pressure has its drawbacks. Venous pressure tells directly on the thin-walled capillaries, unlike arterial pressure, which is shut off from the capillaries by the constriction of the arterioles. A rise of pressure in these thin-walled capillaries allows transudation of fluid to occur into the surrounding tissues ; hence dropsy, albuminuria, and congested liver. Saline aperients help to restore compensation by depleting these overloaded capillaries while permitting the rise of venous pressure to exert its stimulating effect on the heart.

In the same way the auricular contraction is made as short as possible. For seven-eighths of the cardiac cycle the auricle is resting, or rather it is being stretched by the blood pouring into it from the veins. This enables it, in spite of the relative thinness of its musculature, to develop enough energy to squirt blood forcibly during the remaining one-eighth of the cycle into the ventricle. This sudden distension of the ventricle acts as a powerful stimulus, and what the loss of this stimulus means when fibrillation of the auricles occurs is seen in the consequent profound disturbance of the ventricular output.

We can also understand now why the blood pressure often rises when the heart is failing. It is sometimes a surprise to find a blood pressure of 200 mm. or even more when the heart is beating feebly and fast. It has often been assumed that the heart is failing behind the high pressure, but really the pressure is rising because the heart is failing. If the output of the ventricle is diminished the arterioles constrict in order to diminish the size of the vascular bed to be filled. But this in itself would only raise a falling blood pressure back to normal. The subsequent rise is in order to stretch the ventricular muscle, and thus to stimulate it to renewed effort. When a failing heart is accompanied by a low pressure, as it is in acute toxæmic conditions, it is because the vaso-motor system also is poisoned and cannot respond to the demands of the medulla. Death is then imminent.

This rise of arterial pressure has another advantage, as I pointed out some years ago, and as has now been experi-

mentally confirmed by Starling. The coronary arteries have no vaso-constrictor nerves. A rise of arterial pressure, therefore, drives more blood into the coronary arteries, and thereby increases the blood-supply to the heart muscle at the moment when more work is demanded of it.

The effect of a cardiac tonic is twofold ; by slowing the heart it allows of its proper filling, and therefore of its adequate stretching, but it also enables the muscle to contract with less initial stretching, with the attendant risks of over-stretching. This avoids the need of a rise of venous pressure with its accompanying drawbacks. One is impressed afresh by this new work with the extraordinary adaptation of the heart to the mechanical problems it has to face.

#### *The Irritable Heart.*

The final topic with which I wish to deal, and that quite briefly, is the irritable heart of soldiers, with which we have become so familiar of late.

A soldier may begin to find himself short of breath on any exertion, suffering from precordial pain and palpitations. He is easily exhausted and has to fall out on a march. If he lies down he soon feels all right, except perhaps for some indigestion, even when kept at rest in bed. On getting up again he feels dizzy and faint. He looks depressed ; his face is pinched and drawn. Vasomotor instability is proclaimed by the cold and rather blue extremities, which may quickly become cold and clammy. There may be tremors of the hands. He is labelled D.A.H. (disordered action of the heart) and consequently takes a gloomy view of his future, which in itself militates against his recovery. Examination of the heart does not reveal anything definite ; there is no enlargement, but there may be various murmurs, which tend to pass away with rest. Many of the murmurs I should formerly have unhesitatingly pronounced to be organic, but the way in which they pass away and reappear shows that they cannot be so. The pulse is always too fast in the upright position and may remain too rapid even when in bed. But there are no signs of failing compensation.

The condition is an intractable one. The patient accepts the diagnosis as evidence that he has definite heart disease. Parkinson found that of 39 cases he sent home only 4 had returned to duty feeling quite well, at the end of an average period of seven months (minimum 4, maximum 14 months) ; 22 of them were no better or were still in hospital. And this accords with the experience of most of us.

This form of the disease has been commoner than the definite attacks of paroxysmal tachycardia, which had often been noticed in young recruits. The condition has long been recognised, but cannot be said to have been fully explained even yet. It is prevalent among the enemy. Goldscheider says : "The war has brought into unflattering prominence the ignorance of the medical profession of a group of symptoms with which a very large proportion of the German Army have been invalidated." In 1864 it was referred to the type of accoutrements worn, in 1876 to the "setting-up drill." Both of these have been abandoned, but the disease remains. Three other explanations have been offered more recently : that it is due to a poisoned heart, that it is purely neurasthenic, and that it is due to some perversion of the internal secretions.

Sir James Mackenzie states that in his opinion 90 per cent. are not primarily heart cases, and that the principles of treatment are widely different from those for heart failure. He considers they are generally due to the effect of strain during the time that the heart is poisoned by some intercurrent infection. If this is so, it is curious that the signs and symptoms do not approximate to those of myocardial failure, which may be induced under similar conditions. But there is support to the theory in the frequency with which gastro-intestinal disturbances have preceded the heart symptoms. Da Costa noticed in the American Civil War that diarrhoea was a common precursor. This accords with my experience in the South African War. In this war we have had large numbers returned from Salonica who began to suffer with their hearts in this way after malaria, and various other infections have also been held responsible. I have not noticed a liability to irritable heart after epidemic nephritis, but this is probably due to the prolonged rest in hospital which that disease entails. Earlier in the war instances occurred where soldiers had deliberately upset their hearts by eating cordite, but this has apparently been checked by disciplinary measures.

Tobacco may be a factor in some cases, but non-smokers have suffered, and I have seen its prohibition fail to produce any improvement.

The second view is that the condition is a purely nervous one. Some years ago I was accustomed to point out, chiefly as the result of my experience in the South African War, that whereas traumatic neurasthenia was common in civil life—for instance, after a railway accident—it was comparatively rare in war. No one would venture to make such a statement to-day, for our experience in this war has singularly falsified it. Prolonged strain and high explosives have altered all that, and "shell shock" has passed into ordinary parlance. Many such cases show cardiac symptoms exactly like those of soldier's heart.

The strain of warfare may cause a breakdown in the weakest spot, which may be the vascular system. Rudolf believes that the majority of the patients have shown vaso-motor instability for years. That the sufferers from soldier's heart are neurasthenic I am convinced, but I am not convinced that the cardiac condition is due to neurasthenia. I have known some of these men before the war, and they certainly were not neurasthenic then. To refer it all to the nervous system without further explanation may be a mere cloak for ignorance, and does not tend to the satisfactory treatment of men who may be suffering from a physical incapacity, the intangible nature of which in itself increases the liability to neurasthenia.

The nervous theory is not incompatible with the internal secretory theory. Both the suprarenals and the thyroid have been held responsible. Adrenalin is one of the defensive mechanisms of the body. It is the hormone to the sympathetic nervous system, and many different stimuli lead to hurrying up of this secretion into the circulation to assist in rapid sympathetic response. But with frequent repetition of the stimuli exhaustion of the secretion may be induced with consequent loss of tone of the whole sympathetic nervous system. Previous infective conditions would hasten the exhaustion, for we know, indeed, that some diseases, such as diphtheria, have a marked effect in diminishing the amount of chromaffin material in the suprarenals.

Other observers consider that the symptoms are due to hyperthyroidism. In support of this they point to the influence of shock and fright in inducing Graves's disease, and to the existence of tremors and tachycardia with other cardiac symptoms both in Graves's disease and in the condition I am discussing. Moreover, they claim that the thyroid is often enlarged in "soldier's heart," as, indeed, I have sometimes found to be the case, and that treatment of this gland by X rays markedly benefits the patient, of which I am not so confident. Still, the theory is one that demands consideration.

In most cases one can find no definite enlargement of the thyroid and the hypothesis of a loss of balance between the internal secretions has been advanced; the suprarenal being in defect, the thyroid in excess. It is a plausible idea, but such assertions are more easy to make than to prove. Routine examinations of the blood to determine the amount of adrenalin and of sugar in the circulation would afford a basis of more value than any speculations.

As the thyroid gland is believed to play a part in the fixation of salts in the tissues, it is interesting to learn that Thomas Lewis and his fellow-workers have found a deficiency of salts in the circulation of these patients when they are short of breath. All acids, including  $\text{CO}_2$ , stimulate the respiratory centre, but if we add  $\text{CO}_2$  to blood it only produces one-quarter of the change in reaction which occurs in a corresponding quantity of salt solution. This is because the sodium bicarbonate, the sodium acid phosphate, and the protein partly fix the acid, so that it loses its chemical freedom. They act as buffer salts, easing the shock of the reaction caused by the addition of acid or alkali. When these buffer salts are diminished any exertion produces excessive fatigue, giddiness, palpitation, and a high rate of pulse and respiration. They found that after the addition *in vitro* of sodium acid phosphate to the blood of such patients they obtained a dissociation curve more nearly approaching the normal. This suggests that an alteration in salt metabolism occurs in soldier's heart, and it is quite possible that such alteration is due to a disturbance of the balance between the internal secretions of the suprarenal and of the thyroid.

But if these speculations are to prove fruitful they must be followed by experimental observations; fortunately a number of skilled workers are engaged on the task, and it is to be hoped that the difficult problem will be solved. In the meantime it is important that the patients should not be treated as primarily cardiac and that they should be disabused of the idea that they are suffering from incurable heart disease.

[Dr. Langdon Brown closed his lecture with a brief reference to the Hunterian tradition as a living tradition in present-day military medicine.]

## SPECIFICITY IN ANTISEPTICS.

BY KENNETH TAYLOR, M.A., M.D.,

DIRECTOR OF THE LABORATORIES, ROBERT WALTON GOELET RESEARCH FUND, HÔPITAL COMPLEMENTAIRE V.R. 76, FRANCE.

AFTER two years' observation and study of several thousand cases of chronic infected wounds and their treatment, it seems to me obvious that this branch of medicine has made little progress. In spite of the numerous new or newly modified methods of treatment which have sprung up and been heralded with enthusiasm since the beginning of the war—each one claimed by its champions to be far better than any of the others—it is still impossible to say of any one method or dressing solution, "This is the best way to treat an infected wound." It is probable that this lack of success is due in part at least to the failure to consider the individual characteristics of antiseptics in relation to the types of bacteria in the wound.

This discussion is limited to the consideration of the chronic infection. The treatment of the fresh wound is a different and relatively simple problem. Here the use of antiseptics is really a prophylactic measure, an attempt to kill a small number of bacteria before they have fastened upon the wounded tissues. The bacteria occupy a relatively exposed position among already damaged cells. A single application of a strong antiseptic of the protein coagulating class may succeed in killing the bacteria without penetrating beyond the already damaged tissue which rapidly combines with it and checks its action. But this method is not applicable to wounds in which repair has already begun. Here there is no surface layer of dead cells to protect the living from the antiseptic. Consequently only weak solutions can be used, and it becomes vitally necessary to choose substances having a greater toxic action on bacteria than on human cells. Since bacteria vary widely in their structure and their biology, this substance also may be expected to vary with each species or group of bacteria. It is believed that work along more specific lines may bring about substantial progress in the antiseptic treatment of suppurating wounds. These preliminary investigations are reported for the light which they may throw on the problem.

It is the object of this paper: (1) to emphasise the need of an analytical method in the study of antiseptics; (2) to suggest that specificity in the antiseptic treatment of infected wounds is as important as specificity in the antiseptic treatment of systemic infections, such as malaria, syphilis, &c.; (3) to postulate that suppurating wounds may be treated by specific means directed against one single species or group of bacteria at a time, and that only by such a method of treatment can successful sterilisation be expected; (4) to present certain evidence that this hypothesis may be put to practical application: (a) an attempt has been made to determine the relative activity of a few antibacterial substances of varied character against different groups of bacteria by means of a study of their action upon growing cultures; (b) the results of a rather extensive observation of the bacterial flora of suppurating wounds are also presented with the view of showing certain variations in that flora under various dressing solutions.

### Requirements of Antiseptics.

The failure of antiseptics to accomplish the sterilisation of chronic suppurating wounds, which has surprised so many surgeons, has led to a widespread pessimism as to their utility. This state of mind has resulted in two divergent reactions: first, there has been a great increase in the number of antiseptics used; on the other hand, it has resulted in the development of a "physiological" school of treatment in which all antiseptics are discredited and

replaced by attempts to stimulate the normal reactions of the body against the infective process. As far as dressing solutions are concerned, the "physiological school" has limited itself to solutions of sodium chloride of varying concentrations, utilising only the physical factor of a dressing solution—viz., relative tonicity.

The difficulties in the way of success in the treatment of a chronic suppurating wound are extremely hard to overcome. The irregular structure of the wound, its pockets, the presence of foreign bodies and of fragments of tissue of various sorts which have been separated from their blood-supply make it difficult for the dressing solution to reach the foci of vegetative activity of the bacteria. For example, microscopical section of bone *esquilles*, removed from old-infected fractures in this hospital, has shown foci of bacteria within the fragments of dead bone in 80 per cent. of the cases. The methods of application are inadequate to bring a dressing solution into contact with all parts of a wound. In many cases also the bacteria are lying within the living tissue, especially between the cells and within the lymph spaces below the granulating surfaces. Here it is necessary to take into account the difficulty of the diffusion of the antiseptic through lymph channels and intercellular spaces to reach the bacteria. This diffusion must take place through a medium containing albumin; therefore the diffusion factor of the antiseptic in a menstruum of this sort is of great importance. The dressing solution must be of such a character or of such a dilution that the living cells engaged in the process of repair are not injured or repelled. It must kill or check the growth of different forms of bacteria which offer varying degrees of resistance to the antiseptic.

It is perhaps too much to ask that these multiple requirements should be fulfilled by any one substance, whether it be a saline solution or an antiseptic. It is certain that up to the present time no one solution has been discovered which has effectively combined all the properties which are demanded of a general dressing solution, nor is it likely that such a one will be discovered.

#### *Search for a General Antiseptic.*

Undoubtedly a great amount of time has been wasted in the search for an impossible combination. For many years there has been firmly fixed in the minds of laboratory workers and clinicians the idea of "general antiseptics." The term itself has been a stumbling block to progress in the treatment of wounds. It suggests that there are substances which will kill *all* low forms of vegetable life while sparing the far more delicate cells of the animal body. In other lines of medical investigation generalities and empiricism have largely given place to an analytic and specific investigation. But in the case of the treatment of infected wounds we still think and act as though any "general antiseptic" were specific treatment for "the suppurating wound." It is almost as illogical to consider the symptom of fever, no matter what its cause, as an entity and treat it with a general antipyretic as it is to treat an infected wound with a general antiseptic. Until we get rid of the term "general antiseptic," and the conception of empiric treatment which it implies, and substitute some term such as "dressing solution," which carries with it no pre-conceived ideas, we are not likely to make much progress in the specific treatment of an infected wound.

The "physiological" school falls into the same error. It limits its dressings to solutions of sodium chloride, advocating either the passive treatment with physiological saline or the active treatment with strong salt solutions. The former method is purely a negative one; the latter can hardly be termed "physiological." Its proper place is among the antiseptic methods.<sup>1</sup> Each method is applied without regard to the varied character or flora of the wound.

In the treatment of the majority of chronic infected wounds the main problem lies in destroying as far as possible the bacterial flora, consisting usually of several different groups in symbiotic or perhaps in antagonistic relationship. The different groups are sensitive in different degrees to the action of many antibacterial substances. It is possible that by the utilisation of this fact they may be combated separately by the solution to which they are most sensitive, and in this way a definite reduction of the number of organisms effected. Further work may show whether there are certain antagonistic relationships between different bacteria in a wound with which it is undesirable to interfere.

#### *Experimental Evidence.*

Dressing solutions designed to combat infection may be roughly divided into four classes: (1) bland solutions without action on proteins; (2) protein coagulators; (3) protein solvents; and (4) solutions of substances exerting on proteins a *toxic* action, which, so far as can be determined, is not primarily due to either the coagulation or solution of the protein bodies. By far the most profitable field of investigation appears to lie in this class. Here a differential action on the bacterial proteins may be expected with certain substances and specific properties utilised. An attempt has been made to investigate the bactericidal properties of a few organic acids, alkaloids, or other compounds which may be included in this group of antiseptics.

It is very difficult, with any substance, to establish the actual point of concentration which will inhibit the growth of an organism. Incomplete mixture of the medium and the antiseptic may give cause for erroneous results. Variance in the number of organisms implanted may also lead to confusion. A heavy inoculation may alter the constitution of the medium or fix a certain proportion of the antiseptic. Variations in aeration of the medium may give false results in experiments with anaerobes. The inhibition point of a particular substance varies considerably in the case of a particular organism according to the age, strain, or vegetative activity of the culture used. As far as possible it is advisable to use an actively growing young culture for all experiments with antiseptics.

The technique followed by Miss Mary Davies, who conducted the experiments in this laboratory, was as follows:—

A series of tubes was filled with equal measured amounts of a fluid medium suitable for the organism. Since the determination of the relative rather than the actual bactericidal power was desired, the simple broth media were generally used. The antiseptic to be tested was then added in decreasing quantities and the two substances thoroughly mixed in the tube. All the tubes were heavily inoculated with the same amount of an actively growing culture of the organism against which the antiseptic was being tested. They were then immediately incubated. The concentration of the antiseptic was computed in the last tube to show growth and in the first to show complete inhibition. A point midway between these two was taken as the actual concentration required to inhibit growth in the medium used.

#### *Organic Acids.*

The bactericidal effects of two groups of protein toxins were studied. The first of these groups contained what may be called the natural antiseptics—i.e., those substances often produced during the growth of an organism, an accumulation of which in the medium ultimately inhibits its vegetative activity. It is well known that the growth of most bacteria *in vitro* is self-limited. This limit is reached by a process of auto-intoxication. Among the substances acting in this manner some of the most important are the organic acids produced from the medium in which the bacteria are growing. Certain of these organic acids most commonly present in the filtrate from old cultures have therefore been tested, together with a few other organic acids, in an effort to determine the actual concentration required to check the growth of various organisms. These results are shown in Table I., which also contains the inorganic acids hydrochloric and nitric for comparison.

TABLE I.—*Approximate Concentration of Acids Required to Inhibit Growth.*

Acid.	<i>Streptococcus pyogenes.</i>	<i>Staphylococcus aureus.</i>	<i>B. pyocyaneus.</i>	<i>B. aerogenes capsulatus.</i>
Hydrochloric	0·21	0·22	0·22	0·11
Nitric ...	0·16	0·23	0·22	0·11
Acetic ...	0·31	0·29	0·08	0·11
Butyric ...	0·15	0·24	0·13	0·11
Propionic ...	0·11	0·13	0·08	0·19
Tartaric ...	0·29	0·16	0·48	0·07
Malic ...	0·21	0·16	0·12	0·04
Tannic ...	0·19	0·29	0·50	0·50

Several points appearing in this table are of interest. It may be noted that the two inorganic acids showed almost the same degree of activity in checking the growth of each organism. This similarity of action suggests that it is merely the quantity and not the quality of these acids which is of importance.

The organic acids, on the other hand, differed greatly among themselves in their effect on the growth of the various

<sup>1</sup> Mechanism of Saline Dressings, Brit. Med. Jour., Sept. 2nd, 1916.

organisms: thus, acetic acid actively inhibited the growth of the *B. pyocyanus*, was slightly less active against the gas bacillus and much less so against the cocci. Propionic acid showed a similar action in regard to the *B. pyocyanus*, was much less active against the gas bacillus, and more active against streptococcus. Butyric acid was less active against *pyocyanus*, about equally so against the gas bacillus and more active against streptococcus, though not against staphylococcus. Tartaric acid showed very little action against *pyocyanus*, was very active against the gas bacillus, but had only slight effect on streptococcus. Malic acid resembled tartaric in its action on the cocci, but was fairly active against the *B. pyocyanus* and most active of all against the gas bacillus. Tannic acid showed only a slight activity against the cocci, and appeared to have no activity against the *B. pyocyanus* and the gas bacillus.

It may be concluded, therefore, that at least among the common organic acids there is a great variation or specificity in their activity toward different organisms. Further work may show to what extent this specificity is inherent in the particular products of each bacterium's growth.

#### *Antiseptics.*

Only a small group of substances of a recognised antiseptic value was examined. It comprised carbolic acid, cresol, thymol, Dakin's solution, quinine hydrochloride, ammonium and sodium fluorides, salicylic acid and sodium chloride.

TABLE II.—Approximate Concentrations of Certain Antiseptics Required to Inhibit Growth.

Antiseptic.	Streptococcus pyogenes.	Staphylococcus aureus.	B. pyocyanus.	B. aerogenes capsulatus.
Carbolic acid	0·07	0·26	0·10	Variation 0·65 to 2·00
Cresol	0·06	0·09	0·06	0·26
Thymol	0·08	0·16	0·5+	0·26
Dakin's solution*	3·42	17·60	34·34	Variation 28·62 to 50·00
Quinine hydrochloride	0·15	0·41	0·77	Variation 0·07 to 0·19
Ammonium fluoride	0·30	0·24	0·24	0·36
Sodium fluoride	0·17	0·08	0·17	0·30
Salicylic acid	0·47+	0·28	0·47+	0·08
Sodium chloride	5·51	14·28+	14·60+	4·00

\* The figures represent percentages of the solution. Since it is a complex solution it is difficult to determine the actual bactericidal value of each constituent.

Here again great variation was found in the activity of these substances on different organisms. Carbolic and cresol proved more active against the streptococcus than against the staphylococcus, and showed very little activity against the gas bacillus. Thymol showed a fair degree of activity against the streptococcus, was less active against the staphylococcus, still less so against the gas bacillus, and showed practically no action upon *pyocyanus*. Dakin's solution showed a moderate activity against the staphylococcus, was nearly inert against the *B. pyocyanus* and the gas bacillus, but was more active against the streptococcus. Quinine showed its greatest activity against the gas bacillus, was fairly active against the streptococcus, but showed very little action upon the staphylococcus and still less upon the *B. pyocyanus*. Sodium fluoride was more active than ammonium fluoride throughout. Both showed themselves active against the gas bacillus, but less effective against the other three organisms. Salicylic acid showed very little activity against streptococcus, *pyocyanus*, or staphylococcus, but was fairly active against the gas bacillus. The concentration of sodium chloride required to inhibit the growth of these four organisms also varied considerably. About 4 per cent. was required to prevent the growth of the gas bacillus, a slightly higher concentration to inhibit streptococcus, and 14 per cent. failed to inhibit the growth of the other two organisms.

Here again is plainly manifested the great variation in the activity of some of our "general antiseptics" toward the common bacteria of infected wounds. *Bactericidal values are relatively specific and not general.*

#### *Clinical Evidence.*

In order to study the effects of some of these dressing solutions on the flora of chronic suppurating wounds a series of 165 cases was divided into approximately equal numbers, and each group treated with one solution for a period of five weeks. Practically all these cases fell into the class

of chronic infection. Most were complicated with bone necrosis. The first examination was made, on an average, about two weeks after injury. The wounds were examined by Dr. B. H. Buxton of this laboratory at intervals of about seven days, and the aerobic and anaerobic flora recorded. The bacteria were classified by group only, notes being kept of the presence of the *B. aerogenes capsulatus* group, the streptococcus group, the staphylococcus group, the *B. pyocyanus* and diphtheroid bacilli. No attempt was made to classify the varieties of any group.

The percentage incidence of each group at the various periods of examination is given in Table III. This percentage is the average of the whole number of cases treated by all the dressing solutions. About 50 cases which remained on dry dressings throughout the same period showed almost identical percentages for each group as those given in the table.

TABLE III.—Percentage Incidence of Certain Groups of Organisms in Chronic Suppurating Wounds.

No. of cases.	Day.	<i>B. aerogenes capsulatus.</i>	Strepto-cocci.	Staphy-lococci.	<i>Pyocy-anus.</i>	<i>Proteus</i>	Diphther-ooids.

612	—	5 average	68 average	61 average	39 average	28 average	18 average
Easams.	—						

There are several points of interest which may be noted from an analysis of Table III. First, the percentage incidence for streptococci, staphylococci, and the *B. proteus* is remarkably constant throughout the period of observation. This is specially marked in the case of streptococci, which does not vary more than 4 per cent. In the case of the gas bacillus, the *B. pyocyanus*, and the diphtheroid bacilli, there is a slow decline in incidence from the first to the last examination, although in the case of the *B. pyocyanus* there appears at first to be a slight increase in frequency. The low percentage of the gas bacillus throughout the series is that to be expected in cases which come under observation after the acute stage is past.<sup>2</sup>

A summary of these examinations furnishes a fairly definite standard with which to compare the incidence of these groups of organisms in the cases treated with each dressing solution. The percentages are so constant that any marked variation under any particular treatment becomes readily apparent.

Among these dressings were; (1) Dakin's solution, quinine hydrochloride, 0·5 per cent.; (2) physiological saline; (3) hypertonic saline, 5 per cent.; (4) hypotonic saline; (5) acetic acid, 1 per cent.; (6) bicarbonate of soda, 1 per cent.; (7) cresol, 1/10 per cent.; (8) benzoic acid, 0·5 per cent.; each of the last four being made up with a basis of physiological saline.

No one of these solutions affected the percentage incidence of all the groups of organisms listed in Table III. As is perhaps to be expected, physiological saline produced no alteration in the percentage incidence of any group. The cases under certain other solutions, however, showed distinct variations in the incidence of one or more groups of organisms. This may be best shown by the charts of each organism and its occurrence among the cases under those solutions as compared with the average percentage. Table IV. shows only those variations from the average which are worthy of comment. The solutions which failed to alter the incidence of an organism are omitted from the table of that group.

In the case of the *B. pyocyanus* there was an increase in incidence of the organism in the series of wounds dressed by Dakin's solution, quinine hydrochloride and bicarbonate of soda; and a sharp decrease in those dressed by acetic acid. This is in harmony with the clinical observations as well as with the *in vitro* tests. The occurrence of green pus has been frequently observed with the three former solutions,

<sup>2</sup> Observations on the Pathology and Bacteriology of Gas Gangrene, Journal of Pathology and Bacteriology, vol. xx., 1916.

and the use of acetic acid has proved very efficient in eliminating it.<sup>3</sup> The streptococcus group showed a slight decrease with the bicarbonate dressings. No effect appears to have been produced upon the incidence of the organism by the other dressing solutions, with the exception of cresol.

TABLE IV.—Percentage Incidence of *B. pyocyaneus*, *Streptococci*, *Staphylococci*, and *B. aerogenes capsulatus* (Welch) in Wounds under Various Dressing Solutions compared with the Average Incidence of each Organism.

Day examined.	<i>B. pyocyaneus</i> .				<i>Streptococci</i> .				<i>Staphylococci</i> .				<i>B. aerogenes capsulatus</i> .

and hypotonic saline, where there seems to have been a slight increase in the percentage.

Staphylococcus showed a slight decrease among the cases dressed with Dakin's solution or cresol. It seems to have been little affected by the other dressings.

In the case of the gas bacillus no effect seems to have been produced by any of the dressing solutions with the exception of quinine, where the early disappearance of the organism was strikingly apparent. This result is consistent with earlier experience with this alkaloid, both *in vitro* and in clinical application.<sup>4</sup> With this organism there appeared to be a higher incidence among the cases on dry dressings than among those on any of the dressing solutions.

In spite of the fact, therefore, that our methods of applying antisepsics are still very inadequate and their efficiency as dressing solutions greatly hampered, definite effects on the bacterial flora of the wounds were obtained. Furthermore, these effects were evidenced in no case upon the bacterial flora *in toto* but upon one or more species of bacteria at a time—those for which the dressing was most specific. The failure to produce a greater effect upon the streptococci and staphylococci may have been due to a deeper distribution of these organisms in the tissues, or, the other factors being equal, to the failure to use an antiseptic having an exceptional bactericidal value for those particular groups. Possibly a wider choice of dressing solutions would have shown antisepsics with this property.

#### Summary.

It has been suggested that the specific method of treatment is applicable to wound infection as well as to systemic infection. Some instances of the variation of antisepsics in their activity against different bacteria *in vitro* have been offered in support of the principle. A large number of bacteriological examinations of wounds under treatment with different solutions has been recorded and instances of the specific action of certain dressing solutions demonstrated.

It is believed that further analytical study of antisepsics will result in the discovery of dressings specific for one or more groups of bacteria. By a successive application of these dressings the organisms present in the wound may be reduced in number or eliminated one variety at a time, and true sterilisation of a suppurating wound accomplished. But first the concept of the "general antiseptic" must go by the board and the search for a cure-all be recognised as unprofitable.

It is a pleasure to express my acknowledgments to Dr. Joseph A. Blake for his advice and criticism, and to Miss Mary Davies and Dr. B. H. Buxton for their large share in the technical part of this work.

## INTESTINAL PROTOZOA IN SALONIKA WAR AREA.

BY LIEUTENANT W. ROCHE, R.A.M.C.,  
PROTOZOLOGIST, SALONIKA WAR AREA.

(Report to Medical Research Committee.)

DURING the months of August, September, and October, 1916, I had the opportunity of examining the stools of 893 cases of diarrhoea and dysentery among the troops of the Salonika war area. Some of these cases had their stools examined two or three times weekly, but the great majority of them not more than once. This work was all part of the routine laboratory examination of stools of patients suffering from diarrhoea or dysentery in three of the general hospitals in this area.

Troops of the Salonika zone of the Eastern Mediterranean have suffered severely from diarrhoea and dysentery. These infections started about the month of May, 1916. They have continued, with slight variations, up to the present. These variations, I think, are mainly due to climatic changes. The great spreaders of diarrhoea and dysenteries are flies. Heat and moisture are necessary for these pests to thrive. In the very hot spells, when everything was dried up, flies became less numerous. On the contrary, during a cold spell, their numbers were markedly diminished, and in these periods there was decidedly less diarrhoea and dysentery.

Bacillary dysentery was the predominant type, but there were quite a number of acute amoebic cases. It is a remarkable thing there were not more, inasmuch as many of the troops, particularly those which had come from Gallipoli and Egypt, were carriers of *Entamoeba histolytica*. Microscopical examinations of the stools of these troops in Egypt, Malta, and Salonika continually showed evidence of this.

#### Table of Findings.

Number of cases examined, 893; number of examinations, 1425.

E.F.	Non-pathogenic amoebae (81).		Pathogenic amoebae (84).		Flagellate protozoa (217).				Coccidia (18).	
	Ent. hist.	Ent. hist. cystis.	Ent. hist.	Ent. minuta	Ent. min. cysts.	Lamblia	Lamblia cystis.	Tetramitus.	Tetram.	Cerco-
39	42	39	21	16	29	18	29	44	72	18

By E.F. (free amoebæ), we mean amoebæ found in fresh specimens of stools in a resting or precystic stage. This group includes cases in which there was no time for staining, nor was further examination possible for a more complete diagnosis.

#### Amoebic Dysentery.

As is seen in the above table, *Ent. histolytica* was present in 37 cases. In two of these it was found post mortem. In one the patient died two hours after admittance to hospital. There were six perforations in the large gut and typical lesions of acute amoebic dysentery, from which different scrapings showed large numbers of *Ent. histolytica*. This patient had never been in Egypt or Gallipoli or other infected area, and he did not belong to a division that had been in one, nor was he in camp with any troops known to be infected.

The second case died from sepsis, the result of a severe gunshot wound of the thigh. In the routine post-mortem examination of the organs the gut showed signs of acute amoebic dysentery, and scrapings from it showed *Ent. histolytica*. This patient had also never been in any infected area.

In cases where *Ent. minuta* was found a history of recurrent diarrhoea was usually given. The stools were faecal with mucus, but seldom was there blood. These patients, one generally found, had been in Gallipoli or in Egypt. As well as the *Ent. minuta*, but included in the table under that category, I found in a few cases a specially small form of amoeba with its cyst, a type which had been demonstrated to me in Egypt by Lieutenant-Colonel Wenyon, R.A.M.C., and which has been described by him. Cases

where any type of *Ent. histolytica* was found in the stools were treated in the ordinary way with emetine (1 gr. hypodermically daily for 12 days).

War-time exigencies did not allow of all patients being retained in hospital after their course of treatment was concluded, so that further examination for cysts was impossible. Seven patients, however, in whose stools *Ent. histolytica* cysts were found to persist after their emetic course were further treated with Dale's double iodide of emetine and bismuth. These cases were discussed in THE LANCET of Jan 6th, p. 17. Eight of the *Ent. histolytica* patients had also a bacillary infection. In all but one it was of the Flexner type.

*Ameba coli*, considering how commonly they are found in the gut, may be said to have been present only in a small percentage of cases.

#### Flagellate Protozoa.

In almost all cases where any of the flagellate protozoa were found there was mucus mixed with faecal matter; in a very few cases there was blood and mucus only. *Tetramitus mesnili* was the flagellate most commonly present, more often in its flagellate than in its cystic stage. This was due, I think, to the fact that the patient's stool was examined soon after the diarrhoea commenced and before the slowly-forming oysts had time to develop. Repeated examinations of the stools were not possible, but in patients who remained in hospital for some time, and in whom further search could be made, *tetramitus* cysts were found.

*Lamblia intestinalis* was a common infection, the cystic form being more often present than the flagellate form. This is due, I think, to this fact, that lamblias attaching themselves by their suckers to the mucous membrane of the duodenum and jejunum are difficult to detach therefrom by the action of drugs. On the other hand, their cysts, which are free and mixed up with the intestinal contents, are readily washed down by aperients. Five of the cases of lamblia infection I was able to examine weekly during three months, and despite all treatment they continue to discharge lamblia cysts up to the present time.

*Trichomonas* was found in comparatively few cases. This is peculiar, as this parasite is so often present in the stools of people living in tropical and subtropical climates. In one case where I found trichomonas and cercomonas flagellates in the stools of a patient who subsequently died from pyæmia these flagellates were found post mortem, both in scrapings from the large bowel and in the faecal contents.

*Coccidia* were found in 18 stools. In this infection mucus was always present in the stools. As a rule, these parasites disappeared within a few days, but in one patient they were found in daily examinations for three weeks.

The lamblia and *tetramitus* infections were the most difficult to get rid of. Calomel, bismuth, thymol, salol, turpentine, emetine, and Dale's double emetine were amongst the drugs tried without any result. Rectal irrigations with quinine, turpentine, eusol did not lessen the infection.

## METHOD OF PLASTER SPLINTING FOR THE TREATMENT OF KNEE-LESIONS.

BY GEORGE DAVIS, M.D., B.S. DURH., M.R.C.S., &c.,  
CAPTAIN, R.A.M.C., SURGICAL SPECIALIST TO THE MILITARY HOSPITAL, EASTBOURNE.

ESSENTIALLY this method is a thigh plaster and leg plaster conjoined by three equidistant arches of hoop-iron. The points of the method are:-1. That the interrupting supports radiate from a point in the centre of the limb and resist mobility equally in all planes. 2. The iron-hoops being covered with plaster become one with the splint, are much strengthened and much smoother, and less awkward. 3. There is quite free room for dressings, however bulky. The splint can be made much more serviceable by having an extension of plaster around the pelvis—a spica. The technique is the outcome of my own attempts.

The splint is especially suitable for all cases of long-continued suppuration of the knee and for cases of resection of the knee-joint. Also where the tibia is fractured into the knee or where infection has reached the joint from a wound in the tibia. It will be most useful where fibrous ankylosis

is the best prognosis permissible from the nature of the injury. Such cases often last many months, entailing intense suffering. Unless the limb is fixed without mobility a bad alignment results from muscular action, when the ligaments of the joint are softened by long-continued suppuration. I have seen such dislocations outwards and backwards, and the only possible treatment was to amputate at the thigh.

The only other splints that would occur to any surgeon in this class of case are: The Wallace-Maybury; this is bad, since it tends to separate the opposing bony surfaces of the joint, and it allows the knee to sag down at each dressing. The same remarks apply to the Thomas. Of course, the use of the Balkan splint with this splint is obviously the best treatment in conjunction with this fixing apparatus.

The materials required are:—

1. For covering the leg: two cotton bandages, one flannel roller, and four strips of mackintosh 7 in. wide and of sufficient length to encircle the limb, with 2 in. overlap at each of the four edges of the plaster splint.
2. Eight plaster bandages and some 2 or 3 lb. of loose plaster, three bowls, a wooden stirrer, and some warm water.
3. A piece of charcoal or charred stick for marking the leg and the plaster, &c.
4. The iron-hoop arches made with flanges for fixing are of the following gauge and dimensions: Breadth, 1½ in.; length, the arch span, i.e., the distance of 2 in. above and below the extreme wound, included. The flanges 3½ in., and turned slightly upwards at their extreme end. The arch is to be 4 in. high, and the sides of the arch drop vertically to the flange. The gauge should be ½ in., and if made of malleable iron can be easily bent and adapted by the fingers.
5. Half-pint of boiled linseed-oil "driers," ½ pint of spirit varnish, and two brushes to apply these.
6. Some strapping to fix the endings of bandages, &c.

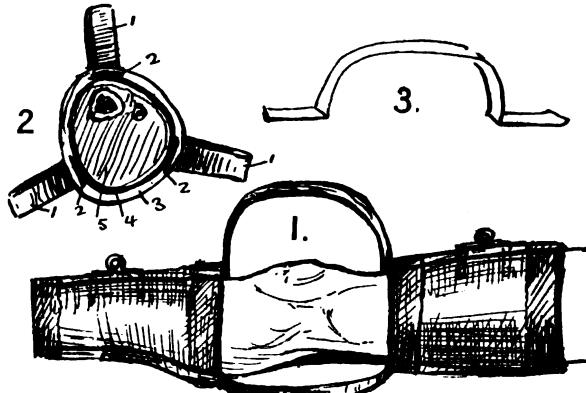

FIG. 1.—Inner side of leg and thigh, showing splint applied and coat-sleeve mackintosh and rings of wire to affix to Balkan.  
FIG. 2.—Section of leg seen from below with plaster and iron arches.  
1. Arches of hoop-iron. 2. Flanges in thickness of plaster. 3. Plaster of Paris. 4. Flannel roller. 5. Section of upper part of leg.  
FIG. 3.—The hoop-iron arches.

The detailed technique is as follows (Figs. 1-3):—

1. Anæsthetise the patient.
2. Mark the limits to be reached by the plaster. Dress the wound and bandage firmly. Pass a cotton roller over the area to be covered by the plaster, at the same time fixing the mackintosh strips, and protecting any old healed wounds, that will be covered by the plaster, with gauze squares. Over this put a layer of flannel roller, fastening off with a piece of strapping.
3. Plaster bandages are applied to the thigh and leg, above and below the marks, and made of three thicknesses of bandage. This must "set" before proceeding.
4. Sling the limb to the Balkan splint and have two capable persons to hold the limb both as to lateral form and axial alignment, under the continued supervision of the surgeon.
5. The irons are covered with a layer of cotton bandage and marked 1, 2, and 3 at their upper flanges. Take them in order, and having marked with charcoal three equidistant lines on the newly set plasters, fit each iron to its proper place by slight bending and axial twisting. When they ride truly make a complete outline of the site of each on the plaster, numbering each place.
6. The irons are now fixed, first all at one end and then at the other, by means of plaster bandages; further bandages are added until a thickness giving the required stability is

produced. The leg splint need not reach lower than to 4 in. above the malleoli.

7. Each metal bridge is now covered with plaster bandage round and round, until by working the surface with wet fingers the required smoothness is attained and the junction with the splint made perfect.

8. The mackintosh slips are turned back coat-sleeve wise, the stuff being cut when interrupted by the irons. The various parts are slightly fixed with strapping.

9. When quite dry the driers are applied, and over this, when hard, the spirit varnish, all over the whole plaster surface. This makes it resistant to everything short of continual soaking or the abundant use of peroxide of hydrogen, and prevents the troublesome shedding of powdery particles from the plaster surface.

The splint so prepared should be very comfortable and a welcome support. It should last 4 to 7 weeks, by which time further progressive emaciation of the limb may require a fresh splint to be made. The limb, splint and all, is slung from a Balkan frame. The dressings can be done with the minimum of pain, and the perfect alignment of the limb is assured. The patient can bear to have the limb handled and be moved on to a couch or spinal chair and so improve in health and spirits by being out in the open air.

It is easy to make additions to this apparatus, either of a plaster to include the foot or one to surround the pelvic girdle, or both.

My acknowledgments are due to Major Madrange, A.M.C., 1st Army Corps, and to Colonel G. S. Robinson, S.G., O.C. i/c Military Hospital, Eastbourne, for permission to publish this paper.

## NOTES ON THE STARVATION TREATMENT OF A YOUNG DIABETIC.

BY P. C. COLLINGWOOD FENWICK, L.M.S.S.A. LOND.,  
HOUSE PHYSICIAN, ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON.

*Remarks by E. HOBHOUSE, M.D. Oxon., F.R.C.P. Lond., Lieutenant-Colonel, R.A.M.C., T., Physician to the Hospital.*

A BOY, aged 16, admitted to the Royal Sussex County Hospital under Lieut.-Col. Hobhouse on Jan. 8th, 1916, complained of great thirst and wasting; this had been going on for two months. Family history excellent; no other member had had diabetes. He remained in hospital 6 weeks on full diet except that bread, sugar, potatoes, and fruit were allowed in very small quantities. On admission he weighed 6 st. 10 $\frac{1}{2}$  lb.; when discharged on Feb. 15th he was 1 lb. heavier. The reports on his urine on admission and when he left were: specific gravity, 1042, 1030; acid; sugar, 4 $\frac{1}{2}$  per cent., 4 per cent.; acetone and diacetic acid absent. Treatment with bile and pancreatic tablets had no effect on the amount of sugar in his urine.

On July 7th he was readmitted with a view to trying the starvation treatment. He was very much the same as when he went out, but had lost a pound in weight. Urine: specific gravity 1035, acid, sugar 4 per cent., no acetone or diacetic acid. He was kept to bed for a fortnight, when he was up on a chair for a short while. Each day he was allowed to do more, until by the time of discharge he was taking long walks morning and afternoon. His urine, on admission very acid, was kept neutral all the while by bicarbonate of soda, as much as 50 grains being given every four hours at one time.

The following shows his variation in weight during his stay of two months. He was weighed naked early in the morning after he had passed urine on each occasion.

July 23 ...	6 st. 10 lb. 4 oz.	Sept. 3 ...	7 st.
" 30 ...	6 st. 9 lb. 8 oz.	" 10 ...	7 st. 2 lb.
Aug. 6 ...	6 st. 4 lb.	" 17 ...	7 st. 3 lb.
" 13 ...	6 st. 7 lb. 8 oz.	" 22 ...	7 st. 6 lb. 8 oz.
" 20 ...	6 st. 9 lb. 12 oz.	" 28 ...	7 st. 10 lb.
" 28 ...	6 st. 12 lb. 8 oz.		

From August 6th to Sept. 25th he gained over a stone in weight. During this time his urine did not reduce Fehling's solution, and only by a more delicate test could a trace of sugar be detected occasionally. He left the hospital on Sept. 25th in perfect health, with no sugar, acetone, or diacetic acid in his urine, and with his weight increasing weekly.

Since leaving hospital four months ago the boy has gained 2 $\frac{1}{2}$  lb. in weight, has started learning motor engineering, and his urine still remains free from sugar, acetone, and diacetic acid.

(1) July 25th:—6 A.M.: cocoa (with little milk) 8 oz., 1 egg. 9 A.M.: black coffee 6 oz., whisky 2 dr. 12.30 P.M.: lettuce; greens or cucumber; 1 egg. 4 P.M.: tea (with little milk) 8 oz. 7 P.M.: lettuce or cucumber; black coffee 2 dr.

(2) August 1:—6 A.M.: cocoa 8 oz., 1 egg. 9 A.M.: black coffee 6 oz., whisky 2 dr. 12.30 P.M.: meat 3 oz., greens. 4 P.M.: tea 8 oz. 7 P.M.: lettuce or cucumber; black coffee 6 oz., whisky 2 dr.

(3) August 5th:—6 A.M.: Cocoa 8 oz., 2 rashers of bacon, 2 eggs, lettuce. 9 A.M.: Black coffee 6 oz., whisky 2 dr. 12.30 P.M.: Meat 4 oz., greens; custard pudding (unsweetened); 1 apple. 4 P.M.: Tea 8 oz., 1 egg.

7 P.M.: Soup  $\frac{1}{2}$  pt. or boiled macaroni; lettuce. 8.30 P.M.: milk  $\frac{1}{2}$  pt.

(4) August 20th:—6 A.M.: Cocoa 8 oz., 1 roll gluten bread, 3 rashers of bacon, 2 eggs; or fish and 2 eggs; cucumber or lettuce. 9 A.M.: Coffee and milk 8 oz. 12.30 P.M.: Meat 6 oz., greens; 1 apple or banana; custard pudding; milk  $\frac{1}{2}$  pt. 4 P.M.: Tea 8 oz., 1 egg, 1 roll gluten bread, butter 1 oz. 7 P.M.: Soup  $\frac{1}{2}$  pt. or boiled macaroni; 1 apple or banana; 1 roll gluten bread, butter 1 oz., cheese 1 oz. 8.30 P.M.: Milk  $\frac{1}{2}$  pt., 1 water biscuit.

(5) Sept. 4th:—6 A.M.: Cocoa and milk 8 oz., 3 rashers of bacon, 2 eggs, or fish and eggs; 1 roll of gluten bread; 1 apple or banana. 9 A.M.: Coffee and milk 8 oz. 12.30 P.M.: Meat 6 oz., greens; rice, sago, or tapioca pudding; 1 apple or 1 banana; 1 roll gluten bread; milk  $\frac{1}{2}$  pt. 4 P.M.: Tea and milk 8 oz., 1 egg, 1 roll gluten bread, butter 1 oz. 7 P.M.: Soup  $\frac{1}{2}$  pt. or boiled macaroni; 1 apple or banana; 1 roll gluten bread, butter 1 oz., cheese 1 oz. 8.30 P.M.: Milk  $\frac{1}{2}$  pt., 1 water biscuit.

*Remarks by Lieut.-Col. HOBHOUSE.*—The above account is of interest as showing the effect of starvation on a class of cases which are usually of a very hopeless character. The credit of managing and regulating the diet belongs entirely to Mr. Fenwick. One point of some interest is that acetone and diacetic acid were absent until the starvation diet was commenced, and then continued to appear intermittently for over three weeks, sugar being generally absent. I do not know what the explanation of this may be, whether it is due to the starvation itself or to something in the diet. The quantities present were always small. The case cannot be classed as one of the most severe, though the emaciation and weakness were great when the boy came in for the second time.

**CITY OF LONDON TRUSS SOCIETY.**—At the annual general meeting of this society, held on Feb. 7th at 5, Finsbury-square, it was stated that 5221 patients had been treated during 1916 and that 1100 trusses had been specially made to order.

**THE CONTROL OF TUBERCULOSIS IN IRELAND.**—Our Belfast Correspondent writes: At a recent meeting in Omagh Dr. E. C. Thompson drew attention to the bad effect of sending advanced cases of pulmonary consumption from the County Tyrone Sanatorium Home, a course which simply leads to spreading of the disease. It is to be feared that this practice, combined with the farcical type of notification of tuberculosis in vogue in Ireland, will in the end lead to very slight improvement in the incidence of the disease.

### ROYAL SOCIETY OF MEDICINE.

#### SECTIONS OF OTOTOLOGY AND NEUROLOGY.

##### *War Injuries and Neuroses of Otological Interest.*

A MEETING of the Section of Otology, to which members of the Section of Neurology were invited, was held on Feb. 16th, when a discussion on the above subject was opened by Mr. H. J. MARRIAGE, President of the Section of Otology.

Mr. MARRIAGE said that his remarks were based upon notes of cases kindly sent to him by Mr. Arthur Cheatle, Mr. E. D. D. Davis, Mr. Somerville Hastings, Mr. Pike, and Dr. W. S. Syme, and also on an excellent paper published by Mr. Logan Turner, Mr. J. S. Fraser, and Mr. W. G. Porter, a copy of which was sent to him by Mr. Fraser, in addition to cases which he had seen himself. The subject was dealt with under four main headings, a number of illustrative cases by various observers being recorded. I. (a) Wounds of the auricle. In these cases all that was usually required was to clean up the wound, remove fragments of metal, and apply antiseptic dressings. If the damage was very extensive it was often possible to save the greater part of the ear by performing a plastic operation. (b) Wounds of the external meatus were usually caused by missiles which entered either in front or behind the ear and passed right through the meatus; the cartilaginous meatus appeared most frequently affected, though at times the bony canal might also be damaged. In its course the missile often injured the facial nerve and might also injure more or less the mastoid process. Cicatricial stenosis of the meatus very commonly resulted in these cases if there was extensive injury and would cause some deafness, and there might be some internal ear deafness. II. Injuries of middle ear. Rupture of the tympanic membrane had been very common, mainly due to high explosive. The perforation occurred in the membrana tensa; the rupture seemed to be most frequent in the lower half of the drum. The size varied from a small pin's head to the loss of half the drum. In cases seen within a few days of the injury the edges were ragged and covered with dried blood, but later the edges became quite smooth. The commonest symptoms were marked deafness with at times loss of consciousness for a few minutes and often slight bleeding from the ear which might be followed by a little serous discharge; rarely there might be tinnitus and slight vertigo due to involvement of internal ear. In most cases when tested with tuning-fork (C) even a few days after injury bone conduction was normal, but air conduction was diminished, varying according to extent of damage; in several cases air conduction was also slightly subnormal when tested with tuning-fork (C'). Complete loss of hearing had not been observed in any reports which had come under the speaker's observation. If no suppuration took place he found healing occurred in 1 to 3 months; E. D. D. Davis gave the time as 5 to 10 weeks. As regards the frequency of middle-ear infection Mr. Marriage was not able to give any satisfactory statistics, but in the cases seen by him about 30 per cent. had discharge when admitted to hospital over here. The majority healed quite well, with good recovery of hearing; two cases required operation on the mastoid. The usual treatment for ruptured drums adopted over here had been to disinfect the meatus and to keep it plugged with gauze or wool, avoiding all syringing and drops. Somerville Hastings reported an interesting case of hemorrhage into the middle ear, and Cheatle also reported a case due to parachute descent. Nothing was done in the way of treatment, and in about a month the blood had become absorbed and the hearing had returned. III. Injuries of internal ear. (a) Direct injury of labyrinth by a missile. These wounds as a rule were fatal, but in a few cases the patient had survived, and Cheatle had reported a particularly interesting one, in which a rifle bullet entered the left temporal region above the zygoma and emerged just to the left of the second cervical vertebra. (b) Indirect injury of labyrinth in fracture of skull might be caused by falls, blows on the head, or by bullet wounds. Syme and Fraser state in their paper:—

If the force is applied at the side of the head in the direction of the petrous pyramid we get a longitudinal fracture

which usually runs along the roof of the middle-ear cleft and, as a rule, in these cases the labyrinth capsule remains intact; if, on the other hand, the force is applied at the back of the head we get a transverse fracture which runs at right angles to the long axis of the petrous pyramid and always injures the labyrinth. As a rule, these fractures pass through the vestibule. The symptoms of such injuries are extreme or total deafness, marked disturbance of balancing, with loss of the cochlear and vestibular functions. If the labyrinth is injured there is an escape of cerebro-spinal fluid along with the blood. In the cases in which the labyrinth capsule is not injured there is no escape of cerebro-spinal fluid; but, nevertheless, deafness results from haemorrhage into—or tearing of—the eighth nerve. One or two of the cases with fracture of the labyrinth have been microscopically examined many years after the accident, and filling up of the hollow spaces of the labyrinth by new connective tissue and bone has been found, along with secondary degenerative atrophy of the nerve structure.

(c) Concussion deafness might be due to constant gunfire day after day or to explosion near the patient of a shell. In the former case, in the speaker's experience, a slight amount of permanent deafness usually persisted after frequent exposure to noise for long periods. The deafness due to the explosion of a shell was generally for a short time very severe and at times the patient had been rendered unconscious, but as far as he knew the deafness had never been absolute. The symptoms and state of hearing were described. The drums were normal. A large proportion of these patients recovered their hearing in the course of one or two months, but others improved very little. The treatment he had adopted in these cases was complete rest in bed, with the administration of bromides in the early stages and later strychnine. As regards prognosis, as far as he could judge from cases seen, if marked improvement did not occur within six to eight weeks the outlook was distinctly bad. Even when the hearing returned tinnitus often persisted. The exact lesion was probably chiefly peripheral. IV. Psychical deafness was usually bilateral and was commonly seen in those who had suffered a severe shock—e.g., by being buried by a shell—without any visible injury. Deafness was usually absolute, nothing being heard either by air or bone conduction. It was generally accompanied by other nervous signs and symptoms, such as loss of voice, narrowing of the field of vision, tremors, irregular paralyses, and areas of anaesthesia. Spontaneous nystagmus was absent. These cases often recovered with a counter-shock, with rest and massage, or by giving an anaesthetic; at times asafoetida and valerian were useful. To distinguish this form of deafness from malingering was sometimes difficult, but it could generally be accomplished if a thorough examination was made. Finally, he said he believed that obturators were of distinct benefit in saving the hearing, and that one of the simplest and best forms was plasticine wrapped in gauze; this could be moulded to the shape of the external meatus, and was easily put in and withdrawn. Plugs made of celluloid should never be used.

Mr. SYDNEY SCOTT showed (for Mr. J. S. FRASER) an interesting series of photomicrographs of cases in ear injury.

Colonel H. F. BIRKETT, C.B., spoke of the work which had been done at his hospital, in conjunction with Dr. Gordon Wilson, in which institution were 55 beds set apart for this class of injury. He briefly indicated the lines on which the various cases were treated.

Dr. GORDON WILSON said he had the records of over 100 cases of nerve deafness, and he had seen in France a number of cases of concussion deafness soon after the condition occurred. The cases of ear trouble were divided into three groups: (1) cases of nerve deafness; (2) cases with a fixed idea that they could not hear; (3) malingerers. Some cases presented the problem as to whether they were cerebellar disease or labyrinthine wound. Some of the most difficult cases had been those in which the facial nerve had been cut outside the ear.

Mr. O. E. WEST referred to cases in which both the hearing and the visual fields were contracted in the same patient. Though he had done a considerable amount of war work, there were comparatively few cases of direct injury to the ear. He narrated several interesting cases.

Dr. DUNDAS GRANT also remarked on the few cases of clear-cut labyrinthine injury in the war. When the tympanic membrane was ruptured involvement of the labyrinth had been but slight. He discussed the guides to prognosis which he had found useful in his cases, and traversed the general subject.

Major G. P. SHUTER, Dr. C. E. JONES-PHILLIPSON, Mr. SYDNEY SCOTT, Mr. E. D. D. DAVIS, Mr. HUNTER TOD, Mr. SOMERVILLE HASTINGS, and Mr. W. M. MOLLISON continued the discussion.

#### SECTION OF PATHOLOGY.

*The Central Nervous System in Hypothyroidism.—An Anatomical Abnormality Inherited from the Fifteenth Century.—Congenital Hypertrophy.*

A MEETING of this section was held on Feb. 13th, Professor F. W. ANDREWS, the President, being in the chair.

Professor F. W. MOTT read a paper on the Changes in the Central Nervous System in Hypothyroidism. The nervous symptoms of myxedema, he said, pointed to a condition of exhaustion of nervous energy, which could be remedied by the administration of thyroid gland. Consequently, upon the assumption that the basophil substance of the nerve cell is a source of nervous energy, one would expect to find what he had actually found in seven cases—viz., a marked chromatolysis, which in sections of the brain and spinal cord was revealed by the partial or complete disappearance of the Nissl granules throughout the central nervous system. Six of the cases had already been recorded. The chromatolytic changes were universal, sparing no system or group of systems of neurones entirely, but had been especially noted in the smaller cells of the autonomic nuclei—e.g., the vagus and glosso-pharyngeal. The cells of the olfactory body showed much less change, and the Purkinje cells of the cerebellum less change than the large motor cells of the medulla oblongata, spinal cord, and Betz cells of the cortex, and there was no increase of neuroglia. All the asylum cases, especially four of the five, showed marked chromatolysis of the cortical cells; the one that manifested the least degree of mental confusion and other signs of insanity exhibited the least change in the cortical cells. The lantern slides of the seventh case, not hitherto described, showed very marked changes, and the mental symptoms were most pronounced. He had come to the conclusion that there was a type of insanity in women about the climacteric, in which a manic-depressive condition, associated with mental confusion, hallucinations, delusions (mainly of persecution), loss of memory of recent events, and terminating in dementia occurred, and which might arise as a result of a particular form of hypothyroidism. It was characterised by: 1. An atrophy of the glandular structure of the thyroid, interstitial fibrous hyperplasia, and abundant infiltration of the gland with lymphocytes—a condition of chronic inflammation arising from a toxic condition, probably local in its source, as Kojima had shown. The adjacent parathyroids did not exhibit this change. 2. An increase in weight of the pituitary gland as a rule. There was an increase of the pars intermedia, as had been demonstrated by Boyce and Beadles, and later by Herring, in experimental hypothyroidism. Herring had shown that the cells of this structure invaded the pars nervosa, and this had occurred in the case, the seventh, now being described. All five cases of hypothyroidism, in which the pituitary was examined, showed an excess of colloid in the pars intermedia. The characteristic perinuclear chromatolysis of the nerve cells found in these cases was not seen in two cases of simple atrophy of the thyroid gland. Examination of the thyroid in these two cases showed still normal colloid vesicles, and although there was an increase of fibrous tissue, there was no lymphocytic infiltration indicative of a local toxic inflammation, nor was there any increase of the pars intermedia or colloid material of the pituitary, observed by Kojima. It had, however, always to be considered how far the atrophy of a gland and failure of its function might act in upsetting the bio-chemical balance existing between the secretions of all the ductless glands and the sexual glands. In the five asylum cases, in which the suprarenal glands had been examined, a deficiency of lipid in the cortex was observed, but it would be unscientific to correlate this condition definitely with the thyroid atrophy, for the patients had died usually from some acute infective disease, and Elliot had shown that in deaths so occurring the lipid is diminished. Kojima, in his exhaustive examination of all the ductless glands in three cases, came to the conclusion that he could exclude the probability that changes in any ductless glands other than the thyroid could be responsible for the nervous and mental symptoms and the histological changes in the central nervous system. It was noted, however, that the

ovaries were affected in three cases, and these were those in which there was not merely a glandular atrophy, but also a marked chronic inflammatory interstitial change. In the new case there were extraordinarily large ovaries and an enormous number of corpora albicantia, but healthy Graafian follicles were present. The blood and cerebro-spinal fluid gave a negative Wassermann reaction in all the cases.

Dr. H. DRINKWATER recorded a peculiar Abnormality of the Fingers which had been transmitted through 14 generations. The thumb and index finger were normal. In the middle finger the terminal joint was free, but the proximal interphalangeal joint was only slightly movable. In the ring and little finger the first and second phalanges were quite continuous. The hands were symmetrically affected. All the toes, excepting the hallux, were affected like the ring and little fingers. The patient's father had married twice. One of the patient's half-brothers presented the same abnormality, as did also his father and paternal grandfather. The patient himself was a direct descendant in the male line from the first Earl of Shrewsbury (d. 1453), and when the body of that nobleman was exhumed in 1874 it had been discovered that the fingers exhibited a similar variation. The mode of the inheritance of the malformation among the recent members of the family showed it behaved as a Mendelian dominant. Dr. Drinkwater did not think that there was any genetic relationship between this condition and brachydactyly.

Dr. H. S. STANNUS communicated an account of a case of Congenital Hypertrophy of a Lower Limb, which occurred in a native of the New Langenburg district, German East Africa, a man about 17 years old. The right lower limb was larger than the left at birth, the disproportion being maintained during growth. The length, as measured from the anterior superior iliac spine to the tip of the external malleolus, was 101 cm., as compared with 84 cm. on the left side. Skiagrams showed that the bones participated in the enlargement.

#### MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

##### Dreams and Their Interpretation.

THE ordinary quarterly meeting of the Association was held at the Medical Society's rooms, Chandos-street, Cavendish-square, W., on Feb. 15th, Lieutenant-Colonel DAVID G. THOMSON, the President, being in the chair.

The PRESIDENT made sympathetic reference to the decease of a number of members since the last meeting, including Dr. William Orange, C.B., of Broadmoor, and a former President of the Association. He then offered the Association's congratulations to Sir Robert Armstrong-Jones on the honour of knighthood which he had received, and to Dr. John Warnock, the distinguished worker in lunacy in Egypt, who had been awarded the distinction of the Order of St. Michael and St. George. He added that Captain D. H. Pennant, a former assistant medical officer at Barnwood House Asylum, Gloucester, had been awarded the D.S.O. and Dr. P. M. Turnbull, formerly of Tooting Bec Asylum, the Military Cross.

Sir ROBERT ARMSTRONG-JONES having briefly acknowledged the congratulations of the Association, which he greatly valued, read a paper entitled "Dreams and Their Interpretation, with Reference to Freudian." He said that it was claimed by many that the interpretation of dreams helped to bring out of the unconscious mind what is perplexing and hidden, and restored the balance in the unstable and in those suffering extensively from mental shock. Freudians, he added, considered a dream as the symbol of an unfulfilled wish, which had to be interpreted by an assumed psycho-analytic code, but in his view the dream did not always, as assumed by Freud, refer to sex matters. The fact that dreaming could be induced by such agents as opium, alcohol, and tobacco favoured the view that it was a morbid process. There was, he said, good reason for the belief that most dreams occurred just before waking, while the age of greatest dreaming was between 20 and 25, and women, who slept more lightly, dreamt more than men. He thought that the sexual theory of dream-causation was over-emphasised, the psycho-analyst always finding what he sought, while he considered that the foreign teachers responsible for employing the "sex-mad methods," and the craze for new excitement,

have in this country already received posthumous recognition of their labours, for, thanks largely to the efforts of Dr. Mercier, Freudism in this country was practically dead.

Sir GEORGE SAVAGE, as a persistent dreamer and therefore with a wide experience, spoke of the very short time occupied by an elaborate dream, which he had been able to prove on more than one occasion.

Mr. ROTHSAW STEWART had found, after some practice, that he could trace every dream he had to something which had occurred before.

Colonel J. W. SPRINGTHORPE spoke of the many cases of shell-shock with which he had had to deal, in which he did not doubt that in 99 per cent. the cause was fright. Freud, in his wholesale attribution of dreams to sex matters, had made an unutterable mistake which was practically an insult to humanity.

Dr. J. G. SOUTAR remarked that British alienists did not proceed to examine everything in the light of a pre-conceived idea. It would be easy to discover some connexion with sexual matters in everything; but it was needed that such ideas should not prevail in the mind of the investigator. Such an interpretation of dreams was contrary to experience. He had found that when insane patients began to have happy dreams, it augured well for recovery.

Dr. ALICE JOHNSON pointed out, in opposition to the Freudian idea, that the mind could be made by psycho-analysis more the reservoir of beautiful things, and such a mind would dream beautiful dreams.

Dr. HELEN BOYLE believed people, especially children, showed a strong tendency to bury unpleasant memories. In some cases the psycho-analyst succeeded in burying those memories deeper.

Dr. A. N. BOYCOTT spoke of the power of opium in causing dreams.

Dr. R. H. STEEN pointed out that Freud did not refer everything to sex impulse. Freud had shown a wonderful patience and labour, for he had analysed a thousand of his own dreams before putting pen to paper, and 50 of his followers had done the same thing, so there was a great mass of material to go upon. He would have liked to hear a reference to the Zürich school, which went beyond Freud, and held that dreams had a prospective as well as a regressive function. Maeder had written extensively on this.

Dr. MONRAD KROHN said he had never seen the eradication of the sex-complex do any patient any good, yet he could not look upon Freud's ideas with so much indignation as did some others. There had been, in his view, a great heaping-up of new terms, without corresponding enlightenment.

Sir ROBERT ARMSTRONG-JONES replied on the various points raised.

**ERRATUM.**—In the report last week of the debate which took place at the Medical Society of London on Naval Medicine in the Great War, the latter portion of the speech inadvertently attributed to Major Mott was made by Dr. Thomas Beaton.

#### JOURNALS AND MAGAZINES.

**Science Progress** for January.—This excellent quarterly contains articles of the first interest to medical men in several of the departments of special knowledge with which medicine is now seen to be intimately concerned. Dr. Mercier continues a valuable analysis of the facts which form the answer to the old and difficult question—What is a disease? Dr. R. A. Houston, lecturer on physical optics in the University of Glasgow, gives an unmathematical account of a theory of colour vision which has already been described in the Proceedings of the Royal Society, and although the paper is necessarily highly technical, others besides specialists will be able to follow its arguments. Mr. W. P. Pycraft, of the Zoological Department of the British Museum, replies with force to the speculations of Mr. G. S. Miller, of the Smithsonian Institute at Washington, upon the jaw of the Piltdown man, the nature of his criticisms being dictated by the unfortunate fact that Mr. Miller appears not to have seen the remains concerning which he states that the cranial portions are unequivocally human, while the lower jaw is that of a chimpanzee. Mr. Pycraft's whole-hearted desire to demolish Mr. Miller's contentions has received the endorsement of Dr. Smith Woodward, Professor Elliot Smith, Professor Arthur Keith, Professor A. S. Underwood, and Dr. Broom. Useful notes on the recent advances in science are made by a well-qualified group of writers, and the editor, Sir Ronald Ross, contributes an essay-review, entitled "The Sister of

Science," founded on a recent book of verse by Mr. John Masefield and the "Book of Homage to Shakespeare," edited by Dr. Israel Gollancz. The title of the essay-review displays the writer's well-known love of poetry; its contents show that, having given proof of his personal abilities in the field of poetry, he is also a sympathetic critic.

The *Cornhill* for February contains a very interesting note on the sensations of being gassed recorded by Mr. Lewis R. Freeman in an article entitled "Beating Back from Germany." Mr. Freeman, an escaped prisoner from Germany, was among the first victims of the use of gas in war, when no precautions were taken and when the treatment was also still to find.

"My first sensation," he says, "was of a smarting way up inside of my nose. This quickly extended to my throat, and then, as my lungs suddenly seemed filled with red-hot needles, I was seized with a spasm of coughing. Coughing up red-hot needles is not exactly a pleasant operation, and the pain was intense. Mercifully, it was only a few minutes before a sort of stupor seemed to come on, but even as I passed into half-consciousness I was aware of my outraged lungs revolting, in heaves that shook my frame, against the poison that had swamped the trench. With some of my comrades the fighting instinct was the last thing that died, and I have a sort of a recollection of two or three of them clutching at the parapet and firing from cough-shaken shoulders off into the depths of the rolling yellow gas clouds. One lad toppled over beside me and still kept pumping shots from the bottom of the trench. I remember hazily trying to kick his rifle out of his hand as he discharged it over my ear, and, failing to locate it with my foot, recall groping instinctively for my old wrench and trying to disarm him with that. My last recollection of this stage of things was the shock of feeling the wrench-handle swing backwards harmlessly for lack of my two shrapnel-smashed fingers to steady it. I had rolled and writhed, in the agony and pain of the gas in my lungs, in a pool of slush in the bottom of the trench, and it must have been the lying with my face buried in the shoulder of my wet woollen tunic that saved my life."

After describing his recollections of the occupation of the trench by the Germans, he continues:—

My connected recollections begin after my waking up in a hospital—well back from the Front, but still not out of the sound of the guns—that was evidently devoted entirely to "gas" cases. The ward I was in was filled with men from my own regiment, but what interested me specially—as soon as I was able to take any interest in anything beyond my own suffering—was to observe that a great many Germans were also being treated in the same hospital. I never did find out just how these happened to be "gassed," but presume it was either through accidents to their apparatus or from their "snoots" being faulty. At any rate, the Germans had evidently prepared in advance for "gas" cases, and the chances are that they pulled through a good many of us who might have died had we been taken back to our own hospitals, where they had, at that time, small facilities for handling that kind of trouble. The ward was kept as hot as a Turkish bath, and some of our chaps thought this was done with the idea of making our agony worse. One of them, who jumped out of bed, threw up a window, got a lungful of cold air, and died the same night, gave us a proper object-lesson in why the air had to be kept at close to blood heat. Some of them also thought that a kind of stuff they gave us to inhale made us worse rather than better, but that was only their imagination. If there was any real ground for complaint it might have been on the score that the doctors tried a good many experiments on us, because this was the first chance they had had to study gas poisoning on a large scale, but that was no more than we could have expected.

The *Burlington Magazine* for February.—This admirable monthly magazine is publishing a series of notes on dress as described in Shakespeare, which have considerable medical interest, though nothing, probably, was further from the mind of the writer. The medical conclusion will be that our modern attire, although constantly ridiculed as dull and meaningless in detail, and unhygienic in design, is a far more healthy method of dressing than that in use by the Elizabethans. The rich habits of the sixteenth century, save in the case of persons endowed with money and prominent in position, were not hastily discarded. Elizabethan suits, cloaks, breeches, and jerkins went on not only from year to year, but from father to son, and must have been veritable germ-traps by the time that they reached the valet or were cut up to adorn more modest clothes. For even where a garment was not handed on in this way as a whole, its various trimmings of lace, braid, or fur were made to adorn newer garments in a manner which modern thrift or modern ideas of cleanliness would not condone.

# THE LANCET.

LONDON: SATURDAY, FEBRUARY 24, 1917.

## Food Problems.

THE U-boats and Lord DEVONPORT have produced among thinking people in this country a concentration on food problems in much the same way as the publication of the Eltzbacher report did in Germany two years ago. Of this report we were able to publish an extensive summary in THE LANCET of Feb. 20th, 1915. Up to now the average well-bred person in this country has been slightly overfed, and in consequence—a point distinctly in favour of slight overfeeding—has thought little about food, any preoccupation with the subject being left to the glutton and the really hungry. The report drawn up by the Committee of the Royal Society bears comparison with the German figures and shakes many of our preconceived notions. It is surprising to learn that the available food per man before the war occurred was considerably larger in this country than in Germany—4009 large calories in England compared with 3642 in Germany. The idea was certainly prevalent that the German ate more than the Englishman, and this may, of course, have been true or merely an impression gained from a difference in table manners. But, if true, it is, at all events, nearly certain that we had more food at disposal, and if we did not eat it we must have thrown it away. There is, as the Royal Society report points out, a small unknown factor in that the English calories are calculated on the total amount of available foodstuff, whereas the German figure takes into account the deduction for food which is eaten but not utilised in the bodily economy. If this deduction amounted, as appears, to about 11 per cent. the figures for the two countries become more nearly equal. There are, of course, various ways of throwing away food. It may be destroyed or spoiled before it reaches the consumer, squandered by careless housekeeping or improper culinary methods, wasted by complete ignorance of the methods of carving, or left on the plate; and doubtless all these ways are physiologically more righteous than burdening the digestive and excretory organs, yet some or all, with varying intensity, are still playing their part in many homes.

Starting, then, as we may, from 4000 calories as about the normal adult allowance of food in each country, we note that in 1916 the British soldier on active service abroad is apportioned 4644 calories, at home a sixth less, or 4031 calories, in each case including extras, leaving an estimated 3859 calories available for the civilian. The Eltzbacher Commission calculated that 3151 calories per head would be available in Germany in 1916 if certain measures of increased production and economy were carried out. The actual physiological requirement of the

adult has been placed in the neighbourhood of 3000 calories by German authorities and of 3500 calories, for a man on fairly light munition work, by Dr. LEONARD HILL. But we really do not yet know by experiment on any large scale the food requirement of a large mixed body of persons in order to maintain health, and even the chairman of the Royal Society's Committee in investigating last week his own unrestricted diet as a brain-worker was surprised to find the result work out so low. A slight clue to the calorie value now considered necessary in Germany may perhaps be gained from KÖHLER's recent suggestion to issue cards entitling the possessor to buy food up to 2500 calories per head per day, with some extras for a man engaged in severe manual work. For the sake of the revenue KÖHLER would allow the purchase of more calories than this, at the price of a rapidly ascending increment tax. For the rest a careful study of German medical literature fails to convey any certain impression that the food restriction has so far worked harmfully on the adult. Medical Munich, in fact, allows itself the playful suggestion that the restriction has not been without advantage to the slightly over-nourished Berlinite.

When we turn to the quality of foodstuffs we find that war conditions are giving the man in the street some much-needed insight into the distinction between economical and expensive foods. The Royal Society's Committee brings out the relative cheapness of dairy products over beef and mutton, especially over the former. The report states that 1000 calories in the form of milk from a good cow presuppose only 3 lb. of starch or its equivalent in the fodder supplied, whereas the same number of calories of steer beef are the product of 9 lb. of fodder. Similarly, a substitution of cheese for butter would give an average of 4·2 grammes more protein per man throughout the whole country. In agricultural countries dairy products, pig-meat, and veal are the natural food of the people, and we now realise that economy, as much as homely taste, may dictate the preference for these meats. That a whole nation may rapidly change its diet-sheet is evident from the fact that Germany ceased at the onset of war to export its million tons of beet sugar and consumed them at home to compensate for the loss of imported fats. The Eltzbacher Commission pointed at the time to England, and a fortiori America, as countries in which a high consumption per head of sugar was unattended by ill-result. The non-necessity of a large proportion of meat in the dietary was strongly emphasised by the Commission, and in Charlottenburg any citizen may now exchange his full meat-card of 250 grammes for 375 grammes of macaroni, semolina, or oatmeal, or a child may exchange his meat-card of 125 grammes for 200 grammes of cereals. RUNGE has just noted the greatly diminished incidence of eclampsia among pregnant women in Berlin, and puts this down to the larger proportion of fat and carbohydrate and the smaller proportion of protein in their daily food.

The distribution of the total food among the various age-groups of our population affords fruitful material for useful discussion. The Royal Society's

Committee and the Eltzbacher Commission agreed in allotting to the young child two-fifths, to the child of 6 to 9 one-half, and to the lad or girl of 14 or 15 three-quarters of the man's ration, assessing the adult woman at four-fifths. For the soldier in the trenches, being a man in the prime of life, with well-conditioned muscles and arteries, exposed to cold, fatigue, and prolonged bouts of severe exertion, it is probably difficult for any amount of overfeeding to be actually harmful. Sir ALFRED KEOGH called attention last week to the value of this relative excess of food in the prevention of infections under conditions of war. Overfeeding, too, in phthisis, has been credited with a certain value, and there have been painful reports in circulation of the incidence of tuberculosis among the now chronically underfed children in Belgium. But an Army food ration of 4500 calories, associated with some rum and much tobacco, would infallibly have most harmful effects on a pure brain worker, as well as on the older man whose excretory powers are diminishing and whose arteries are hardening. And after the age of 45 there is no reason to suppose that an excessive ration of food protects the civilian at all events against infections, and much reason to know that it shortens his life from gout and arterial degeneration. HERMANN SAHLI indeed tells his students year by year that they have a certain amount of food which they can consume in the course of their lives, and that they can do so as they please, whether slowly or quickly, living in the one case to a great age, and in the other dying early as a result of high arterial tension. Commissions in Australia and America have recently<sup>1</sup> called attention to these dangers. In the woman after the climacteric there is a tendency either to become stout or thin, and little doubt can be felt that the latter tends toward comfort and longevity. The food limitation in Germany has, however, led to much anxiety in regard to the children, and the results of a few investigations bearing on the subject have been published. SCHLESINGER has just reported on 1300 school children in Strassburg, of ages from 6 to 14, weighed at the beginning and end of the third quarter of 1916. Normally during this school quarter 75 per cent. of the children lose weight, but last year 90 per cent. of them did so, including those from well-to-do families. Loss of fat was evident, but in spite of this not more than the usual proportion of anaemia was noted, and no evidence of the listlessness and inertia of malnutrition. The author's recommendation was, nevertheless, to increase the bread ration for children of 14 to 17 and to give a morning glass of milk to those of 6 to 10. H. FINKELSTEIN admits the feeding of the young child in poor Berlin families to be a matter of grave difficulty, incidentally mentioning that the poor mother's midday meal consists now usually of potatoes and swedes, while the daily ration of sugar is at present 25 grammes and of potatoes 360 grammes.

The net conclusion to which it is possible to come from the various conditions set out above is as

follows. In any community with an available food-supply of anything like 3500 calories it should be possible so to apportion it among the various age-groups that neither the young child and nursing mother nor the active young adult suffers. Outside these groups a greater limitation of intake may be tolerable or even beneficial.

### War Injuries and Neuroses of the Ear.

IN addition to direct trauma of the hearing organ and to the damage produced upon it by long-continued exposure to loud noises, the present war has made us acquainted with new varieties of deafness as a result of the tremendous shocks to which the delicate nerve structures of the cochlea and brain are so frequently exposed. The most distressing of these nerve injuries are seen in soldiers who have been buried by explosions, an experience which, apart from any obvious bodily injury, frequently brings about a complete functional disorganisation of the whole nervous system. In the worst cases death is the result. But, short of that, the man may be reduced to a state of imbecility, with vertigo, blindness, deafness, and loss of speech. This condition of general sense-paralysis is, however, only transitory. In the course of a few hours the patient recovers control of his faculties, and has little to show for his terrible experience save a painful and obstinate "loss of nerve." In many instances, however, we must add, one or other of the special senses or faculties remains out of gear for several weeks or months. And one of the senses thus afflicted is frequently that of hearing.

At a special discussion on "War Injuries and Neuroses of Otological Interest," held at the Otological Section of the Royal Society of Medicine on Feb. 16th, these points were fully brought out by the speakers, all of whom had had special experience of these particular types of warfare injury. As we might expect, the differentiation between the functional or temporary upset and the organic or permanent lesion is of great importance, and sometimes of considerable difficulty. For this distinction many speakers laid stress upon the general aspect of the patient as affording a clue to the real nature of the deafness. Another point of value is that the functional or "psychic" deafness is bilateral and, at first, absolute, while deafness from a permanent lesion is asymmetrical and incomplete. The latter type has become familiar to the otologist nowadays as a sequel to a superficial bullet wound of the skull in the neighbourhood of one or other ear. But a shell explosion may also, of course, produce a labyrinth lesion which leads to permanent deafness and that without any evident traumatism. A third method of differentiation consists in the use of the vestibular tests which in functional deafness give a normal or exaggerated response, while in organic perceptive deafness the vestibular reflexes are more or less impaired. At the outset, the participation of the vestibular system in the general disturbance is evident in the presence of vertigo and spontaneous nystagmus

<sup>1</sup> A Campaign against Adult Mortality, THE LANCET, 1916, II., 683.

immediately after the explosion. But, as in other sudden interferences with the entire labyrinth, the vestibular system recovers early, so that by the time the patient reaches the base hospital his acute vestibular phenomena have usually subsided. The prognosis in functional deafness is good even when it is absolute; recovery, and sometimes sudden recovery, is to be expected. The latter event may be brought about by judicious "shock" treatment, such as is brought about by running cold water into the external meatus, or by applying the caloric test, a method of treating hysterical deafness which was introduced some years before the war. The shock treatment by faradism, it should be noted, is harmful and should be avoided. When the deafness persists the treatment adopted is, first and foremost, the building up of the patient's bodily and mental strength by good food, fresh air, bright society, and, above all, peaceful surroundings. If, in spite of these favourable conditions, the deafness continues, then the most reliable method of restoring function is by some method of re-educating the hearing. This may be done, first of all, by the careful and persistent application of vibrating tuning-forks to the mastoid so as to arouse the sleeping sense through the medium of bone-conduction. Later on recourse may be had to resonators. Several curious facts emerged in the course of the discussion, which was well maintained, one being that when the tympanic membrane is ruptured by the shell-burst the labyrinth manifests no evidence of damage. This experience is in correspondence with the fact that shell-shock in general is rarely associated with actual external wounds. But it is certainly remarkable that the rupture of a small structure like the tympanic membrane should be sufficient to divert the weighty blow from the more important cochlea. Doubtless the cause of this phenomenon lies in the fact that the energy of the explosion-wave in the act of destroying the integrity of the membrane is thereby dissipated in a series of deviations from the normal path. And so the delicate internal ear escapes the injury.

Mr. H. J. MARRIAGE, the President of the Section, in his introductory paper advocated for the protection of the hearing the use of an obturator in the external auditory meatus of the soldier exposed to a bombardment. And the same, of course, applies to the sailor. But he warns us that the obturator should be made of plasticine or some such material, and *never of celluloid*, as several men have had their ears damaged by the flash of a shell igniting plugs made of that inflammable substance.

AN Order has been issued by the Local Government Board authorising medical officers of health to vaccinate or revaccinate small-pox contacts gratis where the circumstances demand it.

A READING of the poems of Sir Ronald Ross will be given on March 23rd, when the vocal interpretation will be undertaken by Miss Miriam Lewes and Mr. William Stack. Sir William Lever has placed his Hampstead house at the disposal of the Poetry Society for the occasion, and non-members of that society may obtain further details from the secretary at 16, Featherstone-buildings, W.C.

## Annotations.

"*Ne quid nimis.*"

### CRIMINAL LAW AMENDMENT.

THE new Criminal Law Amendment Bill introduced in the House of Commons by the Home Secretary contains very important provisions not only relating to the communication of venereal disease, although these constitute the most novel feature of the proposed legislation. By Clause 2 of the Bill it is made penal for a person suffering from venereal disease in a communicable form to have sexual intercourse with any other person, or to solicit or invite any other person to have such sexual intercourse, the maximum penalty provided being two years' imprisonment with hard labour. It will, however, be a defence if the person charged proves that he or she had reasonable grounds to believe that he or she was free from venereal disease when the alleged offence was committed. Power is given to the court to order the medical examination of the person charged in certain circumstances, and the examination thus ordered shall, in the case of a female, if she desires it, be conducted by a female doctor. It is further provided that—

Where a person has within three months before the commission of any alleged offence under this section received a written notice either on an examination ordered under this section, or while under compulsory detention in any prison or other institution, from a duly qualified medical practitioner that he or she is suffering from venereal disease in a communicable form, that person shall be deemed to have been so suffering at the time when the alleged offence was committed, unless the contrary is proved.

As the fact that any person was at a given time suffering from venereal disease in a communicable form must in most instances be only provable by medical evidence, the importance of the proposed law to the medical profession is obvious. Further, a question in this connexion may well suggest itself as to how far pressure is likely to be brought upon medical practitioners to give evidence against their patients in order to obtain their conviction, and the insertion of words protecting them against the possibility of such pressure is desirable. The conferring of privilege upon any communication, made by a medical man on the subject of infection in the public interest, is a further useful addition to the Bill. The Bill also makes very important alterations in the law relating to indecent advertisements. These, it will be remembered, have hitherto been dealt with under an Act passed in 1889 which provided penalties for classes of advertisements the prevention of which is badly wanted, but only when they appear in public places. Under the Bill, which, no doubt, the Government will have no difficulty in passing, any "person who publishes by way of advertisement or causes to be so published any picture or printed or written matter which is of an indecent or obscene nature" will be guilty of an offence, and not only any advertisement relating to venereal disease and cognate matters is declared to be indecent, but also any which suggests "directly or indirectly the use or taking of any appliance, drug, substance, or thing for the purpose of procuring miscarriage or abortion, or which suggests directly or indirectly that any premises are or can be used for immoral purposes." Advertisements in bona fide medical and pharmaceutical publications

are made exceptions to the above. The general prohibition of the advertisements of quacks and nostrum vendors who, by their obvious admissions, are abortionists is a matter in which THE LANCET has interested itself for many years. Such advertisements have recently been confined to a few disreputable publications, some of which seem to have disappeared since the war began. They were wont to make flaunting appearance in all sorts of prints—especially in newspapers published on Sunday and in religious papers. In any case, the proposed Act of Parliament will deal a vital blow to those advertisers of the sort who survive and to the iniquitous trade which they have fostered and assisted. The Criminal Law Amendment Bill further proposes to render more stringent the provisions of the law relating to sexual intercourse and acts of indecency in the case of girls under 16 years of age, and to the keeping of brothels.

#### SPECIFICITY IN ANTISEPTICS.

THAT the power of an antiseptic to kill organisms is not the same for all organisms has been recognised in bacteriological practice for a long time, and Dr. Kenneth Taylor's special study in regard to the antiseptic treatment of chronic infected wounds, exhibiting, as they do, several types of bacteria, deserves careful reading. He records a large number of bacteriological examinations of wounds under treatment with different solutions, and instances are brought forward of the specific action of certain dressing solutions. The belief is expressed that further analytical study of antiseptics will result in the discovery of dressings specific for one or more groups of bacteria. By a successive application of these dressings the organisms present in a wound, he holds, may be reduced in number or eliminated, one variety at a time, and true sterilisation of a suppurating wound accomplished. The concept of the "general antiseptic," he concludes, must go by the board and the search for a cure-all be recognised as unprofitable. One interesting case is that of the gas bacillus, on which no effect seems to have been produced by any of the dressing solutions with the exception of quinine, where the early disappearance of the organism was strikingly apparent, a result which is consistent with earlier experience of the behaviour of this alkaloid both *in vitro* and in clinical application.<sup>1</sup> Quinine, however, showed very little action upon the staphylococcus and still less upon the *B. pyocyanus*. Further examples of equal interest of the specificity of antiseptics are given with other germicidal preparations. Thus, carbolic and cresol proved more active against the streptococcus than against the staphylococcus, and showed very little activity against the gas bacillus. Thymol showed a fair degree of activity against the streptococcus, but was less active against the staphylococcus and still less so against the gas bacillus, while it showed practically no action upon *pyocyanus*. Dakin's solution, which has been regarded as a general antiseptic, showed a moderate activity against the staphylococcus, but was nearly inert against the *B. pyocyanus* and the gas bacillus, although more active against the streptococcus. The results are certainly full of interest and importance and seem plainly to point out the great variation in the activity of some of the "general antiseptics" toward the common bacteria of infected wounds.

so that the conclusion that bactericidal values are relatively specific and not general seems abundantly justified. Touching somewhat upon the same subject, a paper on "A Comparison of Some Antiseptics in Respect to their Diffusibility, Action of Leucocytes, and Action on Ferment Activity," by Hugh E. Magee, B.Sc., appears in the February number of the *Edinburgh Medical Journal*, in which the author expresses his acknowledgment to Dr. Kenneth Taylor for his help in the prosecution of this research. In order to demonstrate wherein antiseptic solutions differ from each other, a comparative study was made of some of the common bactericidal agents in regard to diffusibility, chemiotactic action, and action on ferment activity. These properties are shared in different degrees by various germicidal solutions as is clearly shown in the paper, and the results are instructive in connexion with the treatment of wound infection. A number of antiseptics were chosen for the investigation and their values in the directions indicated deduced. The specificity of the antiseptics tested bears a relationship to the properties investigated.

#### THE STATISTICS OF INFANTILE MORTALITY.

TUESDAY'S lecture at the Royal Statistical Society on "The Relation of Infantile Mortality to Mortality in Subsequent Life" was delivered by Dr. John Brownlee, director of statistics to the Medical Research Committee, and will serve as a useful tonic to all those who have to deal with the statistics of infantile mortality. He began by describing the three points of view taken in regard to the attempt to save infant life by means of administrative action. The first group holds strongly that every child's life saved adds another potentially fit member to the working power of the State. The second is an opposing group which holds equally strongly that measures such as those taken to save infantile life can only lead to an increase in the number of unfit persons for whom the nation has ultimately to provide. The third group, in which the lecturer found the medical officers of health strongly represented, regards the unfitness which develops after infancy as largely due to the environmental conditions in which the child grows up. Dr. Brownlee then examined the statistical evidence on which these points of view were based, and found reason to doubt every method proposed to measure the influence of the death-rate as a selective agent. A large number of deaths among children are due to epidemics, and so long as our knowledge of the epidemiology of disease remains as limited as it now is no estimate of selective influence can, he said, be of the least value. This agnostic attitude does not prevent Dr. Brownlee being personally of the opinion that an improved environment is the most important measure for the maintenance of a healthy race, and that no effort can be too great to accomplish this improvement.

#### FERNS AS A SOURCE OF STARCH.

Professor A. E. Shipley's suggestion in a letter in the *Times* of Feb. 19th that the underground stems of the common bracken fern or brake might profitably be used as a source of starch deserves attention. The common bracken fern is abundant enough throughout the country, but, of course, one serious difficulty would be its economic collection. The underground stem, says Professor Shipley, is

<sup>1</sup> Use of Quinine in the Treatment of Experimental Gaseous Gangrene, THE LANCET, Sept. 4th, 1915, p. 538; and the Use of Quinine Hydrochloride Solution as a Dressing for Infected Wounds, Brit. Med. Jour., Dec. 25th, 1915.

packed with starch, and is simply there asking to be taken. It would be interesting to find out the actual percentage of starch which the rhizome contains, but in the references which we have been able to make there is no information upon this point. According to Dr. W. T. Fernie in his book on "Herbal Simples," the bracken contains much potash, and its ashes were at one time employed as the alkali for making soap. The young tops of the plant, he goes on to say, are boiled in Hampshire for hog's food, and the peculiar flavour of Hampshire bacon has been attributed to this custom. It would appear from this authority also that the root affords much starch, and in northern climates a coarse kind of bread is made from the roots of the brake fern, whilst in the south the young shoots are often sold in bundles as a salad. All this confirms Professor Shipley's observations. In an article on "Ferns" in "The National Standard Dispensatory" it is stated that "in the East Indies and Polynesia the rhizomes of a number of ferns are eaten as starchy foods, or the starch is extracted from them." Experiments might be begun to ascertain the most economical method of separating the starch from the rhizome, and then some idea will be gained as to whether the yield of farina is profitable. At any rate, the starch so obtained might be used in certain industrial processes in which starch from cereals is used, and the latter so saved for food purposes.

#### THE PREVALENCE OF INTESTINAL PROTOZOA.

A SURVEY of the special report recently issued by the Medical Research Committee on "Amœbic Dysentery and the Protozoological Investigation of Cases and Carriers" contributed by Mr. Clifford Dobell will bring to the medical world the knowledge of the great prevalence of amœbic dysentery carriers amongst our forces, a prevalence which is borne out for the Salonika area by the paper of Lieutenant W. Roche, R.A.M.C., which appears in another column. Mr. Dobell's first conclusion, which he has formed as a result of his investigations, is as follows: That negative findings of *Entamœba histolytica* cysts in examinations of the faeces, even when carried out by competent examiners, cannot always be relied on to prove that the patient is not a carrier of the disease. He deduces from detailed observations that all cases that have not been treated should have at least six different examinations of the stools before being declared negative. Cases undergoing treatment should not be declared negative on examinations made during this time, as a negative phase is then very prevalent, but they should be examined at intervals during the three weeks following the completion of treatment. The second conclusion formed by Mr. Dobell is that emetine bismuthous iodide, properly administered in full doses, frees carriers from *Entamœba histolytica* cysts, whilst treatment with emetine hydrochloride has not been found successful. Emetine bismuthous iodide is a new drug introduced by Dr. H. H. Dale.<sup>1</sup> The earlier forms prescribed caused considerable nausea and vomiting, but in more recent preparations this defect seems to have been greatly lessened if not overcome. Mr. Dobell deals also in the report with the intestinal flagellate protozoa. He does not see any reason to consider them pathogenic, and thinks they generally occur as

part of a diarrhoea and are not the cause of one. This is the general opinion amongst the greater number of French and English workers. No one has yet found any remedy which completely eliminates these parasites from the infected intestine.

#### OPHTHALMIA NEONATORUM.

THE second annual report just presented by the Central Council for District Nursing in London to the annual meeting deals chiefly with the subject of ophthalmia neonatorum. 806 cases were notified in 1915 to the London County Council, being 60 more than the average for the last few years, and several constituent nursing associations have recently reported an increase in the number of cases seen by them. The Council considers that much of the difficulty in dealing successfully with the condition arises from the fact that, at the time when the disease usually appears, both mother and infant require skilled care and treatment. Two main alternative lines of procedure are open for adoption: (1) The removal of both mother and babe in an ambulance to undergo appropriate treatment in hospital or infirmary; (2) adequate supervision and treatment at home. The Council discusses these two alternatives without definitely pronouncing its own preference in the matter. While recommending, on the one hand, to King Edward's Hospital Fund the provision of greater facilities for in-patient treatment, it lays stress also on the need for some training in ophthalmic nursing on the part of district nurses, and petitions the Local Government Board to give grants to nursing associations for service rendered in cases of ophthalmia. The in-patient treatment of these cases has, we believe, long been attended with excellent results at the St. Paul's Eye Hospital in Liverpool, and probably both alternatives may have their place in any well-ordered scheme for the metropolis.

#### THE USE OF ANTIMONY.

FEW drugs have a record of a more varied reputation than antimony, ranging from the extravagant praises of Basil Valentine 300 years ago to the comparative neglect of more recent times. The history of its use was lately traced in a paper read before the Hunterian Society.<sup>1</sup> A favourite remedy for many diseases in the seventeenth and eighteenth centuries, it was later adopted in the place of blood-letting for pneumonia and inflammations generally. This became the orthodox treatment for 50 years. Rousseau, whose lectures were published in 1861, was probably the last great champion of antimony in pneumonia. By that time it had been discovered that inflammations recovered better without either antimony or venesection. The doctrine, however, survives in some medical minds. The recent revival of the use of antimony is one of the triumphs of rational therapeutics, for it was through reasoning from its chemical affinities that Professor Cushny and Mr. Plimmer were led to try the remedy in diseases dependent on protozoal parasites. The control of trypanosomiasis by antimony and arsenic, given together or in alternation, is as striking in its way as the cure of malaria by quinine. The respective values of the two metals and the best method of administration have yet to be fully worked out. At present the drugs are

<sup>1</sup> THE LANCET, 1916, II., 183.

<sup>1</sup> THE LANCET, 1916, II., 1104.

often given intravenously at the beginning of the treatment, and later intramuscularly or by the mouth for a period of two years or more. Owing to the irritant and depressing qualities of many of the salts of antimony it is very necessary to use the metal in a form most easily tolerated. Several efforts have therefore been put forth to obtain a colloidal solution. The method of preparation of a stable solution of this nature was recently described in our columns by Dr. U. N. Brahmachari, of the Campbell Medical School, Calcutta.<sup>2</sup> The effects of antimony in sleeping sickness and kala-azar have led to its trial, with apparently good results, in the allied spirochaetal diseases syphilis and yaws—in the first of these in the form of antiluetin.<sup>3</sup> Here the old reputation of Plummer's pill, containing antimony sulphide, given as a so-called alterative, may be recalled. Some of the cases in which it seemed to do good may well have been those of chronic spirochaetal infection. The value of tartar emetic in some skin affections, as shown by Crocker and Willmott Evans, may have a like explanation. It may be noted that antimony is a constituent of many natural arsenical waters, especially those of Bagnères de Bigorre and Dax in the Pyrenean district.

WE regret to record the death last Saturday of Dr. Louisa Woodcock, physician to the Endell-street Military Hospital and out-patient physician to the New Hospital for Women.

NEXT week, at the Royal College of Surgeons of England, Dr. Wilfred Harris is to deliver two Arris and Gale lectures on "The Morphology of the Brachial Plexus in its Relation to Surgery" (Monday, Feb. 26th, and Wednesday, Feb. 28th, at 5 P.M.), and in the following week Professor A. E. Webb-Johnson will give a Hunterian lecture on "The Surgical Complications of Typhoid and Paratyphoid Fevers" (Monday, March 5th, at 5 P.M.).

OUR list of New Year Honours published last week should have included the name of Mr. Charles Lane Sansom, Principal Medical Officer, Federated Malay States, who has been made a C.M.G. In a supplementary list is the name of Professor J. C. Bose, C.S.I., C.I.E., who has received a Knighthood. His investigations into the electrical response of muscular and plant tissues are well known, as are also his studies in regard to the action of drugs on plants. An abstract of a lecture by Professor Bose on this latter subject was published in our issue of Nov. 7th, 1914, p. 1105.

<sup>2</sup> THE LANCET, 1916, II., 728.

<sup>3</sup> Suzuki: Deutsche med. Wochenschrift, 1913, p. 985.

## THE LANCET, VOL. II., 1916: THE INDEX.

OWING to the continued shortage in the paper-supply the Index and Title-page to the volume of THE LANCET which was completed with the issue of Dec. 30th, 1916, have been printed separately, and copies have been supplied gratis to those subscribers who have intimated to us their wish to receive them. Other subscribers will be similarly supplied, so long as the stock remains unexhausted, on application to the Manager, THE LANCET Office, 423, Strand, London, W.C. Such applications should be sent in at once.

## THE CONTROL OF VENEREAL DISEASES.

### Early Preventive Treatment.

A CORRESPONDENT has supplied us with these notes on the history of early preventive treatment of venereal disease.

The first experiments seem to have been made by Metchnikoff, who reached the conclusion that an ointment containing not less than 25 per cent. of calomel applied a few hours after exposure to syphilitic infection stopped the development of the disease. An ointment of lesser strength than 25 per cent. of calomel proved ineffectual. The ointment he found best contained 33 parts of calomel, 67 parts of lanoline, and 10 parts of vaseline, and this, with slight modifications, seems to have been employed by all who have subsequently attempted early preventive treatment. For the prevention of gonorrhœa urethral injections of various antiseptics have also been tried, of which 2 per cent. protargol has received the most favour. In 1904 preventive treatment was instituted in the Austrian Army, in 1907 in the French Army, and in other continental armées at about the same time. In the Navy and Army of the United States the method began to be used about 1909, and in the *Military Surgeon* of that year is an account of the issue to soldiers in a dépôt in the Philippines of a "prophylactic kit," but no definite figures are given to show the results. Several sets of figures are, however, available to show the success of preventive treatment at various naval and military stations in the United States.

At Jefferson Barracks, Missouri, a military recruiting dépôt, compulsory preventive treatment was instituted in August, 1911. It was tried first in one company and proved so far superior to voluntary measures that it was extended in September, 1911, to the entire command. On Jan. 1st, 1912, the dépôt commander issued a memorandum to the troops on the subject of venereal diseases and their prevention. "Experience has shown," he says in the course of this memorandum, "that 95 per cent. of cases of venereal disease are preventable if treatment is given a few hours after sexual intercourse." Then follow orders, among them this:—

All enlisted men of the command who expose themselves to the danger of contracting venereal disease ..... will immediately upon return to the Post ..... report at the hospital for preventive treatment. Enlisted men absent from the Post on pass will upon their return and before turning in their passes endorse on the back thereof over their initials whether or not they were exposed to venereal infection during their absence from quarters.

Penalties were attached for non-compliance with these orders.

The results in this dépôt are stated as follows: In 1910 the admission rate for venereal disease was 313 per 1000. At this time no inspections were made to discover concealed cases and it is therefore probable that the full number of cases which occurred would give a higher figure. In July, 1911, monthly venereal inspections were begun, so that from this date onwards the admission rate represents the total number of cases, and would almost certainly be higher than hitherto, were preventive treatment ineffective. In September preventive treatment was made compulsory. The admission rate for the whole of 1911 was 250 per 1000, showing a fall of 20 per cent. since 1910. The rate for the last four months alone was 166—scarcely more than half that for 1910, and of these last cases more than 50 per cent. had contracted the disease before enlistment.

The figures for the first six months after prophylaxis was instituted are as follows:—

September, 1911, to February, 1912.

Total venereal admissions.	Old cases (contracted before enlistment, before arrival, or recurrences)	New cases (total).	New cases who had reported for prophylaxis.	New cases who had not reported for prophylaxis	Total prophylactic treatments given.
117	74	43	15	28	1675

Thus of 1675 individual preventive treatments only 15, or 0·84 per cent., proved ineffective.

Similar results are recorded from Fort Washington by Captain Mahlon Ashford of the U.S. Army Medical Corps. He tabulates the results of five months' compulsory prophylaxis as follows.

The number of hours elapsing between exposure to infection and prophylactic treatment as recorded in Column 3 rests necessarily on the soldiers' own statements, and is almost certainly in some cases an under-statement. As this interval is

Month.	Number of prophylactic treatments.	Number of infections after treatment.	Number of hours between exposure and treatment.	Percentage of infections.
Dec., 1913	40	1	5·3	2·5
Jan., 1914	34	3	5·6	5·5
Feb., ..	40	1	5·1	2·5
March, ..	57	0	6·4	0·0
April, ..	50	1	3·8	2·0
5 months' total... }	221	6	Avg. 5·2	Avg. 2·7

of first-rate importance an element of fallacy is present in these statistics. But it is a fallacy which, if corrected, could only make them more convincing, and the results as they stand are good. Of 221 men applying for treatment only 6 developed disease—4 cases of gonorrhœa, 2 of syphilis. Good results are also recorded from the U.S.A. naval hospital at Cavite. Here before prophylaxis was instituted venereal disease accounted for 25–30 per cent. of all admissions. After its institution cases of gonorrhœa fell from a 20–25 per cent. average down to 8 per cent., including in one year 30 cases not protected. Chancroid fell similarly from 2–3 per cent. down to 2 per cent., including 10 cases not protected. Syphilis fell from 20 cases a year down to 1 case, not protected.

All the results so far mentioned appear so good that it is surprising to find the statistics for the whole U.S. Navy unfavourable rather than favourable. These figures, taken from the reports of the Surgeon-General of the U.S. Navy, and covering a total period of 12 years, are set forth by Surgeon R. C. Holcomb, U.S. Navy, as demonstrating that the system has proved a failure. Two periods of six years are considered, one from 1903–08, before prophylaxis was instituted, and one from 1909–14, after it was made nominally compulsory throughout the Navy.

The admission-rates per 1000 for venereal diseases were as follows :—

—	Gonorrhœa.	Chancroid.	Syphilis.
1903–1908 ... ...	47·23	13·12	22·03
1909–1914 ... ...	91·91	33·18	23·37

The apparent enormous increase in gonorrhœa and chancroid is largely discounted by the consideration that in 1909 it was ordered that all cases of venereal disease should be admitted for one day to hospital for inspection, and the figures after that date therefore include all cases such as were formerly treated outside hospital. But when all possible deduction is made on this count the figures cannot be made to show any improvement following the institution of preventive treatment. The "damage rate" representing the number of days' work lost owing to venereal disease gives no better results even when corrected for the fallacy stated above. A slight improvement in the figures for syphilis seems amply accounted for by the introduction of salvarsan.

The results so far stated are thus contradictory, showing a very definite success in several military and naval depôts on a comparatively small scale and an equally definite failure in the U.S. Navy over a period of years. This contradiction points to the existence of some factor or factors making for failure in the application of the method in the Navy. The failure can hardly be inherent in the method itself or it could not succeed as it has succeeded both in the laboratory and at military depôts.

Two more sets of figures quoted by Holcomb throw some light on what these factors are. The first set shows the extreme importance of every hour allowed to elapse between exposure to infection and the application of prophylactic treatment.

Thus of 1385 exposures treated within the first 8 hours 19 developed disease, a percentage of 1·37.

Of 74 exposures treated between the eighth and twelfth hours 25 developed disease, a percentage of 33·7.

Of 927 exposures treated between the twelfth and twenty-fourth hours 47 developed disease, a percentage of 5·1.

It may be supposed that in any ship where discipline in this matter was not rigid or where the medical officer was not sufficiently alert a number of men must have received their treatment too late. That this was almost certainly the case is borne out by another set of figures showing, besides the apparent ineffectiveness of the treatment, how large a number of men failed to report for prophylaxis, although nominally compelled to do so. 1338 men were given between them 32,791 "liberties" on shore in the course of 15 months. In this period 3268 preventive treatments were given. Among these men in the 15 months there occurred :—

140 cases of gonorrhœa, 77 of whom had not applied for treatment.

61 cases of chancroid, 26 of whom had not applied for treatment.

15 cases of syphilis, 12 of whom had not applied for treatment.

Thus within 15 months 115 out of 1338 men avoided prophylaxis after exposure and developed venereal disease. This does not indicate a high state of discipline in the matter, and suggests that the treatment may have been carried out carelessly and in a manner distasteful to the men. It must also be remembered that the figures for the whole Navy include not only cases which have avoided preventive treatment, but also some who had already become infected before entering the service. In the U.S. Army it is officially stated that 17 per cent. of recruits are syphilitics at the time of enlistment. The percentage of Navy recruits may be lower, but is probably appreciable, and inspection may well have become more careful since 1908.

It seems fair to conclude that early preventive treatment is a successful method of combating venereal disease subject to the conditions that the treatment is made acceptable to the men and is actually compulsory, and that it is carried out within a very few hours after exposure to infection. Our correspondent suggests that the naval and military authorities in this country would do well to consider the publication of any statistics in their possession bearing on the subject for the guidance of the civilian administrative bodies which are now giving earnest attention to the control of venereal diseases.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *The Work of the Service de Santé in the Eastern Campaign.*

M. Picqué recently dealt with the work of the Service de Santé in the Near East at a meeting of the Academy of Medicine. In the Dardanelles campaign he said that the doctors had to grapple with unheard-of difficulties owing to persistent bombardment by the enemy of the sanitary posts. Doctors and attendants were killed or wounded while at work, and it was necessary to remove the greater number of the wounded to the hospital ships. One field hospital had, nevertheless, dealt with 8500 wounded men, on whom 470 operations were performed. M. Picqué illustrated the very grave difficulties in the transport of wounded from trench to field hospital and on to hospital ship, a service of which he was himself in special charge. He made quite clear the real utility of aid-posts, on which rather too much doubt has been cast by the surgeons, and deduced the necessity of stationing at them experienced surgeons to arrest haemorrhage and ensure asepsis. In Macedonia the Service de Santé had also encountered grave difficulties. M. Picqué paid a tribute to General Sarrail, for, owing to his co-operation and that of M. Ricotti, chief of the service, the base hospitals alone are in possession of 20,000 beds. The surgical practice is distributed over 9 hospitals, of which 7 are temporary ones, all comfortable, some excellently well equipped, and challenging comparison with similar installations in Paris itself.

### *Aural Mischief Among Aviators.*

At the Paris Society of Medicine Dr. André Castex stated recently that a large proportion of aviators are among the men presenting themselves at the oto-rhino-laryngological consultations of the Military Hospital Villemin in Paris. From a series of observations it appears that on rising to an altitude approaching 1500 metres all the upper respiratory tract (pharynx, nasal passages, and, above all, the ears) become congested. The aviator relieves his discomfort by breathing through the mouth and practising Valsalva's

experiment. At about 4000 metres his troubles disappear, to return on the descent. On landing deafness is present, lasting sometimes a considerable time, and now and then he bleeds from the ears. These disturbances are, of course, due to the variations of atmospheric pressure. As the aviator rises the external pressure is less than that within the tympanum, Eustachian tube, and, possibly, blood-vessels. On the descent this is reversed. His troubles are accentuated if the aviator has some degree of oto-sclerosis or any malformation of the nasal passages, or if he travels in a noisy machine. A little deafness does not prevent a man from being an excellent aviator, but in rising it is a useful precaution to practise Valsalva's and in descending Toynbee's method. Complete rest for a quarter or half an hour is useful upon landing. Persistent aural trouble yields to rest prolonged over a month.

#### *Industrial Accidents and War Wounds.*

For slight accidents to operatives engaged in controlled factories the military doctors have hitherto granted seven days' leave for convalescence, following the practice applicable to soldiers wounded at the front. The Under Secretary of State for the Military Service de Santé has recently directed a circular to the local directors of the service, informing them that this procedure is inadmissible. The origin of the wounds is not the same. The wounded soldier is in need of rest and of the moral comfort which a home visit will give him, but the mobilised operative is not subject to the same fatigues and dangers, and as a rule already lives at home. An accident during work implies half-pay at the expense of the employer. The injured operative should therefore resume work as soon as he is restored, since the national defence demands intensified production.

#### *The Prophylaxis of Wound Infections.*

Professor Vincent has made a communication on bacterial prophylaxis at the Academy of Medicine. While the wounded man, with his emergency dressing applied at the dressing station, is transported to the field hospital a delay of several hours (from four to eight hours on the average, but often much more) occurs during which bacteria can multiply without hindrance. Sometimes this has already occurred within four or five hours, and in this race between sepsis and surgeon the latter may arrive too late. To prevent this rapid multiplication of bacteria M. Vincent lays down rules of true surgical prophylaxis comparable to those applied to infectious diseases. The surgical future of the wounded man often depends on his first dressing. M. Vincent proposes, therefore, that the wounds should be carefully dredged with a powder composed of 10 parts of hypochlorite of calcium and 90 parts of dry crystallised boric acid. All ramifications are carefully filled up with this powder. For wounds requiring drainage the antiseptic is insufflated into their depths. The application is very simple and produces no pain. A dry dressing of this kind brings the wounded man to the operating table in practically the condition he was in when struck down in the firing line.

#### *Unshapely Noses Corrected Surgically without Scar.*

M. Julien Bourguet reports success in correcting all ungraceful forms of nose, leaving the skin intact. He classifies unshapely noses into five principal groups: blobby, crooked, saddle-shaped, long, and broad. To improve them M. Bourguet operates through the nares under local anaesthesia, separating the skin from the subjacent framework, removing exuberant bone and cartilage by means of a small saw or a file in the case of bosses, and reapplying skin and subcutaneous tissue to the amended framework. In noses which deviate from the straight M. Bourguet luxates the nasal bones, and after fracturing the perpendicular plate of the ethmoid accurately centres the nasal framework, holding it in position by means of an intranasal splint or an external dressing until consolidation is complete. Saddle-backed noses are corrected by taking a fragment of the required size from the tibial crest enveloped in its periosteum and grafting it under the skin of the nose. In dealing with a nose that is too long M. Bourguet removes a triangular piece of the septum and triangular cartilage so as to restore the nose to its normal proportions. Finally, he corrects noses that are too broad by bringing together the ascending processes of the maxilla towards the mesial line, and removing a portion of the cartilage of the ala. After disappearance of the œdema transformation is complete without a vestige of scar.

## Obituary.

WALTER HAMILTON HYLTON JESSOP, M.A.,  
M.B. CANTAB., F.R.C.S. ENG.,

PRESIDENT OF THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM AND SENIOR OPHTHALMIC SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

IT is with very great regret that we have to announce the death on Friday last, Feb. 16th, of Mr. Walter H. H. Jessop from pneumonia after a short illness. Little more than a week ago he was apparently in excellent health, full of the energy and almost youthful spirits with which his friends were so familiar. It is doubtful, however, if before he was attacked with the fell disease to which he succumbed he was in as healthy a state as his natural buoyancy seemed to indicate. Ever since the beginning of the war he had given himself unsparingly to the services of wounded soldiers at No. 1 General Hospital, Camberwell, and elsewhere, in addition to the performance of his ordinary duties at St. Bartholomew's Hospital and at home. Moreover, as we shall have occasion to mention later, he was enthusiastically engaged upon several schemes for the organisation and advancement of British ophthalmology, all of which entailed heavy labours, such as would have tired out a much younger man. A recent appreciation of the late Duke of Norfolk has said that "he died 70 years young." It is equally appropriate to say that Jessop died 64 years young, for he was young in his physical strength, young in his thoughts, his enthusiasms, his aspirations, and even in his foibles. Some years ago he had a very serious motor accident, and it may be that he was never quite the same man after it. Yet there was little evidence of such being the case, and if he felt shaken he concealed it successfully even from his intimate acquaintances.

Walter Jessop was born in 1853, being the son of Walter Jessop, F.R.C.S., of Cheltenham. He was educated at the College, Cheltenham, until his father's death, when he was transferred to the Modern School, Bedford, where he gained the Harpur exhibition of £200. He then started working for the Indian Civil Service, but in 1871, having won the valuable Tancred studentship in medicine, which is held at Gonville and Caius College, Cambridge, he proceeded to that College. In 1876 he graduated in Arts at Cambridge, and joined the medical school of St. Bartholomew's Hospital for the completion of his medical studies. He became a Member of the Royal College of Surgeons of England in 1880, and four years later took the Fellowship, graduating also in medicine at Cambridge. He joined the teaching staff of St. Bartholomew's Hospital in 1882 as demonstrator of anatomy, and remained in the dissecting rooms of the hospital for nearly 13 years. He proved himself an excellent teacher, and was, moreover, though strict, popular with the students. At this time, in spite of early evidences as to the direction which his energies would take, his actual professional future was uncertain, owing to the long period before any vacancy occurred at St. Bartholomew's for an ophthalmic surgeon. But in 1894, on the resignation of Mr. Henry Power, he became junior ophthalmic surgeon to the hospital, the holder of that post, Mr. Bowater Vernon, taking Mr. Power's appointment. He had already been elected surgeon to the Central London Ophthalmic Hospital and ophthalmic surgeon to Paddington Green Children's Hospital. His election to the staff of St. Bartholomew's Hospital, though warmly contested, had already been amply justified. In 1885, soon after the introduction of cocaine by Koller, Jessop made an exhaustive research on the action of this drug on the eye. It was a painstaking and well-executed piece of work, and the conclusions at which he arrived have been confirmed by all later observers. Henceforth he devoted himself to the clinical aspects of his special subject, but these papers on cocaine prove that, had he been so minded, he would probably have been successful in more purely scientific research. In 1887 and 1888 he delivered the Hunterian Lectures at the Royal College of Surgeons of England, taking for his subject the anatomy and physiology of the intraocular muscles, and in the latter year he made a communication on the same subject to the International Ophthalmic Congress. From 1885 until his death every volume of the Transactions of the Ophthalmological

Society contains papers and communications from his pen. It is true that they consist chiefly of reports of cases and contributions to discussions, but they combine to show a vast knowledge of ophthalmology and an eminently level-headed clinical acumen. He was always abreast of the times, and never more so than in the last years of his life. This fact is borne out by his recent communications to medical societies on war injuries of the eye, trench nephritis, and other cognate subjects. In addition to contributions to societies and medical journals Jessop wrote articles on ophthalmic subjects in various surgical text-books, while in 1898 he published an excellent manual on "Diseases of the Eye," of which a second edition appeared in 1908.

It would be wholly unjust, however, to judge Jessop's place in British ophthalmology by his writings only, for he was not a ready writer. As a matter of fact, he made a unique position for himself. Filled with a patriotic desire to advance British

ophthalmology and to proclaim and insist upon its just recognition by other nations he constituted himself an international intermediary. He was a member of the Belgian, Spanish, and American Ophthalmological Societies *honoris causa*, and also an honorary member of the Budapest Medical Society in his capacity as an ophthalmologist. There was scarcely an International Congress of Medicine or Ophthalmology which he did not attend, and he was frequently present at the annual meetings of the Heidelberg and Paris societies, nearly always of recent years being voted to take the chair at one of the sessions. No one in England knew more continental ophthalmologists and many of them were his intimate friends. His home was always at their disposal, and Landolt, Straub, Axenfeld, and a host of others were often his guests. It was one of his greatest foreign

WALTER H. H. JESSOP, M.A., M.B. CANTAB., F.R.C.S. ENG.,  
PRESIDENT OF THE OPHTHALMOLOGICAL SOCIETY.

friends, Professor Straub, of Amsterdam, who suggested to Jessop that the war had knelled the doom of German ophthalmic literature. The ophthalmic surgeons of neutral countries, who had been accustomed to send their papers to German journals, were now deprived of an international medium of publication. Jessop, who had so soon to deplore the loss of his friend, seized upon the opportunity then presented. In 1915 he was elected President of the Ophthalmological Society. He immediately made use of this commanding position to further the project of a single all-embracing and thoroughly representative British Journal of Ophthalmology. He lived to see the venture launched most successfully. He worked day and night for the new journal from the time of the inception of the idea to the very day when illness

prostrated him. If British ophthalmologists wish to erect a monument to him, *aere perennius*, none could be more appropriate than to make the journal in every respect worthy of the high ideals which he set before them. The suggestion that the existing British journals of ophthalmology be amalgamated with a view of forming a representative periodical, though it originated from Straub, was seized upon by Jessop with characteristic foresight and energy. He personally wrote to most of the senior members of the Ophthalmological Society, suggesting the establishment of a really representative British Journal of Ophthalmology at or before the termination of the war, and called a meeting at his house in Harley-street last summer. The idea was then approved, and a sub-committee of seven was formed to make arrangements with the existing ophthalmological journals as regards amalgamation, and to draw up a definite scheme. The sub-committee met

on several occasions, and reported that a limited liability company with a capital of £5000 should be formed to publish such a journal, which should incorporate the *Royal London Ophthalmic Hospital Reports*, the *Ophthalmic Review* and the *Ophthalmoscope*. Further recommendations were that the shares in the company be held only by registered members of the medical profession and that no transfer of shares be registered without the consent of the directors. This report was approved by the original committee and a general meeting of ophthalmologists to consider the proposals was called at the house of the Royal Society of Medicine towards the end of September. Jessop, who was appointed managing director of the new company, threw himself heart and soul into the onerous work of inaugurating the Journal, and it can scarcely be doubted that in doing so he severely taxed his strength.

As President of the Ophthalmological Society he took a paternal interest in the Bowman Library, which was founded by the society. But when the Section of Ophthalmology of the Royal Society of Medicine came into existence, and changes in the constitution of the Ophthalmological Society occurred, the latter body generously handed the Bowman Library over to the safe keeping of the Royal Society of Medicine. Jessop was elected librarian of the Bowman Collection, and he had already, with his usual vigour, commenced to fill the lacunæ upon its shelves. At the time of his death he was engaged upon this, and also upon another and larger piece of work, for the welfare of ophthalmology. In addition to the annual meeting of the Ophthalmological Society, which has

become an annual congress, there is another ophthalmological congress which meets yearly at Oxford, and there are several small ophthalmological societies scattered over the United Kingdom. It was his object to affiliate them all to the old society in order that there might be greater unity of purpose and that all should be permeated with the same spirit of goodwill. We understand that the negotiations to this end were proceeding satisfactorily, and we hope that loyalty to the lost leader will be an additional incentive to bringing them to the conclusion which he would have wished.

It remains to say a few words about Jessop the man. He was a man of the world in the best sense of the term. We have spoken of his perennial youth, his energy, and his *bonhomie*. His tastes were wide. He delighted in art and had an excellent judgment. He was a recognised connoisseur of certain modern artistic work. Of all kinds of painting he was an appreciative critic and sometimes a pioneer, being quite uninfluenced by popular or passing fashion. From instinct as a collector he anticipated the rise in prices obtained for prints and lithographs, always buying with great prudence. Of his Whistler prints he was justly proud; some of them are unique, and examples from his collection may be seen at the current exhibition at the Royal Academy. Jessop shared with his accomplished wife that taste and discrimination which made him welcome at the Burlington Fine Arts Club, of which he was a member, and he was a familiar figure at the private views of different galleries, where he was often a discreet and judicious purchaser. He loved music, and was a frequenter of the opera and classical concerts. He was fond of good literature, English and foreign. Perhaps he was never happier—at least, so it seemed to his guests—than when he and his wife, who shared, and, it may be, helped greatly to inspire, his artistic tastes, were entertaining friends in Harley-street or at his charming riverside house at Sutton Courtenay. Not that his country life was one of mere relaxation. He took his duties as a magistrate very seriously, was most punctual in attendance at the Bench, and was constantly asked to serve on special committees dealing with important public business.

Mr. Treacher Collins writes:—

The sudden and unexpected death of Mr. Walter Jessop has deprived the ophthalmological world of one of its most prominent and leading representatives. There are probably few British ophthalmic surgeons who were so widely known and esteemed as Jessop. He was a man richly endowed with what has been aptly termed “herd instinct.” He devoted much time and great energy in the promotion of the interests of his hospital, of his profession, and more particularly of that branch of the profession in which he specialised. He was never happier than when he found himself associated with others in the promotion of mutual interests. In the years before the war he was constantly flitting to and fro to different parts of the continent to attend meetings of the numerous ophthalmological societies with which he was connected, and over those proceedings he was frequently invited to preside. Quick to take up new ideas, and with a keen appreciation of what was good, he brought back from these meetings valuable information which he was always ready to impart to his less cosmopolitan colleagues. Jessop was reaching that time of life when an ophthalmic surgeon’s methods and opinions tend to become more reminiscent of the past than in accordance with new ideas. Anyone, however, who conversed with him on professional subjects soon came to recognise that there was nothing of the bache number about him. Though not naturally a fluent speaker, having a peculiar jerky manner of delivery, his instinctive sympathy with the feelings of his fellows was so great that he was often able to expound in a telling and forcible way the ideas which they desired to have expressed. It was this same instinctive sympathy which made him such an agreeable host and such a successful organiser. His generous hospitality at his house in Harley-street, which was at one time the residence of Mr. Gladstone, will long be remembered by many of his colleagues. Jessop was certainly seen at his best at the head of his table surrounded by leading ophthalmologists from all parts of Europe. Keenly appreciative of humour and anecdote, he had the happy knack of grouping his guests and drawing them out so as to promote the general interest and enjoyment. Never were Jessop’s tactful energy and powers of organisation so conspicuously manifested as in the latter years of his life. In 1915 he was elected President of the Ophthalmological Society of the United Kingdom, in the welfare and proceedings of which he had always taken a lively and active interest. On the assumption of the office of President his

exertions on its behalf became redoubled, with the result that, notwithstanding the war, its annual congress of three days last year was by common consent regarded as the most interesting and successful that it has held.

Mr. Holmes Spicer writes:—

From the time he left Cambridge perhaps the greatest interest in Jessop’s life was St. Bartholomew’s Hospital. After serving on the junior staff he was elected demonstrator of anatomy in 1882, which post he retained till he became ophthalmic surgeon in 1894. It was during this time that he made life-long friendships with colleagues such as Bruce Clarke and Lockwood, both of whom are now gone, but also with successive generations of Bart’s, men who owed much to his teaching. Life at this time was a struggle, there was no clear opening before him, it needed courage and tenacity to succeed. His election at Bart’s was strongly contested, and it was only later that success came to him: with it the sunnier side of his nature developed, and his real character showed itself. There was a tradition in the eye department at St. Bartholomew’s, and Jessop, who, though a Liberal in politics was by nature Conservative, set great store by the tradition; for example, it had been the custom to do the simple extraction of cataract without iridectomy, and Jessop followed the custom. There were ways of treatment, tricks of bandaging hallowed by custom, and justified by experience, which he maintained through life. As a surgeon he rather followed the French school. He had received austere training at Moorfields under Nettleship and others which made his practice solid. As a colleague I can only say that during the 16 years of our association we never had a disagreement, and rarely a difference of opinion; he was thoughtful and kind. As a story-teller he could entertain one for hours with the peculiarities and weaknesses of the world great and small; his method was impressionistic—a word, a half-sentence, or a smile supplied the place of lengthy explanation. His love of art was genuine and enthusiastic. I remember spending a delightful afternoon with him at Sir Hugh Lane’s collection of modern pictures in Dublin; although he did not himself practise any art, his judgment, taste, and knowledge were excellent. He loved to show his collections; his Whistler lithographs are famous. He would tell of the jealousies of collectors, and of a rival who, after offering very large sums for a unique specimen, finally handed him a blank cheque to fill in as he liked in exchange for the picture; that cheque was not filled in. At his country home he was always glad to see old friends or pupils, or to welcome distinguished foreign colleagues. Under his roof the guest was free to follow his own way, to join him in a morning swim in the river or a hard spell of gardening. He lived the free life of the country whenever he could get away from his work, and took his full share as a country magistrate and in other ways in the social life of his neighbourhood.

Walter Jessop lived a full life and has died almost suddenly when that life was at its fullest. The utmost sympathy will go out to his widow and daughter on their great loss.

CLAUDE LAMONT WHEELER, A.B., M.D.,  
EDITOR OF THE “NEW YORK MEDICAL JOURNAL.”

Dr. C. L. Wheeler died at his residence, Brooklyn, N.Y., on Dec. 30th, aged 52.

Claude Lamont Wheeler was born in Montreal on March 5th, 1864, the son of Dr. Thomas Brown Wheeler, and a nephew of William Wheeler, a former Governor of the State of Rhode Island. He took his degree in Arts at Laval University in Quebec, and graduated in medicine from McGill University, Montreal, in 1889. Twenty-six years ago he went to New York, and in 1902 he joined the editorial staff of the *New York Medical Journal*, then under the control of Dr. Frank P. Foster, the well-known writer on medical and literary subjects. Dr. Kenneth W. Millican, the late assistant editor of THE LANCET, was associated with Dr. Wheeler in the editorial work of the journal before returning to this country and joining our staff. In 1911, on the death of Dr. Foster, Dr. Charles E. de M. Sajous, of Philadelphia, and Dr. Wheeler became associated in the editorship. During his six years’ tenure of the editorship Dr. Wheeler not only maintained the high standard of the *New York Medical Journal*, but in many directions greatly improved that publication. He was peculiarly well adapted for the position of a medical editor. While his medical knowledge was extensive, his literary gifts were even more conspicuous. He possessed the literary instinct, which was supplemented by a high degree of culture. He was extremely well versed in classical literature, and as a writer he was concise in language and distinguished in style. Moreover, he was an excellent judge of the writings of other people. He knew

several languages, including French, German, Italian, and Spanish, and possessed a somewhat remarkable knowledge of Greek and Latin. To these advantages may be added those of a fine presence, engaging manners, and great tact. Dr. Wheeler was a very versatile man and of a distinctly artistic temperament. He was an amateur actor with decided histrionic gifts, a vocalist with an exceptionally good and well-trained voice, and an accomplished pianist.

Dr. Wheeler had been in failing health for a year or more, but up to within a few days of his death had strictly attended to his editorial duties. He may be said almost to have died in harness. Dr. Wheeler leaves a widow and young daughter.

### EDUARD HAGENBACH,

PROFESSOR OF CHILDREN'S DISEASES IN THE UNIVERSITY OF BASEL.

Eduard Hagenbach, who died recently in Basle at the age of 76, had occupied for 44 years the University chair of pediatrics, which had been specially created for him. The son and grandson of distinguished medical men in the cathedral city on the Rhine, he obtained his medical qualification at the moment when Streckeisen's indefatigable labour had resulted in providing Basle with a children's hospital and attached teaching school, the first of its kind in Switzerland; and after varied experience in Paris and elsewhere Hagenbach succeeded Streckeisen as chief of the children's hospital. To this and to the well-being in general

of the child Hagenbach devoted his life. A colleague says of him: "He understood the soul of the child as hardly another did, and his manner of dealing with children was full of charm, his small patients responding with warm affection in return." The crèches, the infant welfare centres, the children's convalescent homes in and near the city were all due to his strenuous advocacy through good and evil report. He gave many public lectures and contributed alone or with his pupils more than 150 articles on childish ailments to the medical press, chapters on rickets and whooping-cough being among his larger works. He was an enemy of all slipshod methods, and his writings were characterised by care and precision. But more than by these, his memory will be kept alive by the infant welfare movement in Switzerland, of which he was the pioneer.

**THE LATE MR. F. P. LANSDOWN.**—Francis Poole Lansdown, M.R.C.S., L.S.A., honorary consulting surgeon to the Bristol General Hospital, died at his residence at Lydford, Devon, on Feb. 12th, in his 84th year. He had retired from active work for several years, but at one time he had an extensive practice in Bristol and Clifton. He was on the honorary surgical staff of the Bristol General Hospital and formerly lectured on anatomy at the Medical School. He was Surgeon Lieutenant-Colonel (V.D.) of the 1st Gloucester Artillery Volunteers. Mr. Lansdown was much esteemed in Bristol and the district. He leaves a widow and a son, Mr. R. G. P. Lansdown, who is honorary surgeon to the Bristol General Hospital.

## A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

COMMITTEE FOR THE INVESTIGATION OF ATMOSPHERIC POLLUTION: SUMMARY OF REPORTS FOR THE MONTHS ENDING

August 31st, 1916.

† Collected from 20th only.

"Tar" includes all matter insoluble in water but soluble in CS<sub>2</sub>. "Insoluble ash" includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (a) Approx. 9lb. per acre; (b) 2·56 English tons per sq. mile; (c) one gramme per sq. metre; (d) 1/1000 millimetre of rainfall.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved remains the same as published in previous tables.

**ABERDEEN ROYAL INFIRMARY: ANNUAL REPORT.**—The annual report of the Aberdeen Royal Infirmary for 1916 states that during the year 3235 in-patients and 14,572 out-patients received treatment, 94 more in-patients and 678 fewer out-patients than last year. The average number of beds in daily occupation was 238, and the average number of days in hospital of each patient was 27. The death-rate was approximately 6·6 per cent. of cases treated. Deducting the deaths which occurred within 48 hours of the patient's admission, the death-rate was reduced to about 4·8 per cent., as against 5·1 in 1915. There was an increase of £1367 in the ordinary income, but a decrease in patient's payments was regrettably noted. The ordinary expenditure

was £1824 more than in the previous year, the added cost of butcher meat, milk, sugar, and coal accounting for practically the whole of that sum. The average cost per occupied bed was calculated to be £72 2s. 1d. and of each in-patient treated to be £5 3s. 2d. The board recorded their deep regret for the death of Dr. Arthur Hugh Lister, which occurred on July 17th on his way home from Egypt, where he had been on military duty. Dr. Lister had been a member of the honorary staff of the infirmary from March, 1897, as an assistant physician and after as a physician. In addition to his infirmary work, in which he displayed great fidelity and zeal, he rendered conspicuous service in the investigation and treatment of tuberculosis.

# The War.

## THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue :—

### Died.

Lieut.-Col. J. F. Flasham, Australian Army Medical Corps, qualified at Sydney University in 1894 and was in practice in Macquarie-street, Sydney, New South Wales, prior to joining the Expeditionary Force.

*Previously reported Missing, believed Drowned, now reported Drowned.*

Lieut. J. Cropper, R.A.M.C. (see THE LANCET, Dec. 16th, 1916, p. 1034).

### Wounded.

Capt. A. H. Ernst, R.A.M.C., attached Royal Engineers.

Capt. C. W. C. Robinson, R.A.M.C.

Lieut. W. J. Pearson, R.A.M.C., attached Royal Flying Corps.

Capt. W. M. Badenoch, R.A.M.C., attached Welsh Regiment.

Capt. J. H. Cuthbert, R.A.M.C., attached Royal Field Artillery.

Lieut. J. M. Hammond, R.A.M.C., attached Devon Regiment.

## OBITUARY OF THE WAR.

RUSSELL ELIOTT WOOD, M.D., C.M., F.R.C.S. EDIN.,  
LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel R. E. Wood, whose death occurred suddenly at Dunbar on Feb. 9th, came of a family long distinguished in the medical annals of Edinburgh. He was educated at the Edinburgh Academy, where he took a keen

interest in athletes, afterwards graduating M.B., C.M. at Edinburgh University, later taking the Fellowship of the Royal College of Surgeons of Edinburgh, on the President's Council of which he served. He was also on the governing board of the School of Medicine of the College, and an examiner for the triple qualification. He held many appointments, and up to the time of his death was visiting physician to Donaldson's Hospital, Edinburgh. In his early days he served in the Zulu War, and as medical officer

to the Lanarkshire Yeomanry had maintained his connexion with the Army, rising to the rank of Surgeon Lieutenant-Colonel. Shortly after the outbreak of war he volunteered his services and was appointed to his old regiment.

Writing of Colonel Wood, a friend and colleague says of him: "He was genial and kind-hearted, an excellent practitioner, a keen sportsman, and a loyal friend. He will be sorely missed."

## DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war :—

Second Lieut. J. H. W. Stevenson, C.S.I., J.P., Indian Army, younger son of Surgeon-General Stevenson, of Castle-town, Isle of Man.

Capt. F. W. H. Simpson, Royal Garrison Artillery, attached Royal Flying Corps, only son of Professor W. J. R. Simpson, C.M.G., of Regent's Park, London.

Lieut. J. St. E. Cardew, R.N. (retired), younger son of Mr. G. A. Cardew, M.R.C.S., of Cheltenham.

## THE HONOURS LIST.

The following promotions of and awards to medical officers are announced :—

C.M.G.—Col. P. Hehir, C.B., I.M.S.

To be *Brevet Colonels*.—Lt.-Col. W. G. Beyts, R.A.M.C.; Lt.-Col.

L. P. More, R.A.M.C.

To be *Brevet-Lieutenant-Colonels*.—Maj. A. W. C. Young, I.M.S.;

Maj. F. A. F. Barnardo, I.M.S.

*Bar to Military Cross*.—Temp. Capt. A. C. Hancock, M.C., R.A.M.C.

### Foreign Decorations.

The names of the following medical officers appear in a lengthy list of decorations awarded by the Allied Powers at various dates to the British forces for distinguished services rendered during the course of the campaign, which the King has given unrestricted permission to wear :—

*By the Emperor of Russia.*

*Order of St. Anne, 3rd Class (with Swords)*.—Col. Gerald Cree, C.M.G., A.M.S.

*By the King of Serbia.*

*Order of the White Eagle, 2nd Class (with Swords)*.—Surg.-Gen. Francis Harper Treherne, C.M.G.

*Order of the White Eagle, 3rd Class (with Swords)*.—Lt.-Col. (temp. Col.) A. E. C. Keble, D.S.O., R.A.M.C.

*Order of the White Eagle, 4th Class (with Swords)*.—Maj. R. W. Knox, D.S.O., I.M.S.; Maj. R. S. McGregor, Aust. A.M.C.; Lt.-Col. J. R. Whait, R.A.M.C.; Maj. R. J. Bradley, I.M.S.; Lt.-Col. (temp. Col.) D. J. Collins, R.A.M.C.; Maj. W. S. Patton, I.M.S.; Lt.-Col. R. Steiman, R.A.M.C.

*Order of the White Eagle, 5th Class (with Swords)*.—Capt. H. J. M. Curtsejee, I.M.S.; Capt. J. G. F. Hosken, R.A.M.C.; Capt. W. R. C. Mainwaring, Aust. A.M.C., attached Aust. Light Horse; Temp. Capt. R. A. Mansell, R.A.M.C.; Capt. R. Proutfoot, R.A.M.C.; Capt. H. G. Trayer, R.A.M.C.; Capt. (temp. Lt.-Col.) H. Wade, R.A.M.C.; Capt. (temp. Maj.) E. T. Burke, R.A.M.C., Spec. Res.; Capt. H. Falk, I.M.S.; Capt. E. S. Goss, I.M.S.; Capt. V. B. Green-Armystage, I.M.S.; Lt. N. S. Jatar, I.M.S.; Temp. Capt. J. A. Arkwright, R.A.M.C.; Capt. R. C. Carlyle, R.A.M.C.; Capt. (temp. Maj.) E. L. Rowse, R.A.M.C.

*By the King of Belgians.*

*Officier de l'Ordre de la Couronne*.—Temp. Maj. H. S. Souttar, R.A.M.C.

## THE CENTRAL MEDICAL WAR COMMITTEE.

At a meeting of the Central Medical War Committee on Feb. 21st the chairman, Mr. Verrall, speaking on the question of the immediate outlook in respect of additional doctors for the Army, and particularly in regard to the matter of calling up the whole or part of the enrolled men, said that some new departure would, in his opinion, have to be made, because even if the enrolled men were immediately called up there would not be obtained the numbers demanded by the War Office. A statement was made by Dr. Buttar, the chairman of the Executive Subcommittee, in the course of which he urged that every effort should, in the first place, be made to obtain the last man possible from those of military age. He considered that there were several reasons for postponing an immediate call upon enrolled men, in view of the possible development of the scheme of the Director-General of National Service and the proposal which was in the air to make a general call for national service upon all classes of the population under the age of 50. He thought that it would be well to take an early opportunity of reviewing the War Office demands in the light of recent developments.

The Committee discussed again the question whether the whole-time service of the country had contributed their fair quota of medical recruits to the Army. It was reported that an interview had taken place with representatives of the Local Government Board and the Board of Education, when facts were brought forward showing that in respect of the Poor-law Service the Local Government Board did not feel itself in a position to make any further serious calls, while it had already spared a large number of whole-time officers on the public health side. Readiness was expressed both by the Local Government Board and the Board of Education to consider any individual calls which the Committee might think it necessary to make upon their officers, but it was pointed out that the Boards had no power to call up medical men in the employment of local authorities, although they were willing to represent to such authorities the need for making the necessary sacrifices.

Finally, the Committee instructed the Executive Subcommittee to inquire carefully into the matter of the enrolled men, and to report to the full Committee on the question of notifying Local Medical War Committees that the necessity of calling upon enrolled men might arise in the near future, indicating in each case the number that it was estimated ought to be supplied from the area.

## THE DISABLED SAILOR AND SOLDIER.

At the third Galton anniversary meeting on Feb. 16th Major Leonard Darwin, while admitting that the greatest eugenic task of all lay in promoting the early return to work after the war of the uninjured man, pointed out the need of the British Empire for the fine qualities of courage, endurance, and patriotism shown by the men of our volunteer armies. It was necessary to ensure that the men who returned disabled from abroad should have at least an equal opportunity with those, who had proved unfit to serve in the Navy or Army, of forming homes and passing on their good qualities to future generations. The hardships to be endured during active military service were such that even the soundest of men were liable to suffer from disease, but those men discharged for disease contracted at the front were nevertheless, as a class, capable of handing on a strong constitution to their children.

The subject of the manual training of the disabled soldier in military hospitals came up last week in Parliament, when Lord H. Cavendish-Bentinck asked the Under Secretary for War whether with reference to a recent Army Council Instruction ordering the discontinuance in military and auxiliary hospitals, convalescent camps, and command depôts of instruction in trades and occupations, workshops, and poultry-farms, he would state the reason for this order, putting an end to teaching which was very beneficial to the mental and bodily health of the patients. Mr. Macpherson, in reply, regretted that no hope could be held out of the order being reconsidered. Hospitals, convalescent camps, and command depôts generally, if they were to fulfil their proper functions of getting the men fit for discharge as quickly as possible, and so setting the accommodation free for other patients, must be entirely devoted to the purposes of medical treatment. There were, he added, special hospitals where manual training formed part of the sanctioned system of curative treatment. In the debate on the Consolidated Fund Bill, Lord H. Cavendish-Bentinck returned to the subject and said:—

There ought to be a complete system of out-patient treatment of discharged soldiers. It should not be beyond the resources of the Army authorities to provide accommodation both for the freshly wounded and for those recently convalescent in order that they might get perfectly cured. He could not help thinking that the War Office had taken a retrograde and reactionary step in issuing an instruction abolishing all the trade schools and classes in hospitals and auxiliary hospitals. It had gone so far as to forbid people in charge of hospitals keeping poultry. People used, he said, to rely on mechano-therapy, but it was now being found that disabled men could be restored better by technical training than by mechanical appliances. It had further been discovered that there was no likelier way to restore a man suffering from shell-shock and nervous disorders than to give him some useful occupation. It was deplorable if the Army authorities were to abolish the attempt of giving men like this something to do. If the Statutory Committee had been able to organise a perfect system of training the case would be different.

**THE ARMY AUTHORITIES AND INCURABLE SOLDIERS.**—Our Dublin Correspondent writes: Some weeks ago the committee of management of the Royal Hospital for Incurables, Dublin, wrote to the Government authorities suggesting the establishment of a Government hospital in Ireland for the care of sailors and soldiers who had become afflicted by incurable diseases as the result of war conditions. At its last meeting the committee had under consideration a reply received from Surgeon-General Sir Richard Ford, D.D.M.S., Irish Command. He wrote that the establishment of a special hospital for the purpose suggested would entail considerable expense and might not be necessary. As an alternative, arrangements were being made with the Red Cross authorities to send incurable soldiers to the several county infirmaries, the cost of their maintenance to be borne by the Red Cross funds. The committee of management of the Royal Hospital for Incurables has published a strong protest against this proposal, which, on every ground, seems to be unsuitable. The county infirmaries are active surgical hospitals, quite unfitted to serve as permanent homes for incurable patients, whose presence, moreover, would interfere with the normal working of the infirmary. For another reason the proposal appears even more improper. There is no justification for the attempt

to shift the responsibility for the care of incurable soldiers from the Army authorities to a voluntary fund. Men who have been so unfortunate as to suffer permanent disability as a result of war service are entitled to the security of maintenance by the State, and are not to be put off as mendicants dependent on voluntary charity. It is generally felt that if the scheme outlined by Surgeon-General Ford is persisted in the county infirmaries will prove only half-way houses to the workhouse wards.

**HEALTH OF THE GERMAN ARMY.**—To the wireless summary of the health statistics of the German Army, given in THE LANCET of Jan. 20th, p. 126, during the first two years of war, we can now add the actual official figures of illness per 1000 of the actual strength:—

	1st year.	2nd year	1st year.	2nd year
Small-pox	0·01	0·00	Measles	0·07
Typhoid	5·60	1·40	Diphtheria	0·24
Typhus	0·03	0·08	Tuberculosis	2·90
Dysentery	2·80	1·80	Pneumonia	6·80
Asiatic cholera	0·32	0·24	Pleurisy	7·70
Recurrent fever	0·17	0·80	Nerve diseases	24·30
Scarlet fever	0·18	0·15		21·50

The only diseases in the list showing any increase are typhus (nearly trebled), recurrent fever (nearly quintupled), and diphtheria (more than doubled). The last named has had the same increased prevalence among the civilian population.

## THE SERVICES.

## ROYAL ARMY MEDICAL CORPS.

Majors (acting Lieutenant-Colonels) relinquishing their acting rank on reposing: W. J. P. Adye-Curran, W. F. H. Vaughan, Major H. H. A. Emerson, D.S.O., to be Acting Lieutenant-Colonel whilst in command of a Casualty Clearing Station.

To be Acting Lieutenant-Colonels whilst in command of a Field Ambulance: Major J. P. Silver, D.S.O., Capt. (Acting Major) W. J. H. Bell, D.S.O., Capt. R. B. Phillippe, Major G. W. G. Hughes, D.S.O., Capt. A. I. Fortescue.

To be Acting Lieutenant-Colonels whilst in command of a Stationary Hospital: Major M. Sinclair, Major R. B. Ainsworth, D.S.O.

To be temporary Lieutenant-Colonels: Lieut.-Col. Sir Ronald Ross, K.C.B. (Major, retired, I.M.S.), J. W. W. Stephens, Temp. Major R. B. Kelly (Captain, R.A.M.C., T.F.).

Temp. Capt. R. H. J. Swan to be temporary Major.

Temp. Capt. (acting Major) R. H. Jones relinquishes his acting rank on reposing.

To be acting Majors: Capt. C. H. H. Milner, R.A.M.C., T.F., whilst in command of General Hospital; Capt. W. J. Tobin, whilst in command of Field Ambulance; Temp. Capt. A. B. Seller, whilst in command of troops on a hospital ship.

Temp. Capt. (local Major) R. B. K. Paton relinquishes his local rank on reposing.

Temporary Lieutenants (Canadian Militia), Canadian A.M.C., to be temporary Captains: H. E. Brown, from Lieutenant, R.A.M.C., P. W. Barker, from Captain, R.A.M.C.

Temporary Lieutenants to be temporary Captains: J. Cameron, H. A. G. Hadden, G. W. Spencer, W. A. Cochrane, W. G. Parker, J. H. P. B. Barrett, B. Cox, W. Dickson, P. A. Reckless, G. J. Jones, S. J. C. Fraser, D. Burns, I. Feldman, E. E. Hart, S. A. W. Munro, D. H. Hall, J. J. O'Neill, D. Lee, G. P. White, R. M. Rowe, W. Brownlie, R. Johnson, T. Dowzer, E. J. Clark, W. P. Speedy, R. A. Warters, A. D. Moffat, J. J. Clarke, R. E. Illingworth, A. D. Hunt, A. W. Mather, A. C. Tait, O. W. C. Robinson, W. M. Buchanan, W. J. Pearson, E. L. Christoffels, C. F. MacLachlan, J. G. M. Moloney, A. D. Buchanan, W. D. D. Small, R. M. Hewitt, J. P. Fairley, M. C. Bridgeman, A. McNally, A. E. McCulloch, G. H. Hanley, G. H. Kearny, H. O. Fox, E. W. Martin, W. M. Muirhead, J. Bain, R. R. Watts, C. M. G. Elliott, P. W. Craig, J. Oag, A. McL. Pilcher, J. F. St. J. Annesley, A. H. Donaldson, J. McF. Grier, F. R. Marriott, G. W. Huggins, B. C. Sparrow, A. H. Ernst, R. N. Craig, A. H. G. Burton, W. G. Porter, J. A. MacArthur, T. C. Bowes, B. Graves, D. S. Robertson, J. H. C. Fegan, H. Younger, A. J. L. Speechly, A. N. Cox, W. S. T. Connell, H. G. Carlisle, F. C. Stewart.

To be temporary Captains: G. O. Scott, Canadian A.M.C.; W. . Hale, Canadian A.M.C.

B. S. Phillips to be temporary Honorary Lieutenant whilst serving with British Red Cross Hospital, Netley.

Temporary Captains relinquishing their commissions:—W. B. Thompson, R. J. H. Cox, C. L. Morgan, F. A. Bainbridge, J. Fettes, O. F. McCarthy, W. Winslow, C. H. Phillips, C. P. V. MacCormack, C. W. Roe, R. H. Fothergill, B. M. Collard, R. B. Jackson, T. H. Agnew, J. P. Laverty, H. H. Scott, C. G. R. Pennant (on account of ill-health).

The undermentioned, having resigned their appointments at the Welsh Hospital, Netley, relinquish their commissions: Temp. Hon. Capt. J. S. Rowlands and T. G. Evans, Temp. Hon. Lieuts. W. MacAdam and D. J. Harries.

L'ebenants relinquishing their commissions:—T. M. Body, H. A. R. E. Unwin, D. M. Hanson, H. Farncombe, J. Massey, M. J. Harkin, W. A. L. Marriott, D. A. Thomson, A. Brebner, H. Tonks, G. O. Scott, C. M. Scott, J. Dunbar, S. M. Comb, C. M. Jones-Phillipson, F. J. C. Blackmore, J. Bryan, O. Le F. Milburn, H. W. P. Parrott, R. A. R. Green, T. Winning, G. F. Palmer, L. W. Oliver, A. L. Singer, I. J. Balkin, E. G. Pringle, W. Stevenson, M. Campbell, R. Montgomery, G. Fitz-Gerald, C. S. Rivington, W. B. Mercer, S. Stockman, F. J. Rager, J. McConnell, W. M. Nairn, H. de L. Crawford, W. W. Jones.

Temporary Lieutenants relinquishing their commissions: J. S. Johnson, T. G. H. Drake, A. H. B. Kirkman, and A. E. Whitmore, and A. S. Paterson (on account of ill-health).

The undermentioned, having resigned their appointments with No. 8 British Red Cross (Baltic and Corn Exchange) Hospital, relinquish their commissions: Temp. Hon. Lieuts. C. H. Drennan and C. E. Sparks.

SPECIAL RESERVE OF OFFICERS.

Capt. H. M. Williams to be Acting Major whilst in command of a Field Ambulance.

Lieutenants to be Captains: T. Blackwood, J. P. Broom, A. C. Brown, J. W. Dalglash, J. F. Duthie, J. Ewing, E. G. S. Hall, R. W. MacDonald, D. B. McIntosh, J. W. Maclean, A. F. McMillan, R. Rodger, J. A. Buchanan, G. Lapage, J. M. H. Campbell, P. D. H. Chapman, E. B. Alabaster, J. B. Steven, K. J. T. Wilson, R. Isbister, T. Gray, M. Dwyer, J. M. Downie, H. S. Moore, R. B. Stewart, R. L. Portway, D. F. Standing, R. J. Staley, W. J. Vance, W. F. T. Haultain, G. J. Key, A. H. Craig, G. Ewen, W. D. Whamond, D. D. Evans, W. H. Dye, G. E. Kidman, F. J. Murphy, A. Fowler, A. G. Stevenson, A. C. MacDonald, O. Johnston, W. C. Borrie, S. J. Henderson, R. B. Hick, W. O. F. Sinclair.

Lieut. (on probation) J. P. Macnamara is confirmed in his rank.

To be Lieutenants: J. H. Thomas, D. J. Thomas, J. Burke, H. D. McIlroy, H. St. H. Ve-tue, C. J. Penny, S. A. T. Ware, H. J. Blampied, R. R. Traill, L. G. Blackmore, L. S. Gathergood, K. N. G. Bailey, M. C. Joint (from University of London Contingent, O.T.C.), H. Franklin (from Leeds University Contingent, O.T.C.), R. W. Lush, B. R. Longstaff, W. Andrew.

Capt. J. O. Hamilton relinquishes his commission on account of ill-health.

Lieut. (on probation) A. F. Grimby relinquishes his commission on appointment to Royal Navy.

TERRITORIAL FORCE.

Capt. R. A. Hooper, from 1st Northern General Hospital, to be Captain.

Capt. (temp. Major) R. W. Brimacombe to be Acting Lieutenant-Colonel whilst commanding a Casualty Clearing Station.

Capt. A. G. Whitfield relinquishes his commission on account of ill-health.

Capt. (temp. Lieut.-Col.) H. N. Goode relinquishes his temporary rank on ceasing to command a Field Ambulance.

Lieut. T. L. Ashforth to be Captain.

Capt. (temp. Major) C. S. Brebner and G. Mackie to be acting Lieutenant-Colonels whilst commanding a Field Ambulance.

Lieut. W. A. Milne to be Captain.

Capt. (temp. Major) J. Grounds relinquishes his temporary rank on alteration in posting.

W. J. Read to be Lieutenant.

HOUSEHOLD CAVALRY.

Surg.-Maj. J. H. Power to be Surgeon Lieutenant-Colonel.

DEATHS IN THE SERVICES.

Surgeon-General Sir Benjamin Franklin, K.C.I.E., honorary physician to the King, suddenly, at his residence, Westhay, East Sheen, on Feb. 17th, aged 73. He entered the Indian Medical Service in 1869, and after serving at Lucknow and Simla, held the position of surgeon to the Earl of Elgin, Viceroy of India (1894-99), subsequently officiating as Inspector-General of Hospitals in Bengal, the North-West Provinces and Oudh, and Punjab. He was British delegate to the International Sanitary Conference at Rome in 1907, and again at Paris in 1911-12. Sir Benjamin Franklin had held the post of Director-General of the Indian Medical Service and that of Sanitary Commissioner with the Government of India. He was a Knight of Grace of the Order of St. John of Jerusalem, and an active member of the Council of the British Red Cross Society. He received the K.C.I.E. in 1903. Although he had been in failing health since September last, he, nevertheless, continued to work as a member of the Red Cross Executive at the headquarters in Pall Mall.

URBAN VITAL STATISTICS.

(Week ended Feb. 17th, 1917.)

*English and Welsh Towns.*—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18,000,000 persons, the annual rate of mortality was equal to 22·5, against rates steadily rising from 16·2 to 21·3 per 1000 in the four preceding weeks. In London, with a population of more than 4,000,000 persons, the death-rate was 23·3, or 1·1 per 1000 higher than that recorded in the previous week; in the remaining towns the rate ranged from 13·5 in Ilford, 14·0 in West Hartlepool, and 15·0 in East Ham, to 33·9 in Warrington, 34·1 in Hastings, and 38·7 in Wigan. The principal epidemic diseases caused 299 deaths, which corresponded to an annual rate of 0·9 per 1000, and included 133 from measles, 52 from diphtheria, 49 from infantile diarrhoea, 37 from whooping-cough, 17 from scarlet fever, and 6 from enteric fever. The deaths from measles, scarlet fever, and whooping-cough were in excess of the average in the three preceding weeks; measles caused a death-rate of 2·2 in Warrington, 2·6 in Ilford, and 6·0 in Wigan. The 806 cases of scarlet fever and the 1436 cases of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 5 and 9 in excess of the numbers at the end of the previous week. Of the 7183 deaths from all causes in the 96 towns, 273 resulted from violence. The causes of 76 of the total deaths were uncertified, of which 14 were registered in Liverpool, 13 in Birmingham, and 6 in London.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death rate was equal to 20·1, against 17·7 and 17·9 per 1000 in the two preceding weeks. The 431 deaths in Glasgow corresponded to an annual rate of 20·1, against 23·3 per 1000 in London, and included 12 from whooping-cough, 7 from measles, 4 from infantile diarrhoea, 3 from diphtheria, and 1 from scarlet fever. The 136 deaths in Edinburgh were equal to a rate of 21·4 per 1000, and included 8 from whooping-cough, 3 from measles, and 2 from diphtheria.

*Irish Towns.*—The 208 deaths registered in Dublin were equal to an annual rate of 27·2, or 0·9 per 1000 less than in the previous week, and included 5 from measles, 2 from infantile diarrhoea, and 1 from whooping-cough. In Belfast the death-rate was 29·9 per 1000; the 225 deaths from all causes included 3 from measles, 2 from whooping-cough and 1 from infantile diarrhoea.

"Audi alteram partem."

OFFICIAL MEDICINE AND THE THRIFTY SPIRIT.

To the Editor of THE LANCET.

SIR,—I see that according to the *Times* the Royal Society of Medicine, a day or so ago, entertained Sir Alfred Keogh to dinner at the Café Royal. As a Fellow of the Society, I may point out that it was not the Society but the Council Club which did this. Let me say at once that I am an ardent admirer of Sir Alfred Keogh and the work he has done for the Army, and the profession would honour itself in honouring him, in any way that might be thought fit, when the war is over.

I fail, however, to see how the Council Club of this Society can justify a dinner of such a kind at the Café Royal in present circumstances. Surely, Sir, at a time when we are threatened with a shortage of the very necessities of life, and at a time when the Food Controller has placed us on our honour not to overstep our food allowance, these gentlemen might find something better to do than to feast at the Café Royal. It is a curious fact that even among some of the leaders of the medical profession, intelligent men who might be expected to set an example, there appears to be a very faint conception of the fact that we are engaged in a struggle for our very existence. The Council of the Royal Society of Medicine, however, is not perturbed, the Council Club holds its dinner, and a number of the sections continue to hold their meetings, at which papers are read and specimens are shown which, in many instances, cannot be regarded as having any bearing upon the treatment of the sick and wounded of our armies, and so furthering the progress of the war. Considerable sums of money are spent also in issuing the Transactions of the Society containing these papers, most of which are never read.

As a further example of waste by members of the medical profession, I may instance the issue, recently, of the List of Fellows and Members of the Royal College of Physicians of London, forwarded, I believe, to every Fellow. This book of some 400 pages is made up mainly of a list of names and addresses, information all contained in the Medical Directory. I imagine the majority of the Fellows consign it to the waste-paper basket at once. How the authorities of the College can countenance such an expenditure in paper and printing at the present time I cannot imagine.

I am, Sir, yours faithfully,

A FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND OF THE ROYAL SOCIETY OF MEDICINE.

Feb. 20th, 1917.

SPIROCHÆTAL JAUNDICE.

To the Editor of THE LANCET.

SIR,—It is satisfactory to learn from Dr. Frederick Taylor's letter in your issue of Feb. 10th that the Royal College of Physicians' Committee on the Nomenclature of Diseases is prepared to discard the name Weil's disease for the form of infective jaundice which is caused by infection with a specific spirochæte. Dr. Taylor prefers the more cumbersome name of spirochætosis-icterohaemorrhagica to spirochætal jaundice because jaundice may occur in other spirochætal diseases, such as syphilis and relapsing fever; but the same argument may be used against the longer names, as haemorrhages are certainly as common as jaundice in syphilis and are not very rare in relapsing fever. On the other hand, jaundice is the most characteristic symptom of this spirochætal infection, but it is very rare in syphilis, and was not present in a single one of the six cases of relapsing fever I saw in Salonika. As the names syphilis and relapsing fever are so well established, I do not think there can be much fear that the name spirochætal jaundice would lead to confusion with the jaundice due to these diseases.

Lastly, the inappropriate terms English disease for rickets and German measles for rubella hardly encourage further attempts in this direction, especially as it is impossible, as Dr. Taylor points out, to distinguish between the claims

of France and Japan in deciding between "S. gallica" and "S. japonica." I am inclined to think, therefore, that no more accurate or convenient name than spirochaetal jaundice is likely to be found.—I am, Sir, yours faithfully,

Netley, Feb. 11th, 1917.

ARTHUR F. HURST.

### THE DATE OF WEANING.

*To the Editor of THE LANCET.*

SIR.—The Health Society of the Borough of St. Marylebone, of which the medical officer of health is chairman, has recently circulated a copy of certain recommendations which it has addressed to its borough council with the suggestion that a similar appeal may be sent to other borough councils "to strengthen the position." The committee's appeal is concerned primarily with the effects produced by the present costliness of cow's milk, and contains the following words:—

The medical officers of the infant consultations in St. Marylebone report that the work is failing short of success because their advice as to feeding cannot be carried out owing to the high price of milk. In many cases the baby, when it is weaned, whether early or at 9 months, goes short of milk and in consequence loses weight or at best puts on 1 or 2 oz. a week—where a healthy baby makes an average of 6. Often the mother does not feel justified in weaning at the proper time, as she sees no prospect of being able to afford the quart of milk a day (3s. 6d. a week) which the baby should have. So she continues to nurse the baby long beyond nine months to the detriment of her own health and that of the baby. .... Unless steps can be taken to enable the mothers to obtain milk at a lower price, the infant mortality rate is likely to be higher next year.

It is impossible not to be in sympathy with the spirit of this appeal, nor to regret the very real hardship which the high price of cow's milk entails to many poor families and weakly infants. But the particular form of these recommendations scarcely commands the same assent. In the first place, it is by no means clear whether the rates of gain in weight quoted are intended to apply to the early months of the first year or to those after the ninth month, and in either case for how long they should be maintained. At the rate of 6 oz. a week a child would gain 19½ lb. in a year. This is certainly above the average for the first year of life, and would be grossly pathological for the second. For the latter period 2 oz. a week (6½ lb. a year) is much nearer the normal. The medical officers, moreover, employ a common contradiction in terms when they urge that a child should be "weaned" at the age of 9 months, and in the same sentence declare that a quart of milk must still be included in the daily diet. The word "wean" should imply that the child can do without milk, not that a transference from one kind of milk to another takes place. Either 9 months is too early an age at which to recommend weaning in this sense; or, if it is the "proper" time, the child does not need a quart of cow's milk daily. Both statements cannot be scientifically correct.

I would respectfully submit that this needs wider recognition. It is not, Sir, merely an etymological quibble, but a point which very vitally concerns infants, and particularly those of the class of woman attending schools for mothers and similar institutions. The practice of continuing to nurse a child beyond the age of 9 months is extremely common. But in view of the stern moral denunciation which its mention frequently receives from the medical and nursing professions, women are most reluctant to admit that after this age their children still obtain breast-milk. As the result of a large number of inquiries and observations in cases where a longer period of nursing is customary, I have been quite unable to ascertain that a healthy woman suffers thereby any decline in strength. Evidence of any actual harm to the child from continuing to take the breast is equally difficult to obtain, so long as allowance is made for the very frequent mistakes in choosing food to supplement the milk about this age. From a biological point of view, this is so exactly what might have been expected that it seems desirable to take exception to the statement of the medical officers quoted above. For if it means anything at all, it means there is something in breast milk which after nine months of lactation is inherently harmful to the child, and that the act of suckling is at the same time necessarily detrimental to the woman. It is, I believe, extremely important to qualify any such assertion by explaining that it only applies to special cases where the mother is not healthy or the child is delicate. For such cases it would be a most excellent achievement to obtain special facilities for a supply of clean milk at cheap rates.

In support of its views the committee states that it has forwarded to the borough council a list of a "few cases which have been very carefully investigated and which are typical of a very large number of those attending schools for mothers." Most medical officers of such schools could, unhappily, do the same. But there would be no difficulty in collecting from another borough of London, no more favourably situated than St. Marylebone, a large body of evidence to demonstrate the point I am at pains to emphasise—namely, that many children of the poor classes are able to maintain a perfectly satisfactory rate of gain in weight after 9 months of age, and are yet practically independent of cow's milk as food, except in so far as it is used as a convenience in cooking. Indeed, were the price of cow's milk to be lowered to a point at which it was possible for these recommendations to come into force, and were every child to start consuming a quart daily after the age of 9 months, one is tempted to wonder whether a serious rise in the death-rate would not follow automatically; the very point this Health Society is anxious to prevent. Where, also, are the cows coming from to supply such a colossal demand?

I am, Sir, yours faithfully,

Gray's Inn, W.C., Feb. 21st, 1917.

HAROLD WALLER.

### SURGEON-PROBATIONERS.

*To the Editor of THE LANCET.*

SIR.—Surgeon-General Rolleston, R.N., in his remarks on the medical personnel of the Royal Navy (*THE LANCET*, Feb. 17th, p. 255) states that surgeon-probationers, R.N.V.R., were appointed after mobilisation. Reference to a Navy List of July, 1915, shows that the first appointment to a commission as above was made on April 22nd, 1914, and that seven appointments were made before mobilisation. I think it is due to the Director-General of the Navy that this fact should be known, as it shows that the arrangements for the utilisation of the services of medical students were thought out in peace-time.

I am, Sir, yours faithfully,

P. CALDWELL SMITH,

London, Feb. 17th, 1917.

Lieutenant-Colonel, R.A.M.C., T.

### THE PLACE OF SANATORIUM TREATMENT IN TUBERCULOSIS.

*To the Editor of THE LANCET.*

SIR.—In the leading article on Tuberculosis and the War in your issue of to-day's date, you give prominence to Dr. D. Dunbar's statement as to the relative ineffectiveness of sanatorium treatment at Aysgarth, and go on to suggest that, as far as the chronic consumptive is concerned, residence in a sanatorium is not necessarily even the best form of treatment. It would be highly unfortunate if these observations should unwittingly foster the idea that sanatorium treatment has been a failure.

In the first place, such figures as Dr. Dunbar's are quite meaningless in the absence of various data—e.g., methods of selection, milieu, duration of treatment, &c., while, even if they were quite beyond criticism, it would be extremely unfair to saddle the sanatorium with blame which could more justly be imputed to after-conditions. Without any desire to exaggerate the rôle of the sanatorium or to belittle that of the dispensaries, I should like to lay emphasis on the fact that for *all* forms of phthisis the one is quite as essential as the other. It is probably true that, as modern research suggests, many latent-active cases would get well of themselves without either sanatorium or dispensary treatment (particularly the so-called abortive cases described by Bard); but it is equally true that for all cases existing on lower planes of resistance than these sanatorium treatment for at least one period, if not for several distinct periods, is absolutely essential. Moreover, in laying emphasis on the prohibitive cost of housing, even for a time, the chronic consumptive, one is apt to ignore the direct return to the State in the form of increased working capacity over astonishingly long periods, to say nothing of educative value, opportunities for administering tuberculin under observation, &c. It is not suggested by Dr. Dunbar that dispensary methods would have increased his percentage of permanent cures; and there are few public authorities would have the courage to pursue the reactionary course

of excluding chronic cases from sanatorium treatment even if the 5 per cent. for whom (according to Dr. Dunbar) a cure could be predicted would be found prepared to acquiesce in their exclusion. Finally, where there is a proper organisation of sanatorium, dispensary, and hospital treatment, together with an efficient system of examination and diagnosis (as, for instance, in Birmingham, where the tuberculosis scheme is probably a model), it will be found that the after-history records of chronic consumptives treated in sanatoria are infinitely better than those quoted by Dr. Dunbar.

If one might suggest any alterations in the present system the existing control by Insurance Committees should be abolished in favour of organisation by health departments, and the inefficient and often entirely mythical system of domiciliary treatment should be swept away; in place of the latter the dispensary system should be amplified by the appointment of a visiting staff, and institutions should be multiplied which would be available for the proper diagnosis of undetermined cases. To contemplate running tuberculosis schemes mainly on a dispensary system is, in a sense, to put the cart before the horse, if not actually to decapitate that useful animal.

I am, Sir, yours faithfully,

EDWARD G. GLOVER, M.D. Glasg.,

Medical Superintendent, Salterley Grange Sanatorium,  
Feb. 17th, 1917.

### PNEUMATIC TOURNIQUETS.

To the Editor of THE LANCET.

SIR.—The recent letters on this subject would suggest that pneumatic tourniquets are something new, whereas they have been used extensively for several years. In THE LANCET of Jan. 25th, 1913, I illustrated a pneumatic tourniquet which I had used for several months and therein described its uses, its advantages, and some practical points which I had learnt in employing it. I have seen no reason to have it altered from the original model, and the makers, Messrs. Montague, 69, New Bond-street, tell me they have sold a large number, and receive frequently inquiries about them.

I am, Sir, yours faithfully,

R. H. JOCELYN SWAN, M.S. Lond., F.R.C.S. Eng.,

Major, R.A.M.C.; Senior Surgeon, Royal Herbert Hospital, Woolwich, &c.  
Wimpole-street, W., Feb. 17th, 1917.

### THE DRESSING OF BURNS WITH PARAFFIN WAX.

To the Editor of THE LANCET.

SIR.—In an annotation under the above heading in your issue of Feb. 17th the use of Dr. Barthe de Sandfort's "ambrine" is mentioned as being applied for use in the Navy by the instructions of Sir Arthur May.

It is stated that: "As, however, the preparation is a secret one controlled by a company in Paris, the treatment is not as readily accessible as some of our correspondents desire."

"Ambrane" is composed of specially prepared paraffin wax with 5 per cent. of oleum succini, and will now be readily obtainable, the representation for Great Britain, &c., being in the hands of—Yours faithfully,

THE ANGLO-FRENCH DRUG CO., LTD.

Gamage Buildings, Holborn, London, E.C., Feb. 17th, 1917.

**DONATIONS AND BEQUESTS.**—By will the late Mr. Edward Hinkley, of Southport, bequeathed £1000 each to the Southport and Birkdale District Nursing Society, the Leicester Infirmary, Southport Infirmary, £500 each to the Southport Children's Sanatorium, Leicester Institute for the Blind, Leicester Institute for the Deaf and Dumb, Southport Institute for the Deaf and Dumb, and the Homoeopathic Dispensary, Southport.—The late Mr. J. Holmes, of Bradford, left £500 to the Bradford Royal Infirmary and the residue of his estate to the Bradford Eye and Ear Hospital and the Bradford Children's Hospital.—By the will of the late Mr. Alfred Ewin, of Southend, the testator has bequeathed £1000 each to the City of London Hospital, Victoria Park, and the Queen Alexandra Hospital, Hackney-road; £600 to the Southend Victoria Hospital and Nursing Home for a "Ewin" bed, and £300 for a children's cot to be called after him, and £200 to the Adelaide Dispensary, Bethnal Green.

### Medical News.

UNIVERSITY OF BRISTOL.—At examinations held recently the following candidates were successful:

FINAL EXAMINATION FOR THE DEGREES OF M.B., CH.B.

Part I. only.—Daniel Gingell Cosham.

DIPLOMA IN PUBLIC HEALTH.

Pass.—James Francis Blackett.

Part II., completing examination.—John Maurice Harper.

Part I. only.—Isaac Bernard Barclay.

HEALTH INSURANCE FINANCE IN LONDON.—A deputation from the London Insurance Committee was recently received by Sir Edwin Cornwall, M.P., chairman of the National Health Insurance Joint Committee, which laid before him the financial position of National Insurance in London in plain terms. The carrying out of the work of the London Insurance Committee upon the allowance made by the Treasury was stated to be impossible, the deficit was fixed at £20,000, and the probability of a levy having to be made upon the insured population of the County of London, if no further support from the Government should be forthcoming, was spoken of. Sir Edward Smith, the spokesman of the deputation, added that public men were not prepared to give up their time to the administration of National Insurance unless the money necessary for their purpose was forthcoming, and that those associated with him would prefer to resign their positions rather than continue attempting the work assigned to them upon an insufficient income. Sir Edwin Cornwall accorded a sympathetic reply and spoke of the request made, as being reasonable.

ROYAL MEDICAL BENEVOLENT FUND GUILD.—The annual meeting of the Guild was held on Feb. 16th at 11, Chandos-street, W., when Lady Tweedy presided and read the report of Council for the preceding year. The report of the Father Christmas branch was read by Miss Gladys Edwards, honorary treasurer. The sub-reports of the Case Committee and the Clothes Committee were read by the respective chairmen, Mrs. Liveing and Mrs. Furnival. In the unavoidable absence of the honorary treasurer, Mrs. Scharlieb, Lady Fripp submitted the financial statement. Dowager Lady Broadbent's resignation of the presidency of the Guild was accepted, and the nomination of Lady Bradford as President was confirmed. The need of new secretaries was emphasised by Lady Tweedy's statement that the Guild received applications for help from such widely scattered districts as the Shetland Isles, Wales, and Cornwall. She was glad to say that with the increase of applicants pleading for help the charity was also increasingly supported, and in two cases the Guild was benefited by gifts from the trustees of funds left for charitable purposes. This marks the beginning of an important source of help.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on Feb. 15th, with Sir Francis H. Champneys in the chair.—Further correspondence was considered with reference to a candidate for examination who was stated by the approved midwife in whose house she was residing to have taken a variety of drugs and stimulants during the week preceding an examination, and in particular during the morning of the first day of the examination. The Board directed that the statement of the candidate be referred for comment to the approved midwife in whose house the taking of drugs and stimulants is alleged to have occurred.—Further correspondence was considered with reference to a candidate for examination who had tendered a certificate of birth which had been falsified. The Board decided that the candidate having now furnished the Board with an explanation of the circumstances attending the falsification of her birth certificate, and having tendered a fresh and unaltered birth certificate, be admitted to examination.—A letter was considered from the Acting Registrar of the General Medical Council conveying the request of the President that the Board would forward to the local supervising authorities (a) a copy of a circular letter addressed by the Council to all the registered medical practitioners in England and Wales, calling their attention to the provisions of the Midwives Act, 1902, which prohibit any women not being certified under the Act from attending women in childbirth habitually and for gain otherwise than under the direction of a qualified medical practitioner; (b) a copy of a warning notice issued by the Council, pointing out that any registered medical practitioner proved to have been guilty of "covering" an uncertified woman will be liable to have his name erased from the Medical Register. The secretary reported that the Local Government Board have expressed a desire to forward from their office the circular letter and the warning notice to the various local supervising authorities, and that the General Medical Council have

agreed to this being done. It was decided that the Central Midwives Board has no objection to the Local Government Board distributing the circular letter and warning notice of the General Medical Council as suggested by the Local Government Board.—A letter was considered reporting the conviction of an uncertified woman for a breach of Section 1 (2) of the Midwives Act, 1902, and requesting the Board to consider the conduct and action in connexion with this case of a medical practitioner. The Board resolved that the papers in the case be forwarded to the General Medical Council with a request that they will take such action in the matter as may seem fit to them, and that if so desired the Board will undertake to appear as prosecutors in the case.—A letter was also considered reporting the prosecution of an uncertified woman for a breach of Section 1 (2) of the Midwives Act, 1902, and of a registered medical practitioner for aiding and abetting her, and requesting the Board to consider his conduct and action in connexion with the case.

**CENTENARIAN.**—Mrs. Mary Ann Brooks celebrated the 101st anniversary of her birthday at King's Lynn on Feb. 19th.

**THE annual meeting of the Mental After-Care Association** will be held at the house of Sir Robert Armstrong-Jones, 9, Bramham-gardens, South Kensington, London, S.W., the Lord Mayor of London presiding. The meeting is open to all interested.

## Parliamentary Intelligence.

### NOTES ON CURRENT TOPICS.

#### *Criminal Law Amendment Bill.*

**THE Criminal Law Amendment Bill**, which has been introduced in the House of Commons by the Home Secretary "to make further provision with respect to the punishment of sexual offences and the prevention of indecent advertisements and matters connected therewith," has been printed. It was read a second time on Monday, Feb. 19th. The Bill, which is an important one, makes it an offence to communicate knowingly venereal disease, extends the Indecent Advertisements Act with a view to suppress the advertisement of the "quack" treatment of venereal diseases, and imposes increased penalties for the offences of soliciting and the maintenance of houses of ill-fame.

Clause 1 deals with the punishment of acts of indecency with girls under 16. It runs:—

(1) Any male person of the age of 16 years or over who commits an act of indecency with a girl under the age of 16 years shall be liable on conviction on indictment to imprisonment with or without hard labour for a term not exceeding two years, or on summary conviction to imprisonment with or without hard labour for a term not exceeding six months; and it shall be no defence to a charge under this section to prove that the girl consented to the act of indecency.

(2) No prosecution shall be commenced for an offence under this section more than six months after the commission of the offence.

(3) If upon the trial of any indictment for rape or for an indecent assault, or for an offence under sections 4 or 5 of the Criminal Law Amendment Act, 1885 (in this Act referred to as the principal A.), or under the Punishment of Incest Act, 1908, the jury are not satisfied that the defendant is guilty of the offence charged but are satisfied that he is guilty of an offence under this section, they may acquit the defendant of the offence charged and find him guilty of an offence under this section. In every such case the defendant shall be liable to be punished as if he had been convicted upon an indictment for the offence of which he is so found guilty.

#### *Communication of Venereal Disease.*

Clause 2 imposes a penalty on a person suffering from venereal disease who has sexual intercourse with another person. Its terms are:—

(1) A person who is suffering from venereal disease in a communicable form shall not have sexual intercourse with any other person or invite any other person to have such sexual intercourse.

(2) If any person acts in contravention of this section, that person shall be liable on conviction on indictment to imprisonment with or without hard labour for a term not exceeding two years, or on summary conviction to imprisonment with or without hard labour for a term not exceeding six months. Provided that a person shall not be convicted under this section if that person proves that he or she had reasonable grounds to believe that he or she was free from venereal disease at the time the alleged offence was committed.

(3) Where any person is convicted of any of the offences mentioned in the Schedule to this Act [these are offences against this measure and certain specified offences against the person] the court may, if they think fit, for the purpose of ascertaining whether that person is suffering from venereal disease in a communicable form order that person to submit to such medical examination and tests as may be requisite for that purpose. If the person is a female, the examination and tests shall be conducted, if she so desires, by a female doctor.

(4) Where a person has within three months before the commission of any alleged offence under this section received a written notice, either on an examination ordered under this section or while under compulsory detention in any prison or other institution, from a duly qualified medical practitioner that he or she is suffering from venereal disease in a communicable form that person shall be deemed to have

been so suffering at the time when the alleged offence was committed, unless the contrary is proved.

(5) An offence under this section shall be deemed to be an offence to which Section 29 of the Larceny Act, 1916 (which relates to the demanding of money, &c., with menaces), applies.

(6) In this section the expression "venereal disease" means syphilis, gonorrhœa, or soft chancre, or any disease of the genito-urinary organs which may reasonably be suspected to be venereal disease.

Clause 3 lays down that cause to believe that a girl was of or above the age of 16 shall not be a defence to a charge under Sections 5 or 6 of the Criminal Law Amendment Act. Clauses 4 and 5 relate to proposals to increase penalties for keeping brothels, and Clause 6 amends the penalty for soliciting or loitering for the purposes of prostitution.

#### *Indecent Advertisements.*

Clause 7 extends the Indecent Advertisements Act and is in the following terms:—

(1) The Indecent Advertisements Act, 1889, shall be extended as follows: (a) A person who publishes by way of advertisement, or causes to be published, any picture or printed or written matter which is of an indecent or obscene nature, shall be guilty of an offence under Section 3 of that Act and punishable accordingly; (b) a person who gives or delivers to any other person any such picture or printed matter or written matter with intent that the same should be published by way of advertisement, shall be guilty of an offence under Section 4 of that Act and punishable accordingly; (c) the maximum penalties under Sections 3 and 4 of that Act shall be £100, and six months' imprisonment instead of 40s. and one month's imprisonment and £5 and three months' imprisonment respectively, and those sections shall have effect accordingly; (d) The following section shall be substituted for Section 5:—"Any advertisement relating to syphilis, gonorrhœa, nervous debility, or other complaint or infirmity arising from or relating to sexual intercourse, and any advertisement which suggests directly or indirectly, the use or taking of any appliance, drug, substance, or thing, for the purpose of procuring miscarriage or abortion, or which suggests, directly or indirectly, that any premises are or can be used for immoral purposes, shall be deemed to be printed or written matter of an indecent nature within the meaning of Section 3 of this Act."

(2) Nothing in the Indecent Advertisements Act, 1889, as amended by this Act shall apply to any advertisement by any local or public authority, or to any advertisement published in any *bond-fide* medical or pharmaceutical publication or pharmaceutical trade list; and a person charged under that Act as so amended with publishing an advertisement, if he is not himself the advertiser, shall not be convicted if he proves that he did not know, and had no reasonable ground for suspecting, that the advertisement was of such a character as to make the publication thereof an offence.

The remaining clauses deal with procedure and with the application of the measure to Scotland and Ireland.

#### *The Second Reading.*

The HOME SECRETARY, in moving the second reading of the Bill, said that a strong case existed for such a measure. The evils which were aimed at were patent to all, and the need for a remedy was urgent. He was quite ready to think that this country was no worse than, and, indeed, it might be better than, many other countries. He had aimed at confining the measure to proposals which would receive general assent and would, he hoped, be quickly passed into law. The right honourable gentleman proceeded to explain the terms of the Bill. With reference to Clause 2, which dealt with the subject of venereal diseases, he believed that matter was of real importance to the future of the race, and by the admirable report of the Royal Commission on Venereal Disease it had been brought into the region where action might be taken. Of the many recommendations of that Commission perhaps the most important dealt with questions of diagnosis and of treatment, and with the provision of institutions assisted by the local authorities. These matters were in the province of the Local Government Board, which had taken vigorous action in that direction. The suggestion that unqualified practice should be restricted was closely allied with the question of treatment. That subject was not a matter for the Home Office, but it was being considered by the President of the Local Government Board with a view to legislation along that line. There remained matters which must be dealt with, if at all, by amendments of the criminal law, and after consultation with the President of the Local Government Board and his advisers he had included in the Bill two provisions relating to venereal disease. One of these provided that "a person who is suffering from venereal disease in a communicable form shall not have sexual intercourse with any other person or invite any other person to have such sexual intercourse." He thought that a person of either sex who had the misfortune to suffer from one of these terribly contagious complaints ought not to be allowed to act so that the disease was likely to be communicated to others and perhaps passed on to future generations. Therefore he proposed to make that in itself an offence. When this disease was so terribly contagious its communication ought to be prevented. He was conscious that there might be difficulties in bringing the offence home to those who were guilty of it. Special provisions had been inserted which would operate in certain cases. It was provided that a person convicted of certain offences which were of a sexual character might be examined by a medical man in order to ascertain whether he

or she was suffering from one of these diseases. The doctor in the case of a female prisoner would, if desired, be a female doctor. Then the doctor who made the examination might, if the person was suffering from venereal disease, give a written notice to that effect, so that the person could not afterwards say that he or she had had no notice of the disease. He did not think that anyone could complain of an arrangement of that kind. The other matter relating to venereal disease was contained in Clause 7, which dealt with the Indecent Advertisements Act, 1889. That Act provided that advertisements for the cure of venereal diseases should be deemed indecent, but it omitted to deal with advertisements in newspapers. It was proposed to extend the Act to advertisements in newspapers. It was also desired to extend it to advertisements of means for procuring abortion, or suggesting that premises could be used for immoral purposes.

Mr. HERBERT SAMUEL (the late Home Secretary) said that he was convinced that the Bill would do much to mitigate the havoc which was wrought by venereal diseases and the scandals of child prostitution. He observed that he was not in favour of the compulsory notification of venereal disease. It was strange that the law had not hitherto made it an offence for a person with full knowledge of his condition to infect another person with venereal disease.

In the course of the subsequent debate Sir HENRY CRAIK insisted on the urgency of the measure. Several Members criticised some of the provisions in the Bill, which was read a second time. It will be considered in Committee of the whole House.

#### HOUSE OF COMMONS.

WEDNESDAY, FEB. 14TH.

##### *Operations on Soldiers.*

Mr. KING asked the Under Secretary for War whether orders had been given to surgeons of London hospitals not to undertake any operations on soldiers under their charge for diseases originating before they were wounded if the treatment of such cases would delay them from rejoining any longer than would be necessary for recovery from their wounds.—Mr. MACPHERSON answered: The criterion in this matter is fitness for military service, and no instructions have been issued to prevent surgeons performing operations which are necessary for the cure of any disability which unfit a man for military service.

##### *Medical Men's Cars and the Speed Limit.*

Mr. CHANCELLOR asked the Home Secretary whether, in view of the shortage of doctors which now necessitated their journeying considerable distances to visit patients, he would consider the advisability of the speed limits for motor-cars being waived so as to reduce the time spent en route; and whether, in view of the restricted lighting and the difficulties of transit at night, in order to facilitate doctors when visiting urgent cases, they might be permitted to use unobscured headlights on their motor-cars.—Sir G. CAVE wrote in reply: I have no authority to waive the speed limit for motor-cars. In framing the orders as to lights on vehicles, special regard has been paid to the requirements of doctors and others who have occasion to travel by road at night. The orders now in force allow the use of sufficient light for safe driving at ordinary speed, and I do not see my way to authorise the use of unrestricted headlights as the honourable Member suggests.

THURSDAY, FEB. 15TH.

##### *Hospital Accommodation in Mesopotamia.*

Answering Sir J. JARDINE, Mr. MACPHERSON said that the situation as to supplies and transport in Mesopotamia was now satisfactory. Hospital accommodation was being provided at Nasiriyah, and as soon as it was ready nurses would no doubt be sent there.

MONDAY, FEB. 19TH.

##### *Medical Treatment of Soldiers' Widows.*

In answer to Mr. MURRAY MACDONALD, Mr. BARNES (Minister of Pensions) wrote: Resolutions have been received from several Insurance Committees suggesting that public provision should be made for the medical treatment of widows and orphans of sailors and soldiers through the medium of the committees. The matter is receiving very careful consideration.

##### *Discharged Soldiers and Tuberculosis Treatment.*

Sir E. CORNWALL (representing the Insurance Commission), in reply to Mr. HOGGE, said: Under special arrangements made by the various Insurance Commissioners with the Admiralty and the War Office beds have been provided for nearly 5000 discharged soldiers and sailors suffering from tuberculosis. Insurance Committees have, in addition, provided beds in the ordinary arrangement for a considerable number of discharged men, but I have no information as to the exact number.

##### *Derbyshire Insurance Committee.*

Mr. THOMAS RICHARDSON asked the Representative of the National Insurance Commissioners whether his attention had been called to the fact that the Derbyshire Insurance Committee proposed to charge the practitioners concerned with the estimated cost of medical service subcommittee inquiries; and whether he would take the necessary steps to prevent the Derbyshire or any other Insurance Committee from taking such action, which was giving rise in the medical profession to dissatisfaction with the administration of medical benefit.—Sir E. CORNWALL replied: My attention has not been drawn to the matter to which my honourable friend refers, but in the event of any dispute arising between Insurance Committees and the practitioners the latter have the right of appeal to the Commissioners, who would thereupon deal with the question.

TUESDAY, FEB. 20TH.

##### *"Manipulative" Surgery.*

Mr. MACVEAGH asked the Under Secretary for War whether the War Office was willing to appoint immediately a committee composed of men of high attainments but not connected with the medical profession, in order to inquire into the question of utilising for the alleviation of the sufferings of wounded soldiers the services of experts in manipulative surgery who did not hold medical degrees.—Mr. MACPHERSON replied: No, sir.

Mr. MACVEAGH: Why do the War Office object to the appointment of an independent committee?—Mr. MACPHERSON: It is a very doubtful proposition to suggest that non-technical men should be put to deal with a technical subject.

Mr. SWIFT MACNEILL: Are the Government prepared to allow men to suffer in the interest of professional trades unionism?—Mr. MACPHERSON: I must protest against that. Nothing can be more admirable during the whole course of the war than the skill, judgment, and effectiveness displayed by the medical profession.

Sir WILLIAM COLLINS: Whilst not excluding the investigation of any line of treatment from whatever source it may be suggested, will the honourable gentleman have regard to the risks as well as the advantages of uncertified practitioners?—Mr. MACPHERSON: Certainly.

In reply to two questions as to treatment in two instances, Mr. MACPHERSON said that he had no information on them.

Mr. MACVEAGH asked whether the honourable gentleman was aware that the medical profession in France was availing itself of the services of experts in manipulative surgery for the treatment of wounded soldiers; and whether he could state on what grounds the War Office in this country refused to allow a similar dilution of labour.—Mr. MACPHERSON answered: I have no information on the first part of the question. In regard to the second part of the question, apart from other objections, it is the case that under the terms of the Medical Act, 1858, it is not possible to employ as surgeons in the military service any person not registered under that Act.

Mr. MACVEAGH asked whether the honourable gentleman was aware of the statement that manipulative surgery was being used in France.—Mr. MACPHERSON: It would be much better that these things should be discussed in debate rather than by question and answer. I can tell the honourable Member that not only have we the finest doctors and surgeons, but we have also the finest hospitals where the men are treated.

## Appointments.

*Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

- HUTTON, A., M.B., Ch.B., Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Wartie District of the County of Aberdeen.  
 LEITCH, A., M.D., R.U.I., Medical Officer and Medical Officer of Health to the Castlederg Dispensary District, County Tyrone, pro tem.  
 STYAN, T. G., M.D. Cantab., Temporary Medical Officer of Health for Bamsgate.  
 TOBIN, R. F., F.R.C.S. Irel., Inspector for Ireland under the Vivisection Act.

ST. THOMAS'S HOSPITAL.—Casualty Officers and Resident Anesthetists: BLAMPIED, H. J., M.R.C.S., L.R.C.P., CHURCHER, D. G., M.R.C.S., L.R.C.P., ORME, E. S., B.A., M.R.C.S., L.R.C.P., and WARE, S. A. T., M.R.C.S., L.R.C.P. Resident House Physicians: BESWICK, W. T., B.A. Cantab., MAVROGORDATO, A., M.A. Oxon., M.R.C.S., L.R.C.P., MILES, M. W. H., M.R.C.S., L.R.C.P., and WOOLRICH, W. G., B.A. Cantab. Resident House Surgeons: MOORE, L. C., JENNINGS, H. C., M.R.C.S., L.R.C.P., BOYFIELD, G. W. J., and SAI, P., M.R.C.S., L.R.C.P. House Surgeon to Block 8: BLUETT, D. C., M.R.C.S., L.R.C.P. Obstetric House Physician: HARRIS, J. R., M.R.C.S., L.R.C.P. Ophthalmic House Surgeon: MARRIOTT, W. Clinical Assistants: DAVIS, F. G. S., and CIEH, Y. J., M.R.C.S., L.R.C.P.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor:*

APPLECROSS, PARISH OF, ROSS-SHIRE.—Medical Officer, &c., for Torridon District. Estimated emoluments £350 per annum.  
 ASHTON-UNDER-LYME, LANCS., DISTRICT INFIRMARY AND CHILDREN'S HOSPITAL.—Assistant House Surgeon. Salary £160 per annum, with usual emoluments.  
 BATH, EASTERN DISPENSARY.—Resident Medical Officer. Salary £140 per annum, with furnished rooms, &c.  
 BIRKENHEAD UNION INFIRMARY.—Junior Female Resident Assistant Medical Officer. Salary at rate of £300 per annum, with board, &c.  
 BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £250 per annum, with furnished rooms, &c.  
 BIRMINGHAM AND MIDLAND HOSPITAL.—Female House Surgeon. Salary £200 per annum.  
 BRISTOL ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.  
 BURY INFIRMARY.—Junior House Surgeon. Salary £150 per annum, with board, &c.

CARDIFF, KING EDWARD VII'S.—Two House Surgeons for six months. Salary at rate of £175 per annum, with board, &c.  
 DERBYSHIRE, DEVONSHIRE HOSPITAL, BUXTON.—Assistant House Physician. Salary £100 per annum, with board, &c.  
 DUNDEE DISTRICT ASYLUM.—Assistant Resident Medical Officer. Salary £300 per annum, with board, &c.  
 DUNDEE MATERNITY AND CHILD WELFARE SCHEME.—Medical Practitioner (Female). Salary £350 per annum.  
 EVELINA HOSPITAL FOR CHILDREN, Southwark, S.E.—House Physician. Salary at rate of £160 per annum, with board, &c.  
 FAREHAM, HANTS COUNTY ASYLUM.—Temporary Assistant Medical Officer. Salary 6 guineas a week, with board, &c.  
 GREAT YARMOUTH HOSPITAL.—House Surgeon, unmarried. Salary £200 per annum, with board, &c.  
 GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £200 per annum, with board, &c.  
 HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—House Surgeon and Assistant Casualty Medical Officer. Salary at rate of £50 per annum, with board, &c.  
 LONDON COUNTY COUNCIL.—Two Female Medical Inspectors (unmarried or widows) in the Public Health Department. Salary £300 a year.

MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Senior House Surgeon. Salary £250 to £300 per annum.  
 MANCHESTER, ABERGELLE SANATORIUM.—Temporary Medical Superintendent. Salary £300 per annum, &c.  
 MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road.—Female House Surgeon. Salary £120 per annum, with board, &c.  
 NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—Junior House Physician. Salary £150 per annum, with board, &c.  
 PORTSMOUTH ROYAL HOSPITAL.—House Surgeon for six months. Salary £250 per annum, with board, &c.  
 PRIVATE FIRST LINE MILITARY HOSPITAL, near London.—Senior Lady House Surgeon. Salary £300 per annum, with board, &c.  
 QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford.—House Surgeon.  
 ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Third House Surgeon. Salary at rate of £50 per annum, with board, &c.  
 SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician and Junior House Surgeon. Salaries £150 and £120 per annum respectively, with board, &c.  
 SUSSEX HILL ROYAL INFIRMARY.—Female House Surgeons. Salaries—Senior, £250; Junior, £200 per annum, with board, &c.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—Senior Resident Medical Officer. Salary £250 per annum, with board, &c.

WEST-END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W.—House Physician. Salary £250 per annum, with board, &c.  
 WEST HAM UNION SICK HOME, 95, Forest-lane, Forest Gate, E.—Resident Assistant Medical Officer. Salary £300 per annum, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Morriston, Woodstock, Wansford, Helston, and Clonakilty.

## Births, Marriages, and Deaths.

### BIRTHS.

BUNBURY.—On Feb. 14th, at "Moorlands," Mullion, the wife of E. G. Bunbury, M.R.C.S., L.R.C.P., of a daughter.

HEWITT.—On Feb. 11th, at Nottingham-place, W., the wife of Lieutenant R. C. Hewitt, R.A.M.C., of a daughter.

HUGHES.—On Feb. 13th, at Barnsley Hall, Bromsgrove, Worcester-shire, to Dr. and Mrs. Percy T. Hughes—a son.

KIRKNESS.—On Feb. 10th, at The King's Service Home, Sonthea, the wife of W. R. Kirkness, M.R.C.S., L.R.C.P., "Montrose," Portsmouth, of a daughter.

MCMULLEN.—On Feb. 13th, at Temple-avenue, Golders-green, the wife of W. Halliburton McMullen, F.R.C.S., of a son.

WILLIAMSON.—On Feb. 19th, at "Kingamoor," Sutton, Surrey, to Surgeon David J. Williamson, M.D., R.N.V.R., and Mrs. Williamson (*née* Joan Bonford)—a son.

### MARRIAGES.

BUCKLEY—BRINDEJONT.—On Feb. 17th, at the Church of St. Ferdinand des Ver. es, Paris, Captain Leonard Buckley, R.A.M.C., to Suzanne, only daughter of Prosper Brin de Jont, of Paris.

CRESSY—GRIESBACH.—On Feb. 19th, at the Parish Church, Alderton (Glos.), Charles James Cressy, M.R.C.S., L.R.C.P., to Julia, daughter of the late Sydney Griesbach, M.R.C.S., L.R.C.P., of Garforth, Leeds.

DE NYSEN—EDWARDS.—On Feb. 15th, at the Parish Church, Haleworth, P. J. de NySEN, M.R.C.S. Eng., L.R.C.P. Lond., to Rose Edwards, of Holton Lodge, third daughter of the late John Cooper Forster, President of the Royal College of Surgeons.

MC CALL—PRITCHARD.—On Feb. 17th, at the Church of "Our Lady Help of Christians," Blackheath, Henry Dundas McCall, M.R.C.S., L.R.C.P., R.A.M.C., to Margaret Ruth Mary, third daughter of Mr. and Mrs. W. R. Pritchard, Glenwood, Lee.

TREHERNE—BURPEE.—On Feb. 14th, at the Parish Church, Weybridge, Captain C. W. Treherne, R.A.M.C., to Marjorie, youngest daughter of Mr. and Mrs. F. Burpee, of Vancouver, B.C.

WATSON—TEEVAN.—On Feb. 1st, at St. James's, Spanish-place, W., Colonel C. Gordon Watson, C.M.G., F.R.C.S., of 82, Harley-street, to Geraldine, daughter of the late Charles James Teevan, of Woodside Court, Croydon.

### DEATHS.

CURRIE.—On Feb. 16th, at Trinity Hall, Bungay, John Legge Currie, L.R.C.P. Lond., M.R.C.S.

FRANKLIN.—On Feb. 17th, at Westhay, East Sheen, suddenly, Surgeon-General Sir Benjamin Franklin, K.C.I.E., K.H.P., aged 72 years.

JESSOP.—On Feb. 18th, at Harley-street, of pneumonia. Walter Hamilton Hilton Jessop, M.A., M.B. Cantab., F.R.C.S., J.P., ophthalmic surgeon to St. Bartholomew's Hospital, and President of the Ophthalmological Society of the United Kingdom, in his 64th year.

LAWSON.—On Feb. 18th, at Ventnor Villas, Hove, Sussex, formerly of Holme House, Hebburn Bridge, Yorks, Joseph Lawson, B.A., M.B., T.C.D., aged 70 years.

ROXBURGH.—On Feb. 16th, suddenly, of angina pectoris, Robert Roxburgh, M.B., F.R.C.S.E., honorary physician to the Weston-super-Mare Hospital, and honorary consulting physician to the Royal West of England Sanatorium, aged 63 years.

WOODCOCK.—On Feb. 17th, at Nottingham-place, Louisa Woodcock, M.D., B.S. Lond., M.A. T.C.D., aged 51 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

### METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

## Notes, Short Comments, and Answers to Correspondents.

### MEDICAL MEN AND THE RIGHT TO REFUSE ATTENDANCE.

THE old question of the common-law medical rights of a medical practitioner to refuse to attend when summoned to visit a sick person without receiving a fee was raised at an inquest recently at York, when Dr. P. Schmidt was unjustly held by the jury to be "deserving of the severest censure in not carrying the case through." The medical man had received a fee for a previous attendance upon the deceased, a child of 6 months, but when sent for on the following day delayed going until the evening. He then recommended that the child should be taken to the county hospital, where the death took place a few minutes after the patient's admission. The fact that a second fee was not forthcoming was frankly admitted by the medical man to have been his reason for not attending when he was summoned. The report of the evidence given at the inquest by Dr. Schmidt justifies the surmise that a somewhat outspoken manner of asserting his right to ask for a fee and to refuse attendance in the absence of one may have prejudiced the medical man before the jury and may have been largely responsible for the censure passed upon him. The justice of such censure is not apparent. In refusing to attend in the absence of any prospect of remuneration a medical man exercises an undoubted right, which the public at large has recognised by instituting voluntary hospitals and dispensaries and Poor-law infirmaries for the benefit of those unable to pay for medical attendance. A medical man may, and very often does, attend poor patients without hope of reward, but the extent to which he does this is a matter which must be left to him to decide. One man having private means, or a remunerative practice, can afford to be generous in such matters where another cannot. A medical practitioner living in a poor neighbourhood would find a very large number of patients anxious to employ him and unable to pay him, if he once let it be known that his services were at the disposal of those so situated. In the same way a provision merchant in such a district who was ready to hand over his goods to those unable to pay for their purchases would soon have many customers. But neither the medical man nor the provision merchant would make a livelihood, and each has an equal right to endeavour to do so.

Probably if medical men asked the editors of their local daily and weekly papers to insert the above remarks, we would have a marked falling off in these very questionable censures by coroners and Poor-law juries.

### VITAL STATISTICS OF THE FEDERATED MALAY STATES AND THE STRAITS SETTLEMENTS.

Sir Edward Lewis Brookman, K.C.M.G., Chief Secretary to the Government of the Federated Malay States (Perak, Selangor, Negri Sembilan, and Pahang), in his report for the year 1915, just presented to Parliament, states that as the conditions relating to immigration and emigration have recently been abnormal the present population is probably considerably less than that shown by the census of 1911, viz., 1,172,336. The number of births in 1915 was 29,699 and of deaths 33,899. There were 5778 deaths of infants under one year of age and the infantile mortality rate was 194 per 1000. It is suggested by the Principal Medical Officer that without malaria the infantile death-rate would not be of great importance. The death-rate in the principal towns in 1915 was: Kuala Lumpur, 27.83 per 1000; Ipoh, 27.8 per 1000; Taiping, 33.99; and Seremban, 47.15. Malaria accounted for 44 per cent. of the total deaths. Dysentery and diarrhoea caused 3148 deaths, beri-beri 371, and pulmonary tuberculosis 1995. There was a severe outbreak of small-pox in the district of Lower Perak. Several cases also occurred in Selangor and Negri Sembilan, but only one case was reported in Pahang. Two cases of plague occurred in Perak. Venereal diseases show a distinct falling-off. The medical institutions maintained by the Government comprise 42 hospitals, 9 jail hospitals, 2 lunatic asylums, 3 leper asylums, and 15 out-door dispensaries. The number of in-patients treated during the year was 72,792 and of out-patients 204,997, both totals showing a remarkable decrease as compared with the previous year. The reports of the lady medical officers at Kuala Kangsar and Kuala Pilah show that they are doing much good work. Their services are greatly appreciated. Attempts have been made to get into touch with native midwives, but without much success. One of the lady medical officers observes that the large percentage of normal maternity cases among Malay women gives the midwives the appearance of skill which they do not possess;

and on the subject of infantile mortality she expresses the opinion that it is fever that more likely causes the high mortality than any errors in feeding.

On an estimated total population of 776,444 in the Straits Settlements, the birth-rate in 1915 was 29.25, and the death-rate 29.15 per 1000; for the European inhabitants, estimated at 8086, these ratios were 24.24 and 14.96 per 1000 respectively. The Principal Medical Officer, Dr. W. Gilmore Ellis, considers that on a different and more exact estimate of the population, according to the method of the medical officer of health of Singapore, the death-rate should be really 31.13 per 1000. The infantile mortality was 236.68 per 1000, being highest among Malays, who habitually feed their infants a few days old on boiled rice, which leads to indigestion and convulsions. Lectures on the subject are being given in the vernacular by Dr. Keun, which, it is hoped, may lead to improvement. There were 37 cases of plague (with 33 deaths) and 17 cases of cholera (with 10 deaths). Deaths from beri beri have decreased steadily from 2056 in 1911 to 1079 in 1915. At the Beri-beri Hospital, Pasir Panjang, all of the cases admitted had habitually eaten uncurled Siam rice; of the 135 discharged 9 were recovered and 113 considerably improved. At the Leper Asylum, Penang, with 411 inmates, more than 70 cases have been treated with injections of natin and Dr. Heiser's preparation of chaulmoogra oil; the results are being carefully watched, and in many instances considerable improvement (return of sensation, shrivelling up of nodules, disappearance of dermatitis) has been observed. There have been fewer admissions for ankylostomiasis (932) during 1915 than in either of the two years preceding, but owing to the paucity of health officers it has not been possible to make much progress in the eradication of the disease. Mr. Gilbert Brooke, chief health officer of Singapore, reports that the practical absence of infectious disease from all the great ports of the East is without parallel for several decades past; for five weeks from the beginning of September not a single port was in quarantine. No immigration was allowed during the first three months of the year, and for the next three months only limited immigration. Owing to the war the return pilgrimage season for Mecca had been accelerated into 1914, and no pilgrim sailings left the Straits at all for the 1915 season. A new quarantine and prevention of disease ordinance has been passed, including, among other improvements, the insistence on vaccination of unprotected immigrants from China and India, and discretionary powers for the detection and treatment of cases of infectious disease, and for their repatriation if necessary.

### KITCHENER CLUB FOR WOUNDED SOLDIERS.

THIS club for wounded soldiers has been started under theegis of the Red Cross at 8, Cambridge-gate, Regent's Park, London, N.W., and is open daily from 10 to 6. Reading and writing rooms are provided, and lunch and tea will be served free of charge.

### WOMEN SANITARY INSPECTORS AND HEALTH VISITORS' ASSOCIATION.

THE 1916-1917 handbook of the association, just issued, contains the names of the executive officers and members of committees, the rules of the association, an alphabetical list of members and associates, and the report for the session 1915-16. Several members are engaged on war service. The honorary secretary of the association is Miss O'Kell, 12, Buckingham-street, Strand, London, W.C.

### FOOD SUBSTITUTES IN GERMANY.

IT is probable that some difficulty is being experienced in those countries suffering from a shortage of food in administering the adulteration laws, inasmuch as mixtures are now allowed which were not allowed before. We have as examples in our own country the watering of spirits, the addition to wheat flour of other flours, and so forth. The opportunity, however, was sure to be one seized upon by the unscrupulous, and examples appear to have occurred in Germany of selling substitutes for the genuine article which can in no sense be regarded as supplying the necessary qualities of the comestibles so imitated.

In connexion with an exhibition of food substitutes a report has been issued by the Berlin Municipal Laboratory on the food adulterations which are at present so plentiful in Germany. It is stated that a large number of enterprising persons are devoting their time to the manufacture of food substitutes. Among these are the "bouillon cubes," which by law must contain at least 7½ per cent. of meat extract, but which actually consist of common salt together with a little colouring matter. "Powdered beef-tea," which is sold in attractive-looking small boxes, is composed of wheat-flour, common salt, a little clay, with a mere trace of meat extract. A "cheese substitute" in the form of a red powder contains 70 parts of common salt, 20 parts of powdered Hungarian pepper, a few grains of

aniseed, and some acid. Much-vaunted powders for making puddings contain coloured and flavoured potato flour, and are sold at 2s. 6d. per pound. There is even a substitute for pepper on the market. As the law has proved powerless against these fraudulent food articles, housewives in Berlin are urged to unite in self-defence.

#### EDIBLE SEAWEED.

*To the Editor of THE LANCET.*

SIR.—With reference to the note in THE LANCET of Feb. 10th under this heading respecting "laver," I think the following quotation from "A Popular History of British Seaweeds," by the Rev. D. Landsborough, A.L.S., in 1851, will prove interesting. He cites Professor W. H. Harvey, M.D., professor of botany, Dublin, in his large work "Phycologia Britannica," as saying of "laver":—

After many hours' boiling, the frond is reduced to a somewhat slimy pulp, of a dark brown colour, which is eaten with pepper and lemon-juice or vinegar, and has an agreeable flavour to those who have conquered the repugnance to taste it, which its great ugliness induces, and many persons are very fond of it. It might become a valuable article of diet, in the absence of other vegetables, to the crews of our whaling vessels sailing in high latitudes, where every marine rock at high-tide abundantly produces it. In its prepared state it may be preserved for an indefinite time in close tin vessels.

The Rev. D. Landsborough adds: "We regard this as a valuable hint," and, in his introduction to his own book, makes the following interesting statement:—

Even in our most common sea-wreck there are substances which may yet be turned to good account. One of these is mannite, the characteristic principle of manna, which my friend Dr. John Stenhouse has detected in many of our coarse seaweeds, but in greatest abundance in *Laminaria saccharina*, which we doubt not took its specific name from this circumstance. A quantity of this seaweed was by Dr. Stenhouse repeatedly digested with hot water, which formed with it a brownish, sweetish, mucilaginous solution. When evaporated to dryness on the water-bath it left a considerable quantity of a saline semi-crystalline mass; this was reduced to powder and treated with boiling alcohol, by which a considerable portion of it was dissolved. The alcoholic solution, on cooling, became nearly solid from the quantity of long transparent prismatic crystals with which it was filled. When purified by a second crystallisation these were deposited in large hard prisms of fine silky lustre. By analysis it was found that this was mannite. The quantity of mannite contained is very considerable: one thousand grains of the seaweed treated in the way described gave about 12 per cent. of mannite. It is very beautiful—as pure white as loaf-sugar, and almost as sweet. Since I wrote the above I have examined and tasted mannite which I got from Dr. Stenhouse about four years ago, and it is as white and sweet as ever. Surely some use may be made of this marine treasure.

I am, Sir, yours faithfully,

EAST ANGLIAN.

Feb. 20th, 1917.

THE Local Government Board last week increased the scales of allowances for the British-born wives of interned aliens. The maximum allowance for wives in London is now 12s. 6d. and outside London 10s., with the addition of 3s. in respect of each child.

P.N.—Standard works of reference give congenital dilatation of the colon as the disease first described by Hirschsprung of Copenhagen in 1880.

Nemo.—Magazines and illustrated papers are still in demand by the British Red Cross for the sick and wounded in hospitals, and should be sent to the Honorary Secretary, Red Cross War Library, Surrey House, Marble Arch, London, W.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

## Medical Diary for the ensuing Week.

### SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.  
MEETINGS OF SECTIONS.

Thursday, March 1st.

OBSTETRICS AND GYNAECOLOGY (Hon. Secretaries—H. Russell Andrews, T. G. Stevens): at 8 P.M.

*Specimens:*

Mr. J. P. Hedley: Uterus containing Carcinoma and Sarcoma.  
Dr. Herbert R. Spencer: Carcino-sarcoma Uteri.  
Dr. Cuthbert Lockyer: (1) Simultaneous Bilateral Tubal Pregnancy; (2) Secondary Neuro-epithelioma in the Ovary of a Child of Three.

*Short Communications:*

Dr. Hubert Roberts: (1) Curious Degeneration of a Cervical Fibroid; (2) Calcified Fibroid which caused Complete Torsion of the Uterus.

*Papers:*

Dr. H. W. Scripture: Two Cases of Psychic Dyspareunia treated by Mental Analysis.  
Dr. Herbert R. Spencer: (1) Four Cases of Undiagnosed Cancer of the Cervix in 200 Total Hysterectomies for Myoma (with six illustrations); (2) Two Cases of Supravaginal Amputation of the Uterus for Sarcoma mistaken for Myoma (two illustrations and four micro-photographs).

Dr. G. F. Blacker: Supravaginal Amputation of Uterus for Sarcoma mistaken for Myoma.

Friday, March 2nd.

LARYNGOLOGY (Hon. Secretaries—Cecil I. Graham, Frank A. Rose): at 4 P.M.

*Cases, &c.:*

Dr. Dundas Grant: (1) Laryngeal Stridor; (2) Nasopharyngeal Growth; (3) Fibromata of Vocal Cords.

Dr. Irwin Moore: (1) Lymphadenoma of Nasopharynx; (2) Bone Impacted in Oesophagus; (3) Pharyngeal Pouches.

Dr. G. W. Dawson: Four Cases.

Mr. Frank Taylor and Captain McKinstry: A Further Note on the Relationship between Vincent's Angina and Peri-dental Gingivitis.

N.B.—Members intending to show cases or specimens are reminded to send in particulars to the Senior Hon. Secretary at least 12 days before each meeting.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY.—4.30 P.M., Paper:—Mr. F. A. Hocking: The War and our Supply of Drugs.

HUNTERIAN SOCIETY, at the Royal Society of Medicine, 1, Wimpole-street, W.

WEDNESDAY.—9 P.M., Demonstration:—Dr. O. Leyton: The Differential Stethoscope.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith-road, W.

FRIDAY.—8.30 P.M., Meeting.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY AND THURSDAY.—5 P.M., Milroy Lectures:—Dr. W. J. Howarth: Meat Inspection, with Special Reference to the Developments of Recent Years. (Lectures II. and III.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY AND WEDNESDAY.—5 P.M., Arris and Gale Lectures:—Dr. W. Harris: The Morphology of the Brachial Plexus in its Relation to Surgery.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

MENTAL AFTER CARE ASSOCIATION.

THURSDAY.—3 P.M., Annual Meeting at 9, Bramham-gardens, South Kensington, S.W.

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY.—4 P.M., Lecture VII.:—Dr. W. G. Savage: The Protection of the Milk Supply. Prof. H. R. Kenwood, Prof. S. Delépine, Dr. C. Porter, and Mr. Wilfred Buckley have promised to take part in the discussion.

### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To the EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C.

## MANAGER'S NOTICES.

## VOLUMES AND CASES.

VOLUMES for the second half of the year 1916 are now ready. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half-year's numbers (inland edition) are also ready. Cloth, gilt lettered, price 2s., by post 2s. 4d. To be obtained on application to the Manager, accompanied by remittance.

## ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8d. The rates of subscription remain as revised in October.

## TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

## TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscription given on page 4.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

## Communications, Letters, &amp;c., have been received from—

- A**.—Ashton-under-Lyne District Infirmary, General Sec. of; Prof. F. W. Andrews, Lond.; Messrs. Allen and Hanbury, Lond.; Association of Registered Medical Women, Lond.; A. G. H.; Messrs. Hunterian Lectures  
ON THE  
INDIAN OPERATION OF COUCHING  
FOR CATARACT.

*Delivered before the Royal College of Surgeons of England  
on Feb. 19th and 21st, 1917,*

BY R. H. ELLIOT, M.D. LOND., F.R.C.S. ENG.,  
LIEUTENANT-COLONEL, INDIAN MEDICAL SERVICE.

PRELIMINARY.

MR. PRESIDENT AND GENTLEMEN.—The operation of couching for cataract is a very ancient one and its origin is lost in the dim mists of history. Celsus performed it and described his method at the commencement of the Christian era, and the silence of the ages has since been broken at intervals of centuries by other European workers and writers. It is, however, possible that this procedure was old in the East before its first mention in the West. In India, and in other Eastern countries as well, the profession of the cataract concher may almost be called a cult, whose art has passed down from father to son through countless generations. It is probable that the operation, as performed to-day in one of the Indian villages, is identical with that which might have been witnessed in the same district when our forefathers were naked savages. Only in a country ruled by tradition could such a state of affairs be possible. The advent of Europeans to India and the interest they took in all that concerned its peoples resulted in a close observation of the steps of the operation. This was to prove the first influence to break the settled monotonous calm it had enjoyed through the ages. As antiseptic surgery developed the progressive Western learnt to look with increasing horror on the crude and filthy methods of the concher, with the result that within the last few decades a vigorous literature on the subject has sprung up. The principal contributors have been Brockman, Exambaran, Hirschberg, Maynard, and Henry Smith. The lecturer has from time to time joined in the discussion, mainly from the clinical side, contributing first an analysis of 125 observed cases of the results of couching and later in 1910 of 550 such cases, in all of which very careful notes had been taken on printed schedules. To these he has since been enabled, by the kindness of Major H. Kirkpatrick, to add another 230, making the total 780. To the statistics thus obtained we shall return later.

THE TECHNIQUE OF THE OPERATION OF COUCHING.

It is important to state at the outset that there are two quite distinct operations performed by the Indian concher. For convenience sake the lecturer would suggest that we should speak of these respectively as "the anterior" and the "posterior," using the terms relatively to the plane of the ciliary body and iris.

*The anterior method*—A needle-like instrument, often a large hard thorn, with a very sharp point, is thrust suddenly through the cornea, and then onwards, either through the pupil or iris, into the periphery of the lens. No sooner is this movement complete than the next begins; using the corneal wound as fulcrum, the operator raises his end of the instrument and thereby depresses its point, which either lies on the surface of the lens or is embedded in its substance. This movement carries the lens backward and downward, and so clears the pupil. Great stress is laid on the immediate restoration of sight, and the operator departs in a blaze of glory, which dies down all too rapidly when sepsis begins to assert itself in the eye.

*The posterior operation* is a much more scientific procedure. Its first step is the making of an incision in the sclera just behind the ciliary body by means of a lancet (Fig. 1), guarded with cotton-wool to prevent its being introduced too far into the globe. Through the puncture thus made a copper probe, provided with a cotton stop, is introduced, and a circular movement is given to the point with the view of breaking through the fibres of the suspensory ligament. As soon as these have been torn through, the lens is depressed by a downward stroke of the point of the instrument, which is then withdrawn.

Such are the bare outlines of the two methods.  
No. 4879.

During the performance of a couching operation the surgeon and his patient squat upon their hams facing each other, in the immemorial fashion of the East, whilst an assistant, in the same attitude behind, holds and steadies the patient's head. (Fig. 2.) The subject is rich with detail, full of living interest, which links such incidents across the centuries with the stories of Bartimaeus and of the Pool of Bethesda, but inasmuch as our topic to-day is pathological we must leave this side of the question to be dealt with at another time and place.

THE RESULTS OF COUCHING.

The testimony of many reliable witnesses has established the fact that the results obtained by the concher deserve to be described as appalling. This will be best illustrated by a few figures from the statistics of the 550 cases to which reference has already been made. In only 10·59 per cent. of these was the vision 1/3 and upward. The figures given refer in each case to the vision corrected with lenses. If every case with a vision of 1/10 and upward be ranked as a success, the concher can claim 21·64 per cent. Again, if anything from 1/10 vision down to a finger count close to the face be counted as a partial success, the figure for this class is 16·69 per cent. This is very much more liberal treatment than would be accorded to any Western surgeon. A very significant point of interest in this connexion is that the majority of the histories are comparatively short. Against these figures we may place the statistics of the Madras Hospital so long ago as 1903, before the present system of rigid antisepsis had been introduced. Recoveries numbered 96 per cent., poor results 2 per cent., and failures 2 per cent. These figures would indicate that the concher was losing 60 per cent. more eyes than we were. If the vast number of eyes submitted to re-clination be taken into account, this 60 per cent. of avoidable loss totals up to a staggering figure. Nor must we forget that even amongst the successes the average vision obtained is greatly in favour of the Western surgeon.

The causes of failure after couching have been worked out from a clinical point of view. The figure for iritis and irido-cyclitis comes to 35·76 per cent. of the total number of cases; glaucoma accounts for 11·05 per cent.; imperfect dislocation of the lens for 8·94 per cent.; whilst minor heads make up for the rest of the failures. There can be no doubt that in a certain number of cases the couchers, owing to mistakes in diagnosis, operate in cases other than cataract: these include glaucoma, optic atrophy, retinitis, and other conditions; but it is only fair to say that, relatively speaking, such errors are very far from common.

The material before us consists of 54 globes, the great majority of which were removed in the Madras Ophthalmic Hospital in the period from 1911 to 1915, though some are of much older date. They were placed in 5 per cent. formalin immediately on removal, and were subsequently frozen and bisected. In a number of instances one half of the eye was submitted to microscopic examination after suitable sectioning. Each of the half globes and a number of microscopic specimens have been photographed and magic lantern slides made therefrom. It will be convenient to classify our observations under a number of separate headings.

THE VARIOUS DIRECTIONS IN WHICH DISLOCATION OF THE LENS IS FOUND TO HAVE TAKEN PLACE.

Before considering this subject in the light of the pathological specimens before us, it is necessary to make certain preliminary statements.

1. Inasmuch as all our material is derived from blinded eyes, it is obvious that we are dealing with the concher's failures alone, and are excluding his successes. In a very large percentage of the latter the lens is seen, during life, to be floating freely in the vitreous, apparently untrammelled by adhesions.

2. The position in which we find the lens on bisection of the eyeball is not necessarily that into which it was thrust at the time of operation, for the changes which occur in the eye as a result of inflammatory action may profoundly alter the position into which the lens was originally forced by the concher. Nor must we forget that in those globes in which the cataract is not tightly tethered by adhesions gravity plays a part.

Having thus cleared the ground, we may start with the statement that, though the lens may be displaced in any direction within the sclero-corneal coat, backward dislocations

are by far the most common, whilst forward ones were only found 4 times in the whole series of 54 globes. None the less, each of these cases possesses considerable interest.

#### *Forward Dislocations.*

(i.) In No. 8 the couching instrument passed through the limbus, and the track of the wound can be plainly followed in microscopic sections. The ciliary body was pushed bodily away from the sclera, and the lens nucleus was forcibly thrust into the space formed by this cyclo-dialysis (Fig. 3); it is to be seen embedded in a dense mass of inflammatory exudate, whilst its capsule, with some of the cortex, lies in the normal situation.

(ii.) In No. 44 the capsule and the nucleus of a Morgagnian cataract are seen floating in the vitreous chamber. During life the nucleus frequently passed backwards and forwards between the aqueous and vitreous cavities. The same phenomenon, though rare, has been observed in other couched eyes.

(iii.) No. 61 is probably an instance of the same kind of thing having happened at an earlier period. (Fig. 4.) Now, however, the small dark Morgagnian nucleus is seen fixed in the lower part of the anterior chamber, into which it doubtless gravitated by its own weight, and there set up inflammatory mischief, which led to its adhesion to the surrounding parts, and to its becoming fixed *in situ* by the formation of organising exudate.

(iv.) In No. 108 the only evidence of lens material present was the capsule of a Morgagnian cataract, which lay impacted in the lower part of the anterior chamber. (Fig. 5.) On section, Morgagnian fluid escaped, and no trace of a nucleus could be detected. It is of interest to record that the writer has, on a number of occasions, operated on Morgagnian cataracts, in which the lens nucleus had been reduced to the thickness of a lamellar disc, or in which no trace of a nucleus could be detected. In this case no adhesions had formed, and during the transit of the specimen to England the capsule fell from its position to the bottom of the bottle.

#### *Backward Dislocations.*

Dislocations backward are the rule, and very wide variations are found both in the completeness and in the direction of the displacement.

Those in which the lenses, or their nuclei, have been completely dislocated into the vitreous, and there lie floating more or less freely (Fig. 6) are 9 in number. In 7 of them the cataracts were Morgagnian, and in the 2 others there was a bulky nucleus with a thin covering of stiff cortex. In 7 the tension of the globe was high; in 6 the retina was completely or nearly completely detached, and in 2 of them it was so much folded as to limit the movements of the lens.

From a consideration of the lenses found floating in the vitreous, we turn to that of those which were entangled in a more or less consistent inflammatory exudate occupying the vitreous chamber. (Fig. 7.) During life such lenses were reported to be fixed or nearly so. In the specimens they are seen to be nested in a mass of exudate, which holds them imprisoned against the ciliary body and the back of the iris. Usually this exudate is limited in quantity, and is confined to the anterior portion of the eye, and principally to the neighbourhood of the dislocated lens. More rarely it is very abundant, and occupies a large part or even the whole of the vitreous chamber. (Fig. 8.) We shall deal with this exudate more fully at a later stage; for the present it suffices to state that it is inflammatory in origin, and that it contains a large number of cells. Of the 6 cases which form this group, 3 were Morgagnian cataracts; 5 were certainly dislocated in their capsule, the sixth is hidden in such dense exudate that it cannot be clearly seen. It is desirable to make it clear that intermediate forms are found between this group and the previous one. In other words, there is no hard-and-fast line between the cases in which the lenses float freely in the vitreous and those in which they are, to a greater or less degree, tethered by the pathological thickening of the hyaloid body.

We have next to consider a group of 10 eyeballs, in each of which the dislocated cataract was firmly fixed to the ciliary body and to the back of the iris by definitely organised fibrous tissue. (Fig. 9.) These globes present certain well-marked features of some interest. 1. The percentage of Morgagnian cataract is much lower than that in the preceding groups, and corresponds closely with the normal frequency of this form of cataract in Indian practice. 2. The cataract was dislocated *in its capsule* in no less than 8 of the 10 cases. 3. The retina was totally detached in 2 and very extensively so in 1; in every one of the remaining

this membrane showed the presence of white dots, apparently on its surface. 4. The time which had elapsed since operation in the cases falling under this group is remarkable. In one it is given as 7 months; in 2 others there is no history; in the remaining 7 the duration was from 2 to 20 years, with an average of well over 7 years. The association of the presence of white dots with these long histories is remarkable and will be taken up in a later section.

No. 99 (Fig. 10) is a specimen of special interest for two reasons—viz. (1) the cataract is fixed to the globe unusually far back, being attached to the retina a little behind the equator of the eye; (2) the dislocation has taken place in an upward direction, and therefore against the action of gravity. From time to time we meet clinically with a couched lens whose suspensory ligament, though torn through over a wide circumference, has been spared at one part, which acts as a hinge. The loosened lens flaps backwards and forwards with the movements of the eye, at times obstructing the pupil and at others being lost to sight. If the hinge is above the cataract usually blocks the pupil when the head is erect; but one meets with cases in which the lens floats up out of the way unless the face is thrown forward into the horizontal plane; this is apparently due to a check-ligament action of the remaining suspensory fibres of the lens. Should inflammation be set up in such an eye and the lens become involved in the exudate it will become fixed, as in this case, in the upper segment of the globe.

When we come to speak of the changes found in the vitreous we shall have occasion to refer to the frequency with which the hyaloid body is represented by a shrunken cone with its apex at the optic nerve and its base in the neighbourhood of the ora serrata. This form, which is well known to pathologists, is due to the anatomical attachments of the vitreous body, and to the fact that the latter undergoes shrinkage after being thickened and opacified by the presence of inflammatory exudate. In studying the present collection one cannot fail to be struck with the fact that the exudate, which fixes, or helps to fix, the lens in its pathologic position, is one with, and part of, this cone-shaped new formation. Before leaving the consideration of this group we must once again point out that no hard-and-fast line separates it from the preceding one, and that intermediate links between the two can easily be pointed to.

In 11 globes, *dislocated cataracts were found matted between the iris and ciliary body in front and the completely detached retina behind*. It is very difficult to say what the nature of the original cataracts was, since all that one can now find is a nucleus, usually rather dark-coloured, embedded in a mass of inflammatory tissue. (Fig. 11.) These nuclei are undergoing steady reduction in bulk as the result of phagocytic action. In 7 of the 11, the lens remnants lie either within the complete capsule, or in its near neighbourhood. The interior of the capsule is usually found to have been invaded by the mass of inflammatory and organising tissue which mats together all the structures (i.e., the iris, the ciliary body, the remains of the lens and the detached retina), and which occludes the angle of the anterior chamber. The completeness of the dislocation varies greatly. In some cases the lens is hardly moved from its usual position, and lies in front of the anterior hyaloid membrane, whilst in others it is displaced into the vitreous cavity. In one instance the detachment of the retina and the inflammatory changes are sharply limited to the lateral half of the eye towards which the cataract was dislocated, but this case belongs more to the next group than to the one we are now discussing.

There are three outstanding and very important features common to these cases: (1) in the great majority of them there is evidence that the operation was followed by severe irido-cyclitis; (2) 9 of the 11 were shrinking eyes with low tension; and (3) the time which had intervened between the couching and the enucleation was between one and two years in every case save one, in which it is probable that the furnished statement of three months was inaccurate. It will be noticed that the histories are much shorter than those in the previous group. This, together with the other two points mentioned, indicates that we have to deal with a condition widely different from that in any of the previous groups. Here the inflammatory process had been induced by a septic infection of the eyes of a decidedly more virulent character, though it fell short of that acme of infectivity,

which leads in so many cases of the Indian operation to pan-opthalmatitis and destruction of the globe within a few weeks.

We come next to a group of 5 cases, which have one feature in common—viz., that the cataract, though dislocated backwards, lies distinctly in front of the anterior hyaloid membrane, and therefore outside the vitreous cavity. (Fig. 12.) In 3 of them the solid parts of the lenses have been pushed back from their original position in such a way that they act like wedges, forcibly keeping the anterior hyaloid membrane in a plane posterior to that which it would normally occupy. Out of these 5 cataracts 4 were cortico-nuclear; the fifth was too much altered for it to be possible to state what its nature was. In certainly 4 out of the 5 moderately severe iridocyclitis had followed the couching, but the exudative process was a much less severe one than that which characterised the specimens of the previous group. The consequence was that there was no such matting of all the parts concerned as is there seen. In every case the detachment of the retina was complete or nearly so, but in not one was the lens enwrapped in its folds. This we may attribute to two causes:—

(1) a merely contributory

one, that the vitreous cavity was not invaded, and (2) that the infection was less virulent and the inflammation consequently less severe than in the members of the previous group.

There is a small group of 3 cases in which the remains of the lens lie *in situ* in the periphery of the capsule, whilst the central portion has disappeared. These resemble the peripheral after-cataracts not infrequently seen following the extraction of a not fully matured lens.

In conclusion, we have to mention two specimens in which the condition found was so unusual that it would scarcely have been possible to have anticipated its occurrence.

The first of these was one of the earliest globes sectioned. A Morgagnian lens, entire in its capsule, was found *thrust behind the retina*. It lay against the scleral coat close to the ciliary body; it had detached the retina over a large area in the neighbourhood of the ora serrata, and had led to a complete separation of it on that (the nasal) half of the eye. The edge of the detached retina had contracted adhesions to the front of the lens capsule and was much puckered in that neighbourhood, doubtless as the result of cicatrisation.

The second specimen (Fig. 13) shows many features in common with the last. The lens is entire in its capsule and is almost certainly Morgagnian; the tear in the retina through which it was thrust now cicatrised up, leaving a puckered scar. The retina is totally detached, and on section the cataract lay as far forward as the separation of that membrane would permit. The pupil was blocked by exudate, and atrophic scars in the iris showed that there had been extensive laceration of that membrane. The globe was removed a year after operation.

The sequence of events in these two cases was probably as follows. The posterior operation must have been adopted and the incision placed far back; a wide tear in the retina resulted; the lens, completely separated from its attachments, was kept entire by the toughness of the Morgagnian capsule, whilst the fluidity of its contents made its insinuation through the retinal tear an easy matter. The fact that a case has recently been recorded in which, in a boy of 17,

the lens spontaneously escaped through a 2 mm. trephine hole, throws a sidelight on such cases as these.

#### ACCIDENTAL INJURIES TO OTHER STRUCTURES THAN THE LENS DURING COUCHING.

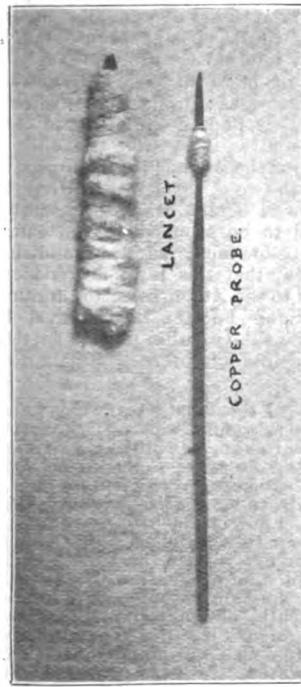

Though the primary object of the Indian cataract coucher is to depress the lens, he may accidentally injure any or all of the other structures of the eye. Evidence of such damage is obtained both clinically and pathologically.

##### *The Cornea.*

Opaque scars on the cornea are quite frequently seen in the out-patient room in eyes which have been subjected to the anterior operation, but are rendered invisible in formalin-mounted specimens owing to the opacification of the membrane. Other evidence of corneal injury is, however, available.

In No. 9 a corneal fistula is present, lying to the inner side of the centre of the eye. (Fig. 14.) The lamellæ immediately surrounding it are largely replaced by connective tissue; the whole thickness of the membrane is markedly reduced, and the lining epithelium is irregular and vacuolated. The iris is very closely adherent to the back of the cornea near the fistula, but more loosely attached further out. There has evidently been some ulceration of the cornea and the formation of a limited staphyoma, which burst at a later date, leaving the fistula now seen. It is probable that the point of fistulisation was determined by the use of a septic instrument at the time of operation, and that septic keratitis followed, leading to early perforation with entanglement of the iris. On the other hand, it is possible that the *enclavement* of the iris occurred as the instrument was withdrawn. In either case, the later sequence of events included the formation of a staphyoma, a secondary rise in tension, and a fresh perforation at the weakest point, resulting in the production of a permanent fistula.

FIG. 2.

Instruments used in couching.

The operation of couching.

In No. 45 the lens capsule is adherent to the back of the cornea, the iris being widely torn and being probably also involved in the synechia. (Fig. 15.) All that remains of the lens is a brown nucleus; the cataract was evidently Morgagnian. It is probable that after the escape of the fluid it contained the lax capsule prolapsed into the wound, either with the gush of fluid which accompanied the withdrawal of the instrument or at a later date.

In No. 116 it is the retina which is impacted in the corneal wound. (Fig. 16.) It seems likely that in this instance the sequence of events was as follows. A severe plastic inflammation resulted from the couching, and involved among other structures a capsular synechia, which had formed at the time of operation or soon after. The vitreous became heavily infected, and the consequent exudate became adherent, on the one hand, to the retina, which thereby underwent total detachment, and on the other to the capsule and its synechia. The progressive contraction of the scar

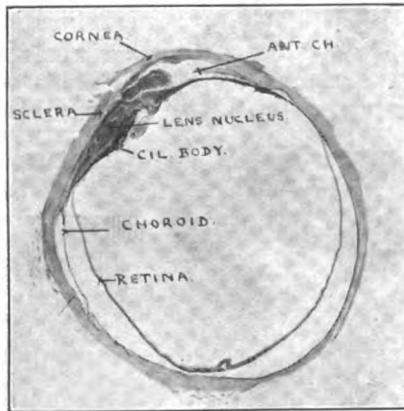

tissue then drew the retina into the wound. This would appear to be the most likely explanation, but it is not impossible, in dealing with such an operation as couching, that the retinal detachment was very extensive, and that the injury inflicted provided a path along which a direct prolapse of the retina may have occurred.

#### The Sclera.

A very large number of Indian cataract-coachers perform the posterior operation, and therefore make their preliminary incision in the sclera outside the limbus. Dr. Ekambaram, who has watched these men at work, believes that they deliberately endeavour to avoid the ciliary body, and it also looks as if some of them purposely place their incision below the external rectus muscle. Like his Western *confrère*, the Indian surgeon does not always succeed in placing his incision just where he wishes to; this is not surprising, as many of them work without any local anaesthetic, and not a few of their patients are nervous and unruly to the last degree. Moreover, it is more than probable that there are different opinions amongst couchers as to the best site for the preliminary cut. These considerations will serve to explain the variety of location of the scars, as found in the specimens before us; indeed, some such explanation is called for, since the cicatrices may be found as far forward as the limbus and as far back as the equator of the globe; what is more, they may be seen in the present collection, not only in their common situation, on or near the horizontal meridian, but in any of the quadrants of the eye.

As a rule, the evidence of injury to the sclera is to be inferred from the interference with the parts beneath that coat, and such instances will be taken up when we come to consider the lesions of the ciliary body and choroid; but occasionally we have been fortunate enough to hit off the scleral scar either in the original division of the globe or during the course of sectioning of part of it for the purpose of microscopic examination.

FIG. 3.

Lens dislocated between c. b. and sclera. (8.)

In No. 306 the track of the original wound can be seen as a pigmented scar in the sclera immediately behind the line of the ciliary processes. Microscopic sections show: (1) that the pigmentation of the deeper part of the scar is due to the impaction of uveal tissue in its depth; (2) that there is a fistulous scar running right through the thickness of the sclera; and (3) that the subconjunctival tissue in the neighbourhood of the wound is permeated by large open spaces lined with endothelium. (Fig. 17.) It is clear that a limited measure of filtration had been established, but this apparently proved insufficient to keep the tension of the eye from rising, as is shown by the deep glaucomatous cupping and by the obliteration of the anterior chamber.

No. 43 shows a scar a little farther back, in the neighbourhood of the ora serrata; but in this case the wound appears to have healed solidly. The pigment of the underlying uveal tissue shows a marked disturbance, whilst before the specimen was cut it was observed that the sclera was pigmented in the neighbourhood of the cicatrix.

In No. 8 the wound lay in the limbus, and the solidifying scar can be traced right through the thickness of the ocular tunic and down to the mass of inflammatory exudate which surrounds the dislocated lens, and fills the angle of the

anterior chamber. Here, again, the uveal pigment can be traced some distance up into the scar, in which it is distinctly entangled.

#### The Uveal Tract.

In quite a large number of couched eyes one can see, during life, evidence of past injury to the iris in the form of more or less extensive scars, many of which probably also involve the ciliary body. Moreover, in other cases, one can infer the presence of injury to the ciliary body and the choroid from the existence of pigmented cicatrices in the sclera. Anatomically, the present series of eyeballs affords additional information on this head. Iris scars are fairly common. In one case, already referred to, the coucher has effected a cyclo-dialysis; in three more the wounds lie across the front parts of the ciliary processes; in six they involved the region of the orbiculus ciliaris, and in one of these the scar lies as much on the choroid as it does on the ciliary body (*vide* Fig. 7); lastly, in four the wounds lie well behind the ciliary body, being placed in two of them just in front of the equator and in two more well behind it. Taking them as a whole, the wounds tend to be grouped in the outer quadrant of the eye, above or below the horizontal meridian. It has already been pointed out that this is in accordance with Ekambaram's evidence as to the site of selection for the incision in the posterior operation. Far the best method of examining these scars is by transillumination with a bright light from behind. Some points of interest remain for consideration.

In No. 44 the wound lay behind the ciliary processes; the instrument, or more probably its point, tore off a tongue-shaped process from the posterior surface of the iris, thus thinning that membrane over this area; the torn portion contracted an adhesion to the subjacent hyaloid membrane, which was itself infiltrated with inflammatory exudate; the appearance presented is curious and interesting.

In several of the globes scar-tissue radiates from the wound area into the surrounding tissues, and is then a strong contributory factor in the production of retinal detachment. In one globe (No. 130) two scars are to be seen, one of which was evidently placed too far back by mistake (Fig. 18); the eye also furnishes contributory evidence that things did not go well during the operation, for the iris is very widely lacerated. It seems probable that the patient was refractory or the surgeon unskilful. In any case it is clear that the instrument was introduced a second time.

In No. 148 a caseating mass in the eyeball (Fig. 19), lying behind the equator, was found to contain a fragment of metal; the latter was most unfortunately lost at the time the section was cut, but it was presumably the tip of the couching instrument, and its presence, taken with the facts that the wound was placed very far back and that dislocation of the lens was not effected by the operation, would seem to indicate that the patient moved violently and that the operator failed in his purpose. The strong, but strictly localised, inflammation excited suggests that the metallic fragment was of copper, and this is in accordance with the known facts of the case, since the probes used by these men to displace the lens are made of that metal.

No. 72 is also a specimen of special interest. Here, too, the puncture lay behind the equator, and there seems to have been some difficulty in penetrating the choroidal and retinal coats which were carried in front of the instrument, the result being a wide separation of these two tunics from their scleral bed. (Fig. 20.)

No. 297, removed six weeks after the operation, is an eyeball which had undergone pan-opthalmatitis and had burst through a point in the sclera on the horizontal meridian somewhere in front of the equator. It is probable that a septic wound of entrance determined the site of the bursting. The lecturer has seen suppurating globes in which the sclera at one point had completely sloughed, the intense inflammation present bearing witness to the violence of the infective process.

#### Uveitis.

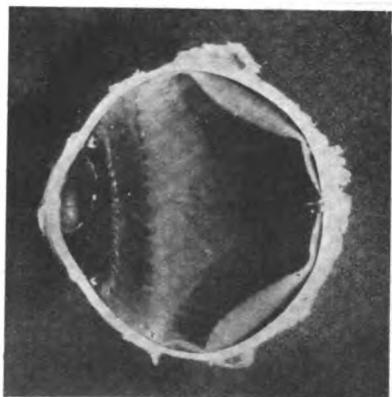

The type of inflammation of the uvea found in these specimens was plastic and was mostly confined to the iris and ciliary body. The intensity of the inflammation varied very greatly. In a number of specimens the evidence of inflammatory action was either absent or only to be detected on very careful examination. On the other hand, a large number of cases present themselves at Indian hospitals in which suppurative pan-opthalmatitis has followed the operation of couching. In Madras such globes were eviscerated, as it was considered dangerous to enucleate them, and much interesting material has thus been lost. All the intermediate stages between the very slight and the very severe

Inflammations can be traced in the specimens before us. This is in accordance with what we should have expected in what was practically a series of inoculations of healthy globes with pathological materials, which varied enormously in their nature and in the quantity introduced. Nor must we forget the great differences in the ages and in the conditions of health of the patients. The plastic mass poured out from the ciliary body and iris had in many cases enveloped the remains of the lenses (Fig. 21), which can be seen in process of disintegration under the action of

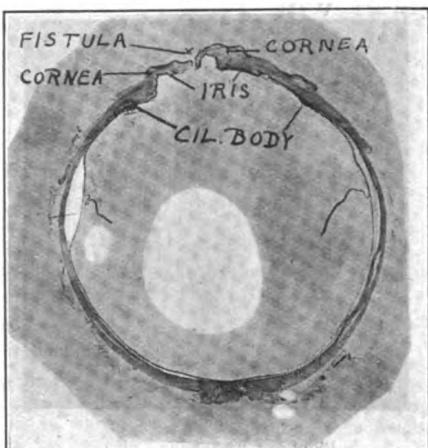

phagocytosis or of fluid absorption. Evidence of calcification of the lens was obtained in at least one specimen, and the same process was also found at work in the uveal coat of several others. The rupture of the lens capsule has provided a ready path of ingress for the inflammatory exudate, which can be seen filling the cavity of the capsule as well as surrounding it; the curly remains, both of the anterior and of the posterior portions of the capsule, can be clearly traced in many of the specimens embedded in dense masses of organising inflammatory exudate. In several such the

absence of the capsule opposite, or to one side of the pupillary area, and the curled-up ends of the elastic membrane, mark the spot where rupture was effected at the time of operation.

In only one instance has any evidence of proliferative uveitis come to light, and in this one the nodule in the iris consists of mononuclear lymphocytes; epithelioid and giant cells are conspicuous by their absence. The interest of this observation centres in the fact that a large number of these globes were removed with the object of guarding against the

occurrence of sympathetic ophthalmia or of making safer the performance of an extraction in the opposite eye. So far as the first indication is concerned it would appear that the danger of sympathetic mischief in the second eye after couching is not great. The deduction thus drawn from pathological data is confirmed by the lecturer's clinical experience, for, as far as his observations go, it is extremely rare to see the second eye lost by sympathetic ophthalmia after this operation.

(To be concluded.)

## THE TREATMENT OF SEPTIC WOUNDS WITH BISMUTH-IODOFORM- PARAFFIN PASTE.

BY LOUISA GARRETT ANDERSON, M.D. LOND.,  
CHIEF SURGEON, MILITARY HOSPITAL, ENDELL-STREET;

AND  
HELEN CHAMBERS, M.D. LOND.,  
PATHOLOGIST, MILITARY HOSPITAL, ENDELL-STREET.

*With an Account of the BACTERIOLOGICAL AND CHEMICAL ACTION OF BISMUTH-IODOFORM-PARAFFIN PASTE, by HELEN CHAMBERS and J. N. GOLDSMITH, M.Sc., Ph.D.*

(Reports to the Medical Research Committee.)

OPINIONS still differ as to the best means of combating bacterial infection of wounds. At the present time two methods commonly used in military hospitals are those of Dr. Carrel and Sir Almroth Wright, and in both of these continuous treatment is required if satisfactory results are to be obtained.

The ideal method is to maintain continuous inhibition of bacterial growth in the wound with the least possible disturbance of the tissues and the patient. In June of last year Professor Rutherford Morison informed us of the excellent results which he was obtaining at the Northumberland War Hospital from the use of a paste composed of bismuth sub-nitrate, iodoform, and liquid paraffin. He kindly gave us the details of his treatment.

The bismuth-iodoform paste has been used extensively in our wards, and we have records of over 400 cases so treated; the results of 62 of these cases are given in Table I. These results are incomparably better than those of the previous year, when we were using eusol, hypertonic saline, with continuous irrigation or frequent dressings.

The composition of the paste is as follows: iodoform 2 ounces, bismuth subnitrate 1 ounce, and liquid paraffin q.s. Any consistency may be made, but the most useful are those of soft butter and thick cream. We have followed the method of treatment recommended by Professor Rutherford Morison in THE LANCET of August 12th, 1916. The patient is put under an anaesthetic, all gangrenous and necrosed tissue is cut away, and the wound thoroughly cleansed; it is swabbed out with rectified spirit, and then a small portion of the paste is vigorously rubbed into the tissues, a little being left in the bottom of the wound, which in many cases is closed with interrupted stitches, and dressed with gauze wrung out in spirit. No further dressing is required for 7 to 14 days. The work in a surgical ward is much reduced when patients do not require daily dressings, and it is a great advantage to the cases if painful and disturbing manipulation can be avoided.

Observation shows that (a) the paste maintains a continuous antiseptic action in the wound; (b) it acts as a lymphagogue, and a free exudation of serum washes the wound from within outwards; (c) it does not prevent the escape of discharge; (d) granulation tissue grows freely in contact with it; (e) drainage-tubes and gauze drains are unnecessary; (f) septic wounds heal nearly as rapidly as non-infected ones; (g) bone union is rapid and the tendency to form sequestra is slight.

Both the constituents of the paste are toxic if absorbed freely. Only one case of such absorption has occurred; it is discussed later. Acting on the recent advice of Professor Morison, the quantity of paste now used rarely exceeds 2 drachms; with this amount the risk of toxic absorption is negligible.

The details of a large number of severe wounds treated with bismuth-iodoform-paraffin paste have been collected and summarised. In order to obtain a true conception of the results the cases have not been selected for their rate of progress; they include all the cases treated by this method wounded during July, August, and September, 1916.

To decide the progress of the cases the data given are: (1) The duration of the febrile period; (2) the length of time before healing; (3) for cases complicated with bone injury,

the persistence of sinuses, and the formation of sequestra. For a comparison of results the first two are open to objection, since many septic wounds are afebrile and the time taken to heal varies enormously, depending largely on the extent of surface injury and the rapidity with which a plastic operation can be done. The third is the most valuable, and the cases complicated with fractured bones have therefore been grouped together. Table I. is a detailed list of 62 cases of compound fractures which had left hospital before Nov. 30th, 1916. Similar tables have been made for the 35 cases of compound fracture still under treatment after this date, and for the wounds not complicated with bone injury.

### Summary of Results.

The total number of compound fractures quoted is 97, the average febrile period was 10 days, and 51·75 per cent. of them were completely healed within 2½ months of being wounded. An analysis of the 62 completed cases in Table I. shows that 50 have healed, only 4 have sinuses, and 8 have superficial wounds.

The 35 incompletely treated cases have an average febrile period of 15·65 days and the average time since wounding was 87·85 days; 14 of these have superficial wounds only. All the cases not complicated with bone injury had healed by Nov. 30th, with the exception of 4. The average febrile period of 40 of the severest of these cases was 3·35 days, and the time in hospital 42 days.

It is an advantage to cases of compound fracture that the wound can be left undisturbed for periods of 7 to 21 days and that drainage-tubes are not required. This is important, as macerated specimens of fractured bones from cases treated with continuous irrigation have shown apertures through the bone directly due to the drainage-tubes and not to the original injury. The best results are obtained when B.I.P.P. treatment is applied soon after the man has been wounded. If partial necrosis of bone has occurred before the case has been admitted the formation of a sequestrum is unavoidable, but it is found that after it has separated one operation is usually enough to effect complete healing.

Six cases complicated with suppurating joints have required amputation after being treated with the paste, and these might be looked upon as failures. In all these cases extensive infection had occurred before they came under this treatment. Post-operative examination of the amputated limb showed that sepsis had subsided in the area to which the paste had been applied, but that the infection had spread extensively, and the paste had not reached the whole of the infected area. For example, in a case of severe gunshot wound of the hand, pus had tracked among the carpal bones and along the tendon sheaths of the forearm.

In a total of 400 only one case of secondary haemorrhage occurred. This patient had a deep wound of the buttock, which was nearly healed. He had been up and moving about for three weeks when an aneurysm of the gluteal artery ruptured, necessitating the ligation of the internal iliac artery.

No case of gas gangrene or tetanus has developed in our wards since B.I.P.P. treatment was begun, although many of the wounds have grown anaerobes and some of them the tetanus bacillus. The data available here are not sufficient to decide whether this result is in any way due to the B.I.P.P., or whether it is entirely due to the antitetanus serum which every patient receives.

One case of iodoform poisoning occurred when the treatment was first begun and when larger quantities of paste were used; it was characterised by fever, emaciation, and delirium. The symptoms subsided when the treatment was discontinued. Several cases of "blue gum" have been observed, but we are not satisfied that these are attributable to bismuth absorption.

In conclusion, the principles which underlie this method of treatment and that of Carrel and Dakin may be compared. In the latter a very powerful antiseptic agent of high solubility is employed, but the effect is so transitory that it is necessary to renew it at short intervals. Professor Morison employs a less powerful antiseptic and one which is of feeble solubility, but which is able to keep up a continuous action in the depths of the wound without requiring to be renewed for days or even weeks.

The improvement in our results with this treatment encourages us to believe that it is along this line that progress will be made in future.

TABLE I.—SIXTY-TWO CASES OF GUNSHOT WOUND COMPLICATED WITH

No.	Index No.	Nature of injury and condition on admission.	Treatment.	Day of disease admitted.	Day of disease B.I.P.P. treatment began.	No. of days febrile since admission.	No. of days after injury when healed or transferred.	Remarks.
1	44	G.S.W. head, large cerebral hernia 2 in. diam., projecting 1 in. Trephined before admission.	No operation. 52 days after admission B.I.P.P. applied to hernia. Before this it had slightly increased.	14	66	0	117	21 days after B.I.P.P. was applied hernia had disappeared.
2	175	Penetrating g.s.w. neck. Fractured cervical vertebra, oesophagus and L. brachial plexus injured. Admitted with suppurating sinus of neck.	28 days after admission operation sinus curetted. 75 days after admission 2nd operation. Loose piece of bone from front of 4th cervical vertebra removed. B.I.P.P. inserted into cavity in front of spine. Wound stitched.	44	119	25	140	Healed.
3	72	G.S.W. R. chest, C.F.R. scapula, 6th and 7th ribs. C.C.F.R. ulna.	8 days after admission operation, F.B. removed from arm. Wounds cleaned, B.I.P.P. inserted.	5	13	5	43	All wounds healed. Later discharged light duty.
4	108	G.S.W. shoulder, C.F.R. scapula, V.S.W.	31 days after admission B.I.P.P. inserted.	3	34	37	79	Auxiliary hospital.
5	178	G.S.W. L. shoulder, C.C.F.R. scapula, L.S.W., F.B.	3 days after admission operation, cleaning, many loose pieces of bone removed, B.I.P.P. inserted.	3	6	2	46	Healed.
6	60	C.F.R. scapula.	2 days after admission B.I.P.P. inserted.	6	8	0	24	Healed. Later discharged full duty.
7	150	C.C.F.R. clavicle and scapula. L.W. open, subclavian vessels exposed.	2 days after admission operation, B.I.P.P. inserted.	6	8	2	92	A.H. Wound not healed. Sequestrum.
8	41	C.F.R. humerus, near elbow, involving joint. Very severe.	1 day after admission operation, wound cleaned, B.I.P.P. inserted.	3	4	1	32	Healed.
9	78	C.F.R. humerus, radius and ulna. Bones of elbow-joint completely blown away.	1 day after admission operation, wound cleaned, sloughs removed, B.I.P.P. inserted.	6	7	17	82	"
10	75	G.S.W. L. shoulder, penetrating wound, S.B.I. surgical neck of humerus.	3 days after admission operation, cleaning, loose pieces of bone removed, B.I.P.P. inserted.	5	8	6	35	Healed. Discharged to duty.
11	142	C.C.F.R. humerus and spine of scapula. Head of humerus removed before admission, V.S.W.	1 day after admission operation, tubes removed, B.I.P.P. inserted.	14	15	21	65	Transferred; almost healed, no sinus. Superficial wound only.
12	147	G.S.W. elbow-joint, C.C.F.R. all bones, V.S.W.	16 days after admission operation, abscess opened, 2 loose pieces of bone removed, B.I.P.P. inserted.	4	20	28	98	Healed.
13	148	C.C.F.R. humerus, lower end. Dislocation of elbow-joint, V.S.W.	5 days after admission B.I.P.P. inserted. 13 days after admission operation, lower end of humerus removed.	23	28	16	123	"
14	3	C.F.R. humerus, lower end.	1 day after admission operation, cleaning, 2 pieces of shrapnel removed, B.I.P.P. inserted.	3	4	18	49	Healed. Later discharged light duty.
15	46	C.F.R. humerus near elbow-joint, V.S.W.	10 days after admission operation, incisions, wound cleaned, B.I.P.P. inserted.	5	15	23	45	Healed. Later discharged full duty.
16	84	C.C.F.R. humerus mid-shaft.	1 day after admission operation, incisions, loose bone removed, B.I.P.P. inserted.	5	6	2	46	Healed. Later discharged light duty.
17	90	C.C.F.R. humerus, surgical neck, T. and T., V.S.W.	On day of admission operation, B.I.P.P. inserted.	12	12	7	66	" " "
18	7	C.F.R. humerus near elbow-joint, V.S.W.	1 day after admission operation, cleaning, B.I.P.P. inserted.	3	4	1	43	" " "
19	97	C.C.F.R. humerus.	3 days after admission operation, cleaning, B.I.P.P. inserted.	6	9	1	49	Healed. Later transferred A.H.
20	106	C.C.F.R. R. humerus mid-shaft. Right hand amputated by shell. C.F.R. L. ulna.	3 days after admission operation, B.I.P.P. inserted.	15	18	5	59	A.H. 97 days all wounds healed. Discharged from Army.
21	177	C.C.F.R. humerus, F.B.	3 days after admission operation, cleaning, many loose pieces of bone removed, B.I.P.P. inserted.	5	8	3	63	Healed. Discharged duty.
22	147	C.C.F.R. elbow. Operation, head of radius removed before admission. V.S.W.	16 days after admission operation, loose bone removed, abscess of joint opened, B.I.P.P. inserted.	4	20	28	98	Healed.
23	16	G.S.W. R. forearm, C.C.F.R. radius, V.S.W. Much loss of tissue.	1 day after admission operation, B.I.P.P. inserted.	8	9	8	65	"
24	18	C.F.R. humerus, clean wounds. C.F.R. radius, V.S.W.	On day of admission B.I.P.P. applied.	8	8	0	55	A.H. Superficial wound, no sinus. Later discharged light duty.
25	51	C.C.F.R. ulna mid-shaft, T. and T.	4 days after admission operation, wounds cleaned. 4 days later B.I.P.P. inserted.	2	10	0	44	Healed. Later discharged duty.
26	92	C.F.R. radius and ulna near elbow.	4 days after admission B.I.P.P. inserted.	14	18	1	66	Healed. Discharged light duty.
27	117	C.F.R. ulna, mid-shaft, V.S.W.	On day of admission operation, B.I.P.P. inserted.	6	6	0	60	A.H. Sinus persistent.
28	142	C.C.F.R. radius, mid-shaft.	7 days after admission operation, B.I.P.P. inserted.	2	9	0	41	Healed. Transferred.
29	169	C.C.F.R. ulna, shrapnel removed, tube inserted before admission.	12 days febrile, then 7 days rising temperature. 19 days after admission operation, B.I.P.P. inserted.	6	25	9	81	A.H. 81 days. Superficial wound, no sinus. Later discharged full duty. Wounds of forearm healed. Temperature due to empyema.
30	55	C.C.F.R. ulna and radius, T. and T., V.S.W., complicated with empyema.	3 days after admission B.I.P.P. inserted.	37	40	22	56	Healed. Later discharged from Army.
31	8	G.S.W. L. hand, C.F.R. metacarpals, V.S.W.	5 days after admission loose bone removed, B.I.P.P. inserted.	3	8	0	33	" " "
32	74	G.S.W. L. hand, C.F.R. metacarpals, two fingers blown off, V.S.W.	4 days after admission B.I.P.P. inserted.	5	9	9	68	" " "
33	109	G.S.W. L. hand, C.C.F.R. 5th metacarpal.	5 days after admission operation, B.I.P.P. inserted.	9	14	3	30	A.H. Later discharged full duty.
34	76	C.F.R. ilium, L.S.W., F.B. near sacro-iliac joint.	8 days after admission operation, B.I.P.P. inserted.	6	14	7	45	A.H. 63 days after wound discharged full duty.
35	31	G.S.W. buttock, S.B.I. sacrum, F.B.	13 days after admission operation, wounds cleaned, B.I.P.P. inserted.	4	17	19	92	Healed. Later discharged from Army.
36	139	C.F.R. femur, S.B.I., shaft intact.	4 days after admission operation, cleaning, B.I.P.P. inserted.	8	12	7	50	A.H. No sinus.
37	33	C.C.F.R. femur.	3 days after admission operation, cleaning, B.I.P.P. inserted.	6	9	7	38	Healed. Later discharged light duty.

## FRACTURED BONES, WHICH HAD LEFT HOSPITAL BEFORE NOV. 30TH, 1916.

No.	Index No.	Nature of injury and condition on admission.	Treatment.	Day of disease admitted.	Day of disease B.I.P.P. treatment began.	No. of days febrile since admission.	No. of days after injury when healed or transferred.	Remarks.
38	34	c.fr. femur, v.s.w.	4 days after admission operation, B.I.P.P. inserted.	5	9	3	84	Healed. Later discharged light duty.

## THE BACTERIOLOGICAL AND CHEMICAL ACTION OF BISMUTH-IODOFORM-PARAFFIN PASTE.

BY HELEN CHAMBERS AND J. N. GOLDSMITH, M.Sc., PH.D.

The clinical results obtained by the use of bismuth-iodoform-paraffin paste recorded in the previous paper have been so striking that an explanation of its action is desirable, particularly as Professor Rutherford Morison, in his paper in THE LANCET of August 12th, 1916, p. 269, states that the explanation of its action is unknown. A series of bacteriological and chemical tests were therefore carried out as far as possible in parallel.

The bacteriological tests have been made in tubes of nutrient broth containing 20 per cent. horse serum, the test organism being a 24-hour culture of *Staphylococcus pyogenes aureus*. The practical details are noted in Table II.

A preliminary test showed that B.I.P.P. completely sterilised after 24 hours' incubation, whereas pastes of bismuth subnitrate or of iodoform with small quantities of paraffin have no appreciable action.

Bismuth subnitrate in water produces a marked acid reaction due to liberation of free nitric acid. In saline or in nutrient broth containing 20 per cent. serum there is a double decomposition with sodium chloride, bismuth subchloride and sodium nitrate being formed; no marked alteration in reaction occurs. The addition of 10 per cent. bismuth subnitrate to the test medium causes partial sterilisation which in time becomes complete; very little effect is obtained with smaller quantities. The admixture of paraffin to the bismuth subnitrate masks its action even when the bismuth salt is present in quantities of 10 per cent.

Medium : 7 c.c. nutrient broth (reaction + 5); 2 c.c. horse serum; 1 c.c. emulsion of *Staphylococcus pyogenes aureus* in saline. Circa 1 × 10<sup>9</sup> organisms. Drug added and tubes incubated for 24 hours at 37° C. 1 c.c. diluted 1/1000, plated on agar.

17.	Iodoform, 1 gm. + bismuth subnitrate 0·5 gm., CO <sub>2</sub> atmosphere after twice washing with medium to remove free iodine. 1, 2, and 3 days' incubation. After 3 days air admitted and 10 c.c. fresh medium added. 24 hours incubation	∞
18.	B.I.P.P. removed from a wound after 2 weeks	10

— = sterile. ∞ = very numerous colonies.

Chemical experiments on similar lines showed that 1 gm. of bismuth subnitrate, incubated at 37° C. with 10 c.c. of normal saline for 24 hours, produced an acid reaction, N/750, with no bismuth in solution; prolonged incubation

(5 days) removed all the chloride, and produced an acid reaction with bismuth in solution. The bactericidal action of the bismuth subnitrate can therefore be attributed to surface precipitation of the protein and metallic poisoning, the acid reaction developed in saline in 24 hours being insufficient to produce the result.

Iodoform is practically insoluble in water or saline, but is slightly soluble in paraffin, 2.15 gm. dissolving in 100 c.c. at 37° C. When in solution, and in the presence of oxygen, it is readily decomposed by light or heat, liberating free iodine, the equation, according to Schoorl and Van den Berg,<sup>1</sup> being:

The decomposition started by light continues in the dark. Iodoform dissolved in liquid paraffin is not nearly so rapidly decomposed by light as its chloroform, benzene, and carbon bisulphide solutions, and light does not therefore play an important part in the present experiments, particularly as the reaction in the dark is very slow at ordinary temperatures. At 37° C., and in darkness, access of air is the ruling factor.

Two samples of iodoform from the hospital dispensary exhibited great differences in their rate of decomposition. One sample contained in 1 gm. free iodine equivalent to 0.3 c.c. N/100 iodine and decomposed more rapidly than the other, which originally contained no free iodine. The iodine formed by the decomposition of solid iodoform appears to be in solid solution in the iodoform and is only partly available for disinfectant purposes.

As is well known, iodoform in large amounts has a slight bactericidal action, probably due to liberation of iodine; in smaller quantities it has no appreciable effect *in vitro*. When iodoform is suspended in paraffin the disinfectant action depends on the free access of air and, incidentally, on the amount of paraffin added. When used in a thick paste mixed with small quantities of paraffin the drug remains at the bottom of the tubes and the antiseptic action is slight. With larger quantities the paraffin solution of iodoform floats, liberation of iodine occurs, and the medium is sterilised.

In view of the liberation of iodine from B.I.P.P. it became important to find the concentration of iodine in liquid paraffin which would sterilise. 3 c.c. of iodine solution in paraffin of N/100 concentration (1 c.c. = 0.00127 gm.) sterilised 10 c.c. of culture = 1:2600 containing 15 per cent. serum. Dakin, Cohen, Daufresne, and Kenyon,<sup>2</sup> who employed 50 per cent. serum and therefore more protein in solution, found that iodine sterilised in 1:1000 but not in 1:2500. The volume of air at 37° theoretically sufficient for the liberation of 0.00381 gm. iodine by oxidation of iodoform is 1.03 c.c.

With the object of ascertaining whether the action of the B.I.P. paste is dependent on the base or on the acid of bismuth subnitrate, experiments have been made replacing 1 gm. of bismuth subnitrate with the equivalent weight of one of the following: Bismuth oxide, bismuth subchloride, bismuth carbonate, bismuth subiodide, and sodium nitrate. None of these drugs had any bactericidal action, either alone or mixed with iodoform, with or without paraffin. These bismuth compounds do not yield oxidising agents when treated with normal saline, nor does sodium nitrate readily act as an oxidising agent. Bismuth subiodide which is contained in traces in old specimens of B.I.P.P. stored in glass bottles is also inactive. It follows that the action of the paste is not due to bismuth nor to the presence of a nitrate as distinct from free nitric acid yielded by bismuth subnitrate.

A study of the chemical changes which occur when B.I.P.P. is incubated with normal saline (the details of some of these experiments are given in Table III.) shows that the most important changes are the following:

1. The oxidation of iodoform, the liberated iodine dissolving in liquid paraffin. The supply of oxygen is the ruling factor. If protein or other iodine absorbents are present the iodine diffuses out readily from the paraffin layer; the yield of free iodine is less in the absence of these substances. 2 gm. B.I.P.P. yielded 2.4 c.c. N/100 iodine in 48 hours' incubation at 37° with broth and serum.

TABLE III.  
In the following experiments (Nos. 1-8) 2 gm. of B.I.P.P. were heated to 37° C. under the conditions stated.

No.	Air available.	c.c. saline.	Time in hours.	Iodine in saline.	Free iodine in residue.	NaCl original grammes.	NaCl final grammes.	Reaction.	Bismuth in solution.

I As c.c. N/100 iodine.

R = reneutralised.

\* In No. 7 the B.I.P.P. used had been previously heated at 37° C. for 24 hours in an open tube; in No. 8 the B.I.P.P. had been previously heated at 100° for 6 minutes. Free iodine was estimated before and after incubation, but the table shows only the iodine liberated during incubation.

† In No. 9 the B.I.P.P. was replaced by 1 gm. BINO<sub>3</sub> + 2 gm. CHI<sub>3</sub> + 3 c.c. paraffin, in No. 10 by 2 gm. CHI<sub>3</sub> + 3 c.c. paraffin; in both experiments the saline was replaced by distilled water and the temperature was 47° C.

2. An exchange of acid radicles between the sodium chloride and the bismuth subnitrate, so that the latter may be converted as to 60 or 70 per cent. into bismuth subchloride. This change occurs both *in vitro* and also in B.I.P.P. in a wound, as shown by the following analysis:

	% Bi <sub>2</sub> O <sub>3</sub>	% HNO <sub>3</sub>	% Cl.
Original BINO <sub>3</sub>	80.91	7.7	—
BINO <sub>3</sub> recovered from B.I.P.P. in a wound 3 weeks	72.1	2.69	8.4

3. The formation of traces of iodine in the saline solution. The following negative results are also of interest:

1. The absence of bismuth salts in the solution except in exceedingly minute quantities; on one or two occasions this amounted to 0.0002 gm., as BINO<sub>3</sub> in 10 c.c., but in the majority of experiments with normal saline it could not be detected.

2. The absence of more than traces of bismuth subiodide in the B.I.P.P. after incubation.

If B.I.P.P. is heated on a water bath until it is distinctly coloured by free iodine the subsequent rate of decomposition at 37° is considerably increased.

It seems clear, therefore, that the bactericidal action of B.I.P.P. results from the free iodine liberated from the oxidation of iodoform by oxygen and by the nitric acid formed by the hydrolysis of bismuth subnitrate. One gramme of this drug incubated at 37° C. for 24 hours with 10 c.c. of water produced N/50 nitric acid (0.1 per cent. HNO<sub>3</sub>). In experiments made with iodoform and N/50 or N/100 nitric acid added as oxidising agents, in the absence of bismuth subnitrate, sterilisation was obtained, and the corresponding chemical tests suggested that when the oxidation has begun nitrous acid (of which a trace was detected) can act catalytically with atmospheric oxygen as it does on potassium iodide.

On this hypothesis it should be possible to reduce very largely the quantity of bismuth subnitrate and still obtain bactericidal action, provided oxygen is available, but in the absence of oxygen the reaction should cease, even with the usual maximum amount of bismuth subnitrate. Both these conclusions were confirmed by *in vitro* experiments. The chemical analyses gave the following results:

Oxidation of iodoform in presence of bismuth subnitrate and saline.—2 gm. of iodoform, 10 c.c. of normal saline, and varying quantities of bismuth subnitrate were heated for 5 days at 37°.

—	Bismuth sub-nitrate.	Acid reaction.	Free iodine in residue.	Total iodine in solution.
1	0.1	N/10,000	2.3 c.c. N/100	0.2 N/100
2	0.5	N/2,000	2.2 " "	0.2 "
3	1.0	N/30	6.1 " "	0.1 "

In the third experiment the sodium chloride originally present was 0.078 gm. which was found to be partly converted

<sup>1</sup> Chem. Centralblatt, 1905 (2), 1718. (Extensive literature—e.g., Hardy and Willcock, Proc. Royal Soc., 1903, lxxii, 200; Plotnikow, Zeit. f. physikal. Chemie, 1911.)

<sup>2</sup> Proc. Royal Soc., 1916, lxxxix, 251.

into sodium nitrate, the final quantity of sodium chloride in solution being only 0.049 gm.

In the bacteriological tests the bismuth subnitrate has been reduced from 1 gm. to 0.001 gm., with no marked diminution in the antiseptic action. Further, when oxygen is eliminated by replacing the air with an atmosphere of CO<sub>2</sub> (any free iodine originally present in the mixture having been removed by washing with fresh medium), the paste has no appreciable antiseptic action. Air subsequently admitted enables it to disinfect as usual.

The mechanical effect of fluids percolating through a film of B.I.P.P. tends to remove the paraffin—there is then a possibility of bismuth disinfection; some of the bismuth subnitrate, which is lighter than iodoform, is also removed. The chief reaction is the continued liberation of small quantities of iodine from a mixture practically insoluble in saline, governed by the oxygen supplied from the air or from arterial blood.

Numerous cultures taken from open wounds under B.I.P.P. treatment have shown, without exception, that the wounds are not bacteriologically sterile, but there is a reduction in the number of bacteria. No change in the flora has been detected. A large number of the wounds are infected with anaerobic organisms, and *B. perfringens*, *B. malignantæma*, *B. Hibler IX.*, and *B. tetani* have been recovered from some of these cases. Although the organisms are present in the wounds they are not able to proliferate freely, and the wounds heal as if surgically clean.

Most of the cases under this treatment excrete to a varying extent products of the decomposition of iodoform, and the general effects of iodide absorption may have some bearing on the results.

## CLINICO-ANATOMICAL INVESTIGATION OF A RAPIDLY FATAL CASE OF GENERAL PARALYSIS DUE TO ACQUIRED SYPHILIS.

BY T. E. KNOWLES STANSFIELD, M.B., C.M. EDIN.,  
MEDICAL SUPERINTENDENT, LONDON COUNTY ASYLUM, BEKLEY;  
HON. FELL., SOC. CLINIQUE DE MÉDECINE MENTALE, PARIS;  
HON. CONSULTANT FOR MENTAL DISEASES TO THE  
EASTERN COMMAND;

AND

F. W. MOTT, M.D. LOND., F.R.S.,  
PATHOLOGIST TO THE LONDON COUNTY COUNCIL ASYLUMS.

THE following case has several striking and unusual features which we think should be recorded. It is that of a young married woman, 26 years of age, who came under care at Bexley Asylum on June 19th, 1916, suffering from general paralysis. Her previous history is as follows:—

She was the tenth child of a family of 11, seven of whom survive her, all said to be healthy and strong. The father died at the age of 59, following an accident sustained two years previously. The mother is alive and well and was the source of our information. The patient was a tall girl for her age, well developed, and had no indications of any congenital disease. She had commenced work as a daily girl at 15 years of age, and was afterwards engaged at a mineral-water manufactory until her marriage at the age of 19. She was "considered a bright, intelligent girl," was "always fond of her home," "never gave her parents any trouble," and was "never given to racing out at night." She kept company with the young man she ultimately married from the age of 17, was married at 19, and gave birth to her first child a week later. The infant was "a fine, big, healthy child," and was suckled by the mother until it was ten months old. The boy is now living, and is a well-developed intelligent boy just seven years of age. His blood was examined by Dr. Mott and was found to give a negative Wassermann.

Two years after her marriage the patient gave birth to a four months' foetus. She had a very bad time and took several weeks to recover. Fifteen months later she gave birth to a dead child which was thought to be seven and a half months. During this pregnancy she complained bitterly about pains in her head; she had bad sore-throats very frequently, and her voice became much altered in tone. She became pregnant a fourth time, and expected her confinement at the end of March, 1916. Her mother stated that the patient was out shopping on Saturday evening (March 4th)

with her little son. She called at her house, and when she sat down commenced trying to speak, but her words all ran into each other and her voice became very tremulous, so that what she said was unintelligible. She took her home and the patient partially recovered her speech in about half an hour, though it still remained very tremulous and indistinct. She was not seen by a doctor. She became markedly worse the following Thursday; she had three fits, and was taken to the infirmary. Information obtained from the infirmary was to the effect that she was in a semi-conscious condition; vomiting continuously; incontinent; did not speak unless addressed, and then only with difficulty; and did not sleep well. She was confined of a female child, weighing 5½ lb. and measuring 19½ inches, four days after her admission. No albumin was found in the urine. On March 17th she became melancholic; was still incontinent, but was taking food. She remained in more or less the same condition until June, when she became noisy and inclined to wander. There was nothing remarkable in connexion with the labour, and the child died of infantile atrophy.

For this information we are obliged to the medical officer of the infirmary, and he also stated that there was no good evidence of congenital syphilis.

She was certified insane on June 16th, the medical certificate being as follows:—

That she is restless; does not seem to know people; says she loves me; appears to have hallucinations of sight and hearing; talks to imaginary people; does not appear to have any memory; is dirty in habits. Nurse states that she is noisy and troublesome; that she talks to imaginary people; says her baby is in the next bed to hers, and swears at it; says another patient has stolen her baby; is spiteful to those who come near her; does nothing for herself.

She was admitted to Bexley on June 19th, her physical and mental state then being as follows:—

General bodily condition and nourishment fair. No stigmata of congenital disease. Complexion fresh. Palate: wide arch. Teeth well formed and regular. An abundance of brown, fine hair. Nervous system: motor impairment considerable, partly in consequence of incoordination. Coarse general tremors. Speech tremulous. Coordination of arms impaired; of legs very bad. Station and gait impossible. Tactile sensation could not be tested. Knee-jerks absent. Ankle clonus spurious. Deep reflexes of arms brisk. Brisk flexor plantar reflex. Other superficial reflexes indefinite owing to muscular contractions. Deglutition normal. Sight good. Movement of eyes complete. Pupils: size medium, equal, regular. Mobility to light: right nil; left very slight; to accommodation (r. and l.) fair; consensual (r. and l.) nil. Exophthalmos: nil. Other systems: nothing remarkable.

Mental state on admission. She was confused, quite unable to realise the nature of her surroundings, and could not give any reliable information about herself. All the mental faculties were grossly impaired. Though she chattered a great deal of nonsense about herself, there was no evidence of definite hallucinations or delusions. Most of the time she was unduly elated, hilarious, and self-satisfied, but she readily became lacrymose. She was restless, garrulous, picked at her bedding, and had a trick of stuffing the corner of the sheet into her mouth. She showed a good deal of purposeless resistiveness and muscular rigidity. Was defective in habits and required spoon-feeding.

Her condition was diagnosed as one of general paralysis of the insane; but as we had no definite history with her it became a question, in view of her age and the vague statement accompanying her that she had a family, as to whether she was a case of congenital or acquired syphilis. Her blood and cerebro-spinal fluid were examined at the Pathological Laboratory of the L.C.C. Asylums, Maudsley Hospital, and found to give a very strongly positive Wassermann reaction. On June 26th her condition was noted as follows:—

She is suffering from general paralysis of the insane. She is very demented, happy, contented, and emotional. Her memory is grossly impaired, and she is unable to converse on the simplest topic. In happy, slow, slurred, and hesitating speech, she said: "I love gentlemen." She is fairly nourished.

The disease made very unusually rapid progress, and she died from exhaustion of general paralysis on Sept. 25th. Only a partial autopsy was possible, but we managed to

obtain the brain. Macroscopic examination did not reveal any of the naked-eye appearances of brain syphilis or of G.P.I. The granulation of the floor of the fourth ventricle is the most characteristic and constant naked-eye sign, and it was absent in this case; moreover, the membranes were not thickened. Nevertheless, an emulsion of a small portion of the frontal lobe examined by Dr. Mott microscopically by dark-ground illumination and by Fontana staining method demonstrated the presence of numbers of spirochaetes.

We had several interviews with the husband, who stated that he remembered his wife complaining of her hair coming out and of being troubled with sore-throats and headaches, more especially during the period which followed her third pregnancy. We obtained a sample of his blood for examination, as well as that of the boy, the results of which have been mentioned. The husband denied having suffered from any form of disease, and certainly bore no obvious traces. He was emphatic in his protestations against ever having suffered from a sore either of the genitals or elsewhere. Dr. Mott found that his blood gave a positive (+40) Wassermann reaction.

The points which occur to us as being worthy of especial notice are:—

1. The extreme rapidity which characterised the progress of the disease, six months and a few days only elapsing between the earliest observed symptoms and death.

2. The naked-eye signs of the disease were not apparent, and, but for the presence of the Wassermann reaction of the cerebro-spinal fluid (during life and post mortem) and the finding of the spirochaetes in the brain, it would have been difficult to have come to a decision as to the cause of the mental symptoms manifested during life.

3. The case is of interest in showing the value of the examination of the cerebro-spinal fluid as a means of diagnosis in even the earliest stages of the disease; it is also of interest in the fact that the spirochaetes were found in an emulsion of the apparently normal brain by the dark-ground illumination method, after five minutes' search. This conforms with the experience of Levaditi, who showed that spirochaetes could be found at the seat of inoculation before the chancre appeared. There was no time for the connective-tissue formation to occur in a sufficient degree to cause naked-eye changes of the brain, but histological investigation of sections of the frontal and central cortex, however, showed the characteristic chronic perivascular inflammation; and by the special silver method spirochaetes were found in sections of the inflamed areas. It may be inferred, therefore, that the multiplication of the syphilitic organisms in the brain was the cause of the deviation of the complement by the cerebro-spinal fluid, and that the abundant toxins produced by the rapid growth of the organism were responsible for the perivascular inflammation and neurone degeneration.

4. These histological microscopic changes may be correlated with the characteristic clinical symptoms presented by the case for the comparatively short time prior to the fatal issue. It has been the experience of Dr. Mott to find that the spirochaetes are more easily found in these rapidly fatal acute cases, in which macroscopic changes are not evident, or not markedly so. A likely spot for finding the spirochaetes may be disclosed by feeling gently the cortex, and if the resistance is less marked an emulsion of that region is advisable, but emulsions of cortex from several soft spots should be made. It may be mentioned here that in 100 successive cases of general paralysis spirochaetes were found in 66. In advanced cases where there has been arrest of active symptoms, and death has occurred from some intercurrent disease in the demential stage, the syphilitic organisms are less easily found.

5. Contrary to the original statement of Noguchi, the spirochaetes are found in the inflammatory cell infiltration of lymphocytes and plasma cells of the perivascular sheaths, rather than in the cortical brain substance; and this has been my experience in other cases. This being the case, we can understand why the cerebro-spinal fluid gives a positive reaction in the earliest stages of the disease, for the perivascular sheaths form a part of the irrigation system of the cerebro-spinal fluid, which functions in all probability as the lymph of the brain. It is the toxins produced by the spirochaetes, and not the organisms themselves, which produce the chronic inflammatory process, for only at certain places can the spirochaetes or their

degenerated forms be seen. Consequently the spirochaetes at a focus of development, by virtue of the soluble toxins produced, may have a far-reaching irritative effect on the perivascular lymphatic sheaths, leading to widespread congestive stasis and neurone decay. Prior to the decay the toxins contained in the perineuronal spaces may irritate and lead to increased functional activity of the neurones, and the excitement evinced in the early stages of this disease may be thus accounted for by intoxication effects acting more or less on the whole brain, but, as in the case of generalised epileptiform seizures, on the motor cortex especially.

Although there was no naked-eye cortical atrophy, indicative of neuronic decay and destruction and neuroglia-cell proliferation, yet the histological examination showed that both these morbid processes were present over a wide area of the fronto-central cortex.

## THE PREVALENCE OF *SPIROCHAETA EURYGYRATA* IN EUROPEANS AND NATIVES IN THE GOLD COAST.

By J. W. SCOTT MACFIE, D.Sc., M.B. EDIN., PATHOLOGIST, GOLD COAST.

RECENTLY, owing to the return to England of a large number of soldiers suffering from dysentery and diarrhoea, a general interest has been evoked in a number of protozoal organisms which for many years have been familiar to every worker in the tropics. Amongst others the spirochaetes found in the intestines have come in for their share of attention, and the commonest species, *Spirocheta eurygyrata*, has recently been described in detail by Fantham (1916).

In West Africa the occurrence of small spirochaetes in the faeces has long been recognised, but the consensus of opinion has been that they were not pathogenic. Under abnormal conditions, in cases of dysentery or diarrhoea, however, they were known sometimes to occur in myriads, and it was believed they might in these circumstances be a subsidiary cause of illness. In view of the revived interest in these organisms a brief note on their prevalence in Europeans and natives in the Gold Coast Colony may not be inappropriate.

### Materials Examined.

Previous experience had proved that the spirochaetes were most readily found in the faeces after purgation, and for this reason most of the specimens examined were taken from patients to whom a saline aperient had been administered for simple constipation, as a preliminary to surgical treatment, or for the purpose of ascertaining if helminth infections were present; but in addition the fluid or semi-solid motions from cases of dysentery and diarrhoea were searched as well as some normal stools. The specimens were examined both fresh and after fixation and staining. Leishman's stain and gentian violet were used; the latter when drawings were to be made for the purpose of measuring the length of the organisms, and the former when the structure of the cytoplasm was to be studied.

Flagellates, *Trichomonas*, &c., are also very commonly met with in faeces in the Gold Coast and had to be remembered, as their flagella, which they are apt to lose, sometimes simulate spirochaetes. This fallacy, although it had to be kept in mind, was not found to be a serious difficulty in practice. The (?) sprouting vegetable cells, so troublesome in many animals, are, fortunately, absent from men.

In this manner a large number of Europeans and natives and a few Syrians have been examined since February, 1916, and in every case spirochaetes have been present. I have not failed so far to discover them in a single individual examined for these organisms at Accra. In the Europeans they were generally relatively scarce, but in many of the natives and some Europeans they were abundant. Cases of amoebic dysentery were not, as a rule, exceptionally heavily infected, but in some patients suffering from diarrhoea they were so numerous that it was difficult to believe that they could have been entirely harmless.

The last 20 cases examined, which included 5 Europeans, 14 natives, and 1 Syrian, may be taken as a typical sample. In the Europeans the spirochaetes were scanty in 4 and abundant in 1, the latter individual being a healthy man.

One subject was simultaneously infected with *Entamoeba histolytica* and another with *Trichomonas intestinalis*. Both loosely and closely coiled organisms were found in 2 cases, and in the other 3 loosely coiled specimens only. In the natives the spirochaetes were abundant in 8 and scanty in 6 persons; in 4 they were countless. Three of the subjects were simultaneously infected with *E. histolytica*, 3 with *Trichomonas intestinalis*, and at least 2 with *Blastocystis enterocola*. Of the 4 most heavily infected individuals 2 showed spirochaetes only; 1 harboured *Trichomonas* and *Blastocystis*, and 1 *E. histolytica* and *Blastocystis* as well. Only loosely coiled spirochaetes were found in 10 cases, only closely coiled ones in 1, and in the remaining 3 both types were present. The single Syrian examined harboured a few loosely coiled spirochaetes; his faeces also contained ova of *Tenia saginata*.

#### Morphology.

Werner (1909) described two types of spirochaetes found in his own faeces at a time when he was apparently in good health, but as he had previously been in German South-West Africa his infection may have been contracted in that country. The one type, to which he gave the name *S. eurygyrata*, showed widely separated coils and varied in length from  $4\cdot6\ \mu$  to  $7\cdot3\ \mu$ ; the other, *S. stenogyrata*, had a closely coiled body from  $3\cdot5\ \mu$  to  $6\cdot1\ \mu$  long.

Fantham (1916), as a result of his study of the spirochaetes, found in the motions of soldiers from Gallipoli and Flanders, has concluded that the two species described by Werner are really morphological variations of the same organism, which he finds may show widely or closely set waves according to the nature of its movements, and may measure from  $3\ \mu$  to  $15\ \mu$  in length. The spirochaete has pointed ends and is about  $0\cdot25\ \mu$  broad.

The spirochaetes found on the Gold Coast conformed fairly well to the description given by Fantham. In the majority of the specimens the organisms showed only a few widely set waves, but in a few they were all closely coiled, and in others both forms were met with. Both types of the spirochaete had pointed ends, and when measured were found to be of about the same length and breadth. It was decided, therefore, that although superficially unlike each other they must really be forms of the same parasite, a conclusion which was confirmed by measuring a large number of

them the coiling of the body was more or less obscured. Progression was accompanied by rapid helicoid movements, the axis of the spirochaete being often a straight line. Either end might advance, and a reversal of direction was frequent. Catherine-wheel-like movements were seen and in stained preparations tangles were found. The body was

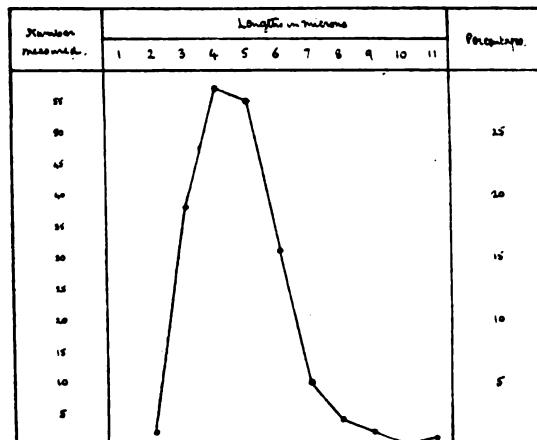

Chart showing measurements of length plotted as a curve.

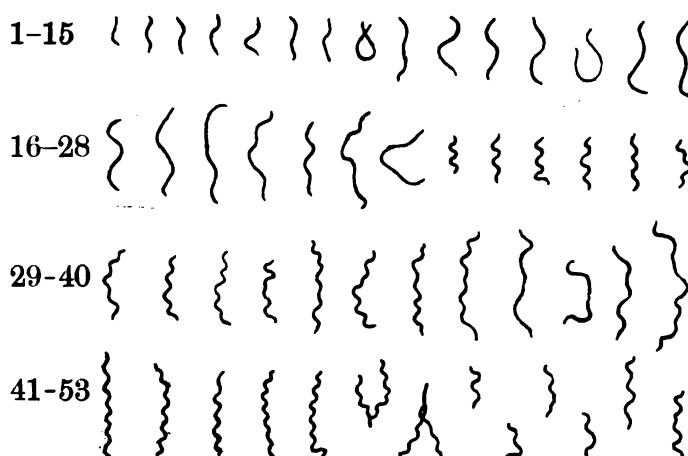

flexible and was bent into a variable number of waves or coils. Some spirochaetes were simply curved like a bow, many had two or three waves, and some had as many as six or more. The number of the waves varied with the thickness of the organism and also with the character of its movements. I cannot, however, completely confirm Fantham's statement that the number of coils is primarily an index of rate of motion, for on the one hand the most active spirochaetes were those showing lashing movements, and they were only loosely coiled, and on the other hand quiescent or dead specimens were often closely coiled. The most closely coiled organisms I ever saw were some that had died in a preparation with hydrochloric acid (0.2 per cent.) which had been incubated at  $37^\circ\text{C}$ . for six hours (Figs. 41-45). The spirochaetes in the saline solution control to this experiment were still alive and active and were decidedly more loosely coiled (Figs. 48-53). The ends of the organisms were pointed. The cytoplasm was generally homogeneous, but occasionally the body was seen to be banded by chromatin rodlets. So small and delicate were the spirochaetes that the membrane, if it existed, was in most specimens indistinguishable; in a few, however, there did appear to be some indication of its presence. Coccoid bodies were seen within a few specimens.

The spirochaetes were very slender, measuring about  $0\cdot25\ \mu$  in breadth. It was impossible to determine their diameter with accuracy, but some specimens were sensibly thicker than others.

The length of the spirochaete was determined by measuring 200 individuals taken as they came from 10 different cases (see Table I.). The shortest measured  $2\ \mu$ , the longest  $11\ \mu$ , and the average was  $4\cdot7\ \mu$ . This statement is, however, misleading, as the longer forms were rare, and the same remark applies, I believe, to that made by Fantham to the effect that *S. eurygyrata* varied in length from  $3\ \mu$  to  $15\ \mu$ . A much better idea of the length of the spirochaete is obtained by plotting the measurements as a curve, as has been done in the chart shown above. It is then seen that 75 per cent. of them measured from  $3\ \mu$  to  $5\ \mu$ , and no less than 90 per cent. were

within 4 microns of each other in length, between  $3\ \mu$  and  $6\ \mu$ . Very occasionally extremely long individuals were found, some of which exceeded  $30\ \mu$  in length. These forms I believe to have been multiple.

The spirochaete underwent both longitudinal and transverse division. Dividing forms composed of two daughter spirochaetes united by a delicate filament were relatively rarely seen, but those that were found measured from  $7\ \mu$  to  $11\ \mu$  in total length and the daughter spirochaetes from

All the figures were drawn with the aid of an Abbé-Zeiss camera lucida at a magnification of 2000 diameters. Figs. 1-40, various forms of *S. eurygyrata* found in human faeces; Figs. 1-22, loosely coiled type; Figs. 23-35, closely coiled type; Figs. 36-40, forms undergoing transverse fission. Figs. 41-47, closely coiled forms found after exposure to 0.2 per cent. hydrochloric acid; Figs. 48 and 49, showing longitudinal division. Figs. 48-53, spirochaetes from the control in normal saline solution for comparison with Figs. 41-45.

the organisms from different cases and plotting their lengths as a curve. The organism was therefore identified as *S. eurygyrata* Werner, emend. Fantham.

Since a detailed description of this spirochaete has recently been published it will be unnecessary to do more than briefly state the more important characteristics. When alive the organisms were very active, exhibiting lashing, undulatory, and corkscrew movements. The most active individuals were those executing lashing movements and in

$3\mu$  to  $5\mu$ . The number of dividing forms included in the 200 specimens measured was not sufficient to produce a secondary crest on the curve.

Spirochaetes resulting from a recent division might therefore measure from  $3\mu$  to  $5\mu$  in length, and individuals which had reached  $7\mu$  might already be undergoing transverse division, although most commonly this would not happen until they were somewhat longer. The natural size of the organism would appear to be approximately  $3\mu$  to about  $8\mu$ .

TABLE I.—*The Measurements of Length of S. eurygyrata Werner, emend. Fantham.*

For some time after death the spirochaetes continue to be recognisable, although they do not long survive their host. In smears of the intestinal contents made at autopsies about 24 hours after death they are all dead, but still preserve their normal coiled appearance. When stained their bodies are affected somewhat irregularly and give the impression that they are partially degenerated. On one occasion 25 individuals, taken as they came, were measured and were found to average  $5·7\mu$  in length, a figure slightly greater than that for fresh specimens.

#### Geographical Distribution.

So far as I am aware there are no data from which the geographical distribution and frequency of occurrence of *S. eurygyrata* can be determined. There are, indeed, a few references in the literature to the occurrence of spirochaetes or spilla in human faeces, and some of these have been collected by Fantham, but they are of little assistance. It does not appear to be definitely known whether or not they occur in normal or diarrhoeic motions in Europe.

Fantham states that "perhaps even as high as 50 per cent. of the cases examined" by him were infected with these organisms, but most of his patients were soldiers suffering from various forms of dysentery or diarrhoea contracted in Gallipoli or Flanders; many of them must previously have resided or served in tropical countries, and they had probably all been exposed to the chance of infection by contact with other soldiers who had served in the tropics. A few normal persons were also examined, but it is not stated that spirochaetes were found in any of them.

In view of the fact that *S. eurygyrata* appears to be invariably present in the human intestine at Accra on the Gold Coast, West Africa, it would be interesting to know if the infection is equally common in other tropical countries and if it also occurs in healthy persons in Europe.

#### Distribution of the Spirochaetes in the Host.

The fact that the spirochaetes were most easily found after purgation or in persons suffering from diarrhoea suggested that they frequented mainly the upper reaches of the bowel and were swept thence into the large intestine and rectum. A series of preparations made at an autopsy showed that the organisms were present in the stomach, in the small intestine at various points, in the caecum, and in the large intestine, but in this particular case they were not plentiful in any of these situations. In a second case they appeared to be most numerous in the caecum, but were nowhere abundant.

The action of the gastric juice might have been expected to be injurious to such a delicate organism as *S. eurygyrata*, and as evidence obtained from the examination of specimens taken after death is not indisputable some experiments were carried out in the laboratory to determine the action of 0·2 per cent. hydrochloric acid. A small portion of faeces in which spirochaetes abounded was emulsified with the acid solution and kept in an incubator at  $37^\circ\text{C}.$  and simultaneously a control with normal saline solution was made.

The acid had no immediate injurious action on the spirochaetes, but on some occasions appeared to stimulate their activity, and for an hour or two, at any rate, living specimens continued to be present and no sensible difference could be detected between them and those in the controls. It was not easy to be certain that none of the spirochaetes were killed, however, owing to the minute size of the organisms and to the fact that in every sample both immobile and active individuals were present. In one such experiment living spirochaetes were still present in the acid solution after two hours' incubation, and appeared to be just about as numerous as in the controls; but after six hours they had all died, whereas those in the controls were still most lively. By this time evaporation had considerably reduced the volumes of the fluid, a fact which may have been important. Smears were made from these preparations at this stage, and after fixation were stained. In the controls the spirochaetes, which had been extremely active, were found to be loosely or but moderately closely coiled (Figs. 48–53); but in the acid solution they were all unusually closely coiled (Figs. 41–45). Certain other changes appeared to have taken place: many of the spirochaetes were exceptionally thick and Y-forms (Figs. 46 and 47) were common, as if longitudinal division had been active before the organisms died; a number of multiple forms were found, and coccoid bodies were quite common. These changes seemed to indicate that as the solution concentrated the spirochaetes endeavoured to meet the situation by emergency measures.

#### Mode of Infection.

In the case of an organism so widely distributed as we have found *S. eurygyrata* to be there can be no difficulty in the spread of the infection, either directly or by the contamination of food. When exposed to the action of 0·2 per cent. hydrochloric acid in laboratory experiments the spirochaetes did not appear to be injuriously affected, for some hours at any rate; indeed, their activity often seemed to be increased, and at autopsies smears made of the stomach contents showed that they were present in this part of the gastrointestinal tract. Infection from man to man by means of the spirochaetes themselves is therefore a possible and probable event.

The occurrence of spirochaetes in which the cytoplasm had concentrated so as to form granules pointed to another means of dissemination, for these so-called coccoid bodies have been considered to be the cross-infective stage. Fantham (1914 and 1915) believes that *S. bronchialis* is transmitted from man to man by means of these bodies, and although he cannot be said to have proved the fact he has brought forward some evidence in support of it. The same author speaks of them as being "resistant." If, indeed, the granule phase is an integral part of the life-cycle of spirochaetes, as seems most probable, it is a reasonable hypothesis to suppose that they play a part in the dissemination of the organisms. In the lower bowel during the solidification of the faeces, and more particularly when exposed to the air after expulsion, the spirochaetes find themselves in a medium in which their normal active life cannot be continued, and perhaps in consequence proceed to the formation of coccoid bodies. Unfortunately, it is at present impossible to recognise these bodies when freed amongst the innumerable granules found in the faeces, but they are often seen before they escape from the parent spirochaete, and if they are resistant they must be an important factor in transmission, since they might convey infection from man to man through the air, on soiled linen and utensils, and by the agency of flies, &c.

#### The Occurrence of Spirochaetes Resembling *S. eurygyrata* in Various Animals.

Elsewhere I have recorded (1915) the occurrence of a spirochaete resembling *Spirochaeta eurygyrata* in the intestine of a monkey which died of amoebic dysentery in Accra. These organisms averaged a little over  $5\mu$  in length and were indistinguishable from the species found in human beings.

More recently I have examined the faeces of a few other animals—namely, sheep, cattle, goats, pigs, dogs, cats, and rats—and have found in them spirochaetes similar to, if not identical with, *S. eurygyrata*. They did not appear to be pathogenic to their hosts, and I am inclined to regard them as saprophytes. This is not the proper place to describe these organisms in detail, but I may perhaps be permitted to

make a few remarks about them in view of their bearing on the human infection.

Spirochaetes not readily distinguishable from *S. eurygyrata* were found in sheep. Some of them had loosely, others closely, coiled bodies; their ends were pointed, they were very slender, and of 25 drawn with the aid of a camera lucida the shortest measured  $3\mu$ , the longest  $7\mu$ , and the average was  $4.7\mu$ . Very similar, if not identical, organisms were found in cattle, pigs, and goats; but in these animals, when stained preparations were examined, great difficulty was experienced in distinguishing the spirochaetes from other bodies, probably of a vegetative nature.

In rats, both the wild and the albino *Epimys ratus*, intestinal spirochaetes were exceedingly common and were morphologically indistinguishable from *S. eurygyrata*. There is therefore no necessity to repeat the description, but in Table II. a few measurements of length are given in support of my statement.

TABLE II.—*The Measurements in Length of Intestinal Spirochaetes from Man and Various Animals.*

Host.	Number measured	Lengths in microns.										
		1	2	3	4	5	6	7	8	9	10	11
Man ...	200	—	2	38	57	55	31	10	4	2	—	1
Monkey ...	25	—	—	5	10	8	2	—	—	—	—	5.3
Rat ...	50	—	3	8	11	12	4	3	—	1	—	5.0
Sheep ...	25	—	—	3	7	11	3	1	—	—	—	4.7
Cattle ...	25	—	—	8	7	2	3	2	3	—	—	4.7
Goat ...	25	—	—	3	3	8	5	4	1	—	1	5.5
Pig ...	25	—	—	3	6	6	6	2	—	2	—	5.2
Dog ...	50	—	10	23	13	4	—	—	—	—	—	3.2
Cat ...	25	1	11	9	4	—	—	—	—	—	—	2.4

The spirochaetes found in the faeces of cats and dogs appeared to be similar, but they were much more abundant in the latter animals. They were of a type resembling *S. eurygyrata*, but appeared to be smaller. When alive the structure and movements of the organism did not show any characters of specific importance. The spirochaetes were generally loosely but sometimes rather closely coiled; their ends were usually pointed, but in the smallest specimens were more blunt; tangles were seen and specimens showing chromatitic rodlets and coccoid bodies; and individuals undergoing both longitudinal and transverse division were observed. The spirochaetes were slender but varied in thickness. They were usually very small. Fifty individuals from a dog taken as they came and drawn with the aid of a camera lucida averaged  $3.2\mu$  in length, the shortest being  $2\mu$  and the longest  $5\mu$ . Elsewhere in the same film longer specimens reaching  $9\mu$  were, however, found.

These spirochaetes may have been morphological variations of *S. eurygyrata*, but I am inclined to think that they were more probably a distinct but closely allied species. It will be necessary to study their morphology more thoroughly than has as yet been possible before deciding this point.

It is, of course, well known that spirochaetes are common in the alimentary canals of animals. All that the above remarks are intended to indicate is that various domestic animals, including rats, harbour in their intestines and excrete in their faeces spirochaetes that cannot be distinguished by morphological characters from *S. eurygyrata*, the organism which infects man. Whether the various spirochaetes are actually identical or not it is difficult to say; and as they are not definitely pathogenic and as infection is so common both in men and animals at Accra experiments can be of no assistance in this case. This type of spirochaete is evidently widely distributed, and if, as I believe, it is saprophytic there does not appear to be any decided reason why some of the forms found in animals should not be capable of thriving also in the human intestine, in which case they must be an important source of infection to man.

#### Pathogenicity.

As has already been stated, *S. eurygyrata*, in larger or smaller numbers, has been found at Accra in the faeces of every individual, whether European or native, examined for these organisms. As the majority of the persons examined were in a normal state of health, the pathogenicity of this spirochaete must be very slight, if indeed it is at all harmful. Hitherto in West Africa it has been regarded as unimportant but capable of multiplying in a debilitated host or in a diseased intestine to such an extent that it might become a

contributory cause of sickness. In some cases of diarrhoea for which no definite cause could be found spirochaetes have been present in countless numbers. It is hardly possible that under such circumstances they can be entirely benign.

Fantham stated that he has seen the spirochaetes penetrate epithelial scales in the faeces, become quiescent, and produce in them their "resting coccoid bodies." I have not myself seen this occur, but unless the event witnessed by Fantham was an abnormal one it is possible that the spirochaetes penetrate also the cells lining the intestine, in which case their pathogenicity would be indisputable. The organism may perhaps pass through an intracellular phase similar to that which I have recently described as occurring in a urethral spirochaete, but I was not able to discover any evidence of this. The possibility must also be considered of the spirochaete under certain circumstances invading the blood and producing a generalised infection; and in this connexion it may be recalled that *S. icterohaemorrhagiae*, the parasite discovered by Inada (1914) in Weil's disease, is described by Ito and Matsuzaki (1915) as measuring in length from a quarter the diameter of an erythrocyte to five times this length, and is in other respects morphologically a very similar organism to *S. eurygyrata*. The infection in Weil's disease has, indeed, been thought to occur through the alimentary canal (Weil, Fiedler), although the Japanese investigators appear to have favoured a cutaneous route. So far as could be ascertained, the parasites appeared to be merely saprophytic in the cases I have examined, but in the present state of our knowledge the question cannot be considered as settled.

There is one aspect of the effect of a tropical climate that has not hitherto received the consideration which is, I believe, its due, and that is the alteration produced in the intestinal flora and fauna. In their native lands Europeans are habituated to the presence of certain organisms in their intestines &c.; they live, so to speak, in symbiosis with them, and their physiological processes are suitably adapted. In a tropical country they are called upon to readapt themselves to a new set of organisms, and it is possible that much of the ailing and unfitness and many of the obscure effects of "climate" that cannot definitely be traced to meteorological conditions or recognised infections may be due to a failure to cope successfully with this demand. West Africa, for example, is by general consent admitted to have a most unhealthy "climate," and yet the meteorological conditions in many parts of it are not exceptionally bad, and many of the most devastating diseases of other tropical countries are either entirely unknown or but rarely encountered in it. There are, of course other meteorological conditions besides temperature and humidity, other pathological conditions besides those at present recognised, and various social, domestic, and organic factors that have to be considered; and amongst these unidentified influences the alteration in the intestinal flora may, I suggest, have its place. *Spirocheta eurygyrata*, which has been found to be practically always present in the human intestine at Accra, may therefore have some importance if on investigation it is found that this is an exceptional state of affairs.

#### Conclusions.

1. *Spirocheta eurygyrata* Werner, emend. Fantham, is well-nigh an invariable inhabitant of the human intestine at Accra on the Gold Coast, West Africa.

2. Similar, if not identical, organisms are found also in the intestines of various animals.

3. As a rule, the spirochaetes appear to be non-pathogenic—that is to say, their presence is not incompatible with a normal state of health, but under certain conditions they multiply so enormously that it is difficult to believe that they can be entirely benign.

Note.—Since the above was written the study of the intestinal spirochaetes of animals at Accra has been continued and an account of the results has been published in the *Annals of Tropical Medicine and Parasitology*, vol. x., pp. 331-343. It may therefore be of interest to add to what has already been stated that a monkey, a cat, rats, sheep, cattle, goats, and pigs were found to harbour organisms morphologically indistinguishable from *S. eurygyrata* the species found in man. Another advance in the knowledge of the subject is due to Mr. H. F. Carter (*Ibid.*, x., p. 391), who has recently published some remarks on the occurrence of spirochaetes in the faeces of soldiers. He examined both dysenteric and

non-dysenteric patients and found spirochaetes in 56·5 per cent. of the former, and 41·0 per cent. of the latter. These results are of interest when compared with those obtained in West Africa, but it still remains to determine the prevalence of the infection in persons who have resided in temperate regions only.

## Clinical Notes: MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### CASE OF ACUTE DILATATION OF THE STOMACH FOLLOWING GASTRO- JEJUNOSTOMY.

BY FRANK GODFREY, M.B., C.M. EDIN.,  
CONSULTING SURGEON, SCARBOROUGH HOSPITAL.

I RECENTLY operated on a patient, aged 23 years, who presented symptoms of pyloric obstruction, dating back for about four years. I found very marked stenosis of the pylorus, with scarring of an old prepyloric ulcer, and a moderately dilated stomach. There was also a diseased appendix bound down to the caput cæcum by old adhesions. I did a posterior gastro-jejunostomy, making the opening specially large, because of the increased size of the stomach, and removed the appendix. Beyond rather frequent vomiting, the patient showed no symptoms to cause anxiety for the first two days. She had nothing given by the mouth save small quantities of hot water and a little weak tea. On the third day the vomiting became more frequent, small quantities of watery fluid being thrown up, the pulse-rate increased, and the temperature fell to below 98° F. The patient complained of great weight in the abdomen, and she rapidly became "pinched" and collapsed. I then found a huge fluctuating tumour on the left side of the abdomen, extending down nearly to Poupart's ligament. Fearing that it was the transverse colon, which had possibly been returned twisted on itself, I opened the abdomen and found an enormously distended stomach, which I emptied. The contents were watery fluid, and represented in amount far more than the patient had had to drink. She died almost immediately.

Examination showed the gastro-jejunostomy opening to be patent, of large size, and perfect, and there was no discoverable "kink" or other obstruction in the efferent limb of the attached gut, which was empty.

I can only account for the condition as a paresis in a stomach weakened by chronic dilatation. Sir Berkeley Moynihan, to whom I related the case, told me that he had not met with a parallel one, but that he was told that exactly the same thing happens in animal experiments. One regrets that the deceptive vomiting and absence of serious symptoms prevented an earlier recognition of the condition.

Scarborough.

### CASE OF INFLAMMATION IN A PERSISTENT PATENT MECKEL'S DIVERTICULUM SIMULATING APPENDICITIS.

BY ROBERT M. GLOVER, F.R.C.S. EDIN.,  
ACTING SURGEON, ROYAL INFIRMARY, DUMFRIES.

THERE are no diagnostic distinctions between this form of diverticulitis and acute appendicitis. But immediate operation is necessary in acute appendicitis, and if the comparatively rare condition of acute diverticulitis (Meckel) is present it can be recognised and dealt with.

The patient, aged 27, was admitted to the Dumfries and Galloway Royal Infirmary on July 19th, 1915. He was referred to me by Dr. M. Bryson, Thornhill, with a diagnosis of acute

appendicitis. There was a history of seizures on several occasions, each one being typical of acute appendicitis. On the present occasion he had apparently suffered from a similar attack, and Dr. Bryson advised immediate operation.

On examination the patient presented the usual signs and symptoms of an acute suppurative appendicitis, except that localised abdominal tumidity and tenderness were situated rather higher and nearer the middle line than usual. These points, of course, would not impress one that the case was other than an acute suppurative appendicitis with the appendix probably pointing upwards and inwards, and my own diagnosis therefore agreed with that of Dr. Bryson.

At operation, a few hours after admission, I opened into a localised abscess cavity with an extension downwards towards the pelvis, and faecal-smelling, dark-coloured pus at once escaped. When the pus had been removed I observed a long tube lying free in the abscess cavity. The tube was about 7 inches long, rather thicker than an average appendix, had no mesentery, and originated from the ileum. About 1 inch from its intestinal origin it was dilated to the shape and size of a tangerine orange. The bulbous part was gangrenous, black in colour, stippled with greyish points. The intestinal ostium of the tube was about 1 inch in diameter. Distally the tube tapered away to a thin fibrous cord which disappeared backwards amongst adhesions. I did not identify the appendix, as I thought it unwise to disturb adhesions in any attempt to do so. But without doubt I was dealing here with a persistent, patent, inflamed, and gangrenous Meckel's diverticulum. I removed the diverticulum. The wall of the tube was quite sound for about half an inch from the bowel, and so the opening could be securely closed.

Recovery was uneventful, the patient being discharged from hospital in three weeks.

On examining the tube afterwards the dilated part was found to be full of thin fluid faeces, and the greyish points on the outer surface corresponded in position with small faecal concretions adherent to the inner surface.

It was fortunate that a localised abscess had formed here. If that had not occurred, and operation had been at all delayed, rupture of the dilated part with copious extravasations of faeces would certainly have eventuated, and, according to statistics quoted by Jacobson, few of such cases recover—as might be expected.

Dumfries.

## Medical Societies.

### ROYAL SOCIETY OF MEDICINE.

#### SECTION OF OPHTHALMOLOGY.

*Exhibition of Cases.*—*Fur Infection of Human Conjunctiva from Cats.*—*Retinal Signs of Arterio-sclerosis Compared with those of Increased Blood Pressure.*

A MEETING of this section was held on Feb. 7th, Mr. WILLIAM LANG, the President, being in the chair.

Mr. G. HARTRIDGE showed a drawing of a case of Probable Rupture of the Optic Nerve. The patient, a member of the Royal Flying Corps, suddenly fainted while flying and remembered nothing more until five days later. An observer said that in the last 500 yards of the fall the machine was vertical, and it was smashed. The airman sustained serious damage to the left arm and right eye. Apparently there was no skull injury. When seen three weeks after the accident extensive subconjunctival haemorrhages were found in both eyes. In the right eye there was no perception of light, the pupil was widely dilated, and the vitreous was so filled with blood that no details of the fundus could be seen. There was a small wound of the upper lid. A small probe revealed no foreign body. The vision of the left eye was 6/5; fundus normal.—The PRESIDENT mentioned a similar case in a boy who had a clothes-prop poked into his eye.—Lieutenant-Colonel R. H. ELLIOT commented on the surprising escape of the patient from death, which was probably due to the brunt of the fall having been taken by one of the wings of the machine. He saw one man whose machine fell 150 feet, and all that could be seen was slight ecchymosis of the conjunctiva, and his pilot said he believed he had sprained his ankle!

Mr. H. B. GRIMSDALE showed a case of Congenital Absence of Choroid.

Mr. ARNOLD LAWSON read a paper on Fur Infection of the Human Conjunctiva from Oats, giving an account of three cases. The first patient was a girl of 15 years, who had a pet Persian cat which she fondled a great deal. One

day, after burying her face in its fur, her eyes became suffused and she had a severe sneezing fit. The next day the eyes were swollen, and a purulent discharge was exuding. The nostrils were also swollen, and purulent sanguineous matter was issuing from them. Cultures were made from the child's discharge and from the cat's fur, and *Staphylococcus aureus* was found in abundance. Energetic treatment resulted, without permanent damage to the eyes. The cat was, of course, destroyed. The second case was that of a boy aged 14 years, and was complicated and severe. A fortnight before Mr. Lawson saw the boy he had swelling of the left eye, and of the glands of the neck, the local practitioner diagnosing mumps. It did not run the usual course of mumps; there had been no fever or pain. When seen there was a brawny swelling over the parotid and into the neck, and the lids of the left eye were considerably swollen, with inflammation of the conjunctival surface of both tarsi. A muco-purulent discharge was exuding from the furrows of the swollen tissues. Tuberle seemed improbable on account of the rapidity of the development. The boy had been in the habit of walking about with his pet Persian cat perched on his left shoulder and cuddling it. The patient was anaesthetised and the condition treated by cutting, scraping, and swabbing with 2 per cent. silver nitrate. Six weeks' treatment was required and the glands did not subside for three months. The scrapings were cultivated and revealed *Streptococcus longus*, *Streptococcus brevis*, and *Staphylococcus albus*. A dog in the house and the cat were examined, and the latter was proved to be the culprit. The third, and most severe, case was that of a girl aged 5 years, who was staying with friends at a farm. She developed muco-purulent conjunctivitis of a mild type after nursing a favourite cat, which divided its attention between the house and a cowshed. After a time the neck glands were involved in a serious degree. The upper lid showed an exuberant mass of cock's-comb granulations, especially on the retro-tarsal tissue. He suspected conjunctival tubercle. He cut and scraped away all the infected parts, and treated the residue with mitigated nitrate of silver stick. An excellent recovery ensued after three small operations in the course of the next three months. There had been no recurrence in eyes or glands. Mr. Browning pronounced it to be the bovine type of tubercle bacillus. Scrapings injected into a guinea-pig resulted in rapid wasting, and death within a fortnight. The owners refused to allow the cat to be examined. Mr. Lawson pointed out how great a danger cats were in this respect, especially among children, though, because of its habit of licking itself, and thus distributing its saliva, it was popularly regarded as a cleanly animal.—Mr. M. S. MAYO remarked that tubercle was a common disease among cats.—Dr. ETTIE SAYER referred to a case of tuberculous infection of the eye from a pet dog.

Mr. P. C. BARDSLEY read a paper on the Retinal Signs of Arterio-sclerosis Compared with those due simply to Increased Blood Pressure. The late Mr. Marcus Gunn, in Vol. XVIII. of the Ophthalmological Society's Transactions, published his great work on the retinal signs of arterio-sclerosis, and since that date but little had been added. The four cardinal signs therein laid down were: (1) a tendency to tortuosity of the arteries, especially smaller vessels; (2) variation in the calibre of the vessels, especially sudden diminution over a short length; (3) alteration of the normal light streak, which became brighter and more sharply defined; and (4) indentation of veins. Sometimes the changes developed rapidly, especially after influenza, scarlet fever, or other toxæmia, vision being at the same time reduced to 6/12. Mr. Bardsley said he could not believe that advanced fibrosis could have occurred in a day or two. Lowering of the blood pressure brought about an improvement in the appearance and cessation of the headaches which accompanied the high pressure. He submitted that the following were the indications of simple high tension without real arterio-sclerosis: (1) the vessels appeared to be uniformly distended; (2) the light reflex was broadened out, and might apparently reach the whole width of the vessel; (3) the light streak was increased, but did not look like silver wire; and (4) the tight arteries indented the veins deeply in very high tension, leading to back pressure. He concluded by pointing out the pitfalls of which persons unskilled in the use of the ophthalmoscope might not be aware.—Mr. HERBERT PARSONS referred to the recent work on the subject by Mr. Foster Moore.—Mr. J. B. LAWFORD said

he was a colleague of the late Marcus Gunn when he was making investigations. Since that time his observations convinced him that the prognosis in these cases was not always as bad as Mr. Gunn considered. He had seen a number of cases—some of them having been under Mr. Gunn's care—get much better. There were ophthalmoscopic changes, not very different from those of arterio-sclerosis, which had not nearly the same grave significance as those of the actual disease.—Mr. D. LEIGHTON DAVIES said that in examining a number of old people in Cardiff Workhouse he was struck by the very slight signs of retinal arterio-sclerosis. The most pronounced and constant sign was redness of the disc. He seldom saw any marked indentation of veins, although the systolic pressure was often over 200 mm. and the diastolic 140 mm. He found it very difficult to give a prognosis as to the duration of life in these cases.

## Reviews and Notices of Books.

### *Formes Cliniques des Lésions des Nerfs.*

By Mme. ATHANASSIO-BENISTY. Paris: Masson et Cie. 1916. Collection Horizon. Pp. 240. Price 4 fr.

A PREFACE by Professor Pierre-Marie introduces the author of a well-written and useful treatise on nerve injuries. Commencing with a brief description of the methods used in a routine neurological examination of a limb, the various forms of injury met with in their clinical aspects are systematically described, the text being fully illustrated by numerous excellent photographs and diagrams. A further second volume on treatment and restoration of function of nerves is promised as a sequel.

We note that in the description of the examination of nerves by electro-diagnosis of the paralysed muscles no mention is made of the use of condenser currents, which has recently become a favourite method with several practitioners in this country, who assert that it provides a more accurate and certain means of determining the exact condition of the damaged nerve than the older and well-tried methods of faradism and galvanism. A sound chapter is devoted to the discussion of painful injuries of the nerves, when reference is made to the fact, well known to all who have worked in neurology during the present war, that the median and internal popliteal nerves suffer particularly in this way. The author suggests as accounting for this fact, that the palm of the hand and the sole of the foot are the cutaneous areas supplied by these two nerves, and that they are the two areas above all others which are liberally provided with touch corpuscles and similar end-organs for sensory stimulation. These painful affections of the hand and foot were named by Weir-Mitchell long ago "causalgia," and over the derivation of the word the author's Greek fails her. The burning pain in the hand, with bursting tearing sensation in the finger-ends, is well described, as are also the accessory factors that will start or aggravate the paroxysms of pain, such as dry heat, scraping noises, coughing, sneezing, laughter, and most sudden emotions, Madame Athanassio-Benisty omits to mention what in our experience is the worst enemy of sufferers from causalgia—in military hospitals, at least—namely, the gramophone. The pain usually reaches its maximum some few days or weeks after the injury, though some pain dates from the moment of the wound. The hand or foot often sweats profusely and is hot and reddened, or even cyanotic, while the application of cold water and keeping the limb raised relieve the pain. Atrophy of the whole hand, skin, muscles, and the finger pulps, with incurving bridged nails are evidences of the trophic damage, while skiagrams exhibit an osteoporosis of the bones of the hand or foot. This painful trophic condition never occurs with severe lesions of the nerves, and anaesthesia is always very slight if present, while operations on the damaged nerves have shown only slight compression by fibrous scar or congestion and oedema of the nerve. Surgical interference rarely relieves, though alcohol injection of the nerve above the lesion may give excellent results. The pathology of the condition has been suggested to be due to an associated vascular lesion in the arm or leg, but this cannot be the case, for injuries at a distance from any vessel of importance may produce the disease. The author considers that we may be dealing with a neuritis of the sympathetic branches accompanying the nerve-

trunks. The lesions of the brachial plexus are fairly fully dealt with as regards motor and sensory paralysis; nothing is, however, said of operative procedure. This, in our experience, is rarely of any real value in injuries of the plexus from bullet wounds, owing to the large amount of scar-tissue which cannot be prevented from re-enveloping the nerves.

Full accounts are given of the anatomy of the sciatic nerve and its injuries, with excellent figures of the cutaneous nerve-supply of the lower limb, while lesions of the lumbosacral plexus and a description of cranial nerve injuries complete a useful and carefully written volume.

#### *Care and Feeding of Infants and Children.*

By WALTER REEVE RAMSEY, M.D., Associate Professor of Diseases of Children, University of Minnesota, U.S.A. With 123 illustrations. London and Philadelphia : J. B. Lippincott Company. 1916. Pp. 290. Price 9s.

This work is primarily written for nurses, but, in this country at least, it is well adapted for use by average health workers, and among them it should become popular, for the reason that greater notice is given to the preventive side of medicine than to the curative. Pathology, diagnosis, and treatment by drugs find little place in this volume; but when occasion warrants, sufficient attention is paid to these scientific aspects of medicine to make the rationale of professional management clear to the nurse.

The lines of management suggested in these pages agree very closely with those now taught in our well-conducted welfare centres; and the author shows himself to be commendably free from fads and fancies, but by no means adverse to the giving of "tips," if the expression is permissible, for nursing and sick-room technique. His suggestions for improvising means for collecting specimens of urine in the case of young infants, for strapping the protuberant umbilicus, for the breast-feeding of weakly infants, and so on, are excellent. We cannot, however, agree with his view that an adherent foreskin had better be left alone in the hope that it will right itself. There are naturally degrees and varieties of adhesions, but the *laissez-faire* policy is not a good one. On page 55 we notice views on the question of mouth-breathing in infants to which we cannot altogether subscribe. The author claims that mouth-breathing in quite young infants is due to the presence of a large post-pharyngeal tonsil. We submit that it very seldom starts in this way; in young infants the adenoids are more often the necessary consequence of mouth-breathing. The author, in our opinion, greatly understates the possible sequelae of painful dentition. He says the teeth are always growing, therefore exacerbations of symptoms are wrongly ascribed to teething; but if there is one thing that is quite clear about the growth of teeth it is that it is subject to pauses and periods of accelerated development. On page 87 we notice the old fable that during the siege of Paris infant mortality was low; recent evidence proves that the mortality during this time of anxiety was enormous. In more than one connexion the author refers to the condition of tongue-tie as if it were an abnormality due to peculiarities in the growth of the frenum linguae; surely the shortness of this fibrous structure is generally, if not always, due to some incapacity on the part of the infant to extrude the tongue—namely, in some want of neuromuscular coöordination. If the tongue can be, and is, properly extruded the frenum grows in accordance with the requirements. These are, however, minor matters, and on the thoroughly good common sense and rational advice offered for the management of infants and children we congratulate Professor Ramsey.

#### *Clinical Bacteriology and Haematology for Practitioners.*

By W. D'ESTE EMERY, M.D., B.Sc. Lond. Fifth edition. London : H. K. Lewis and Co. 1917. Pp. 310. Price 9s. net.

THE late Sir Michael Foster once warned a friend never to write a text-book, as "if it is a success, it is a millstone around your neck for the rest of your life." Dr. Emery will assuredly carry his millstone so long as he continues to provide the practitioner with the lucid and up-to-date information contained in this book. In this edition he has gone a little beyond what the peace-time practitioner requires, and has included such things as Dreyer's method of agglutination with the Oxford Standard Cultures and McIntosh and Fildes's method of complement fixation; this is a good departure, as it is

wise for every medical man to understand the principle of these important tests. It is also open-minded, as Dr. Emery does not himself believe that it is necessary to add complement at all for the Wassermann reaction. Many recently qualified men have acquired a turn for laboratory methods which will, it may be hoped, never leave them, and they will find these inclusions of considerable service to them. The value of a book of this kind opens up indeed an interesting question of medical politics. The surgeon uses the operating theatre, speaking roughly, as his workshop to verify the opinions given in the consulting-room, and the physician of the future will do something to equalise his opportunities if he has a handicraft of his own. Probably this was in Sir Clifford Allbutt's mind in winding up a recent discussion on the relation between physician and surgeon. Dr. Emery's book is an excellent guide to the physician's handicraft. *rec*

## New Inventions.

### IMPROVED APPARATUS FOR INTRAVENOUS INJECTION.

WHAT is known as the "military" apparatus for intravenous injection has met with much favour. It has, however, some minor disadvantages, which are, I think, remedied in the modification shown below.

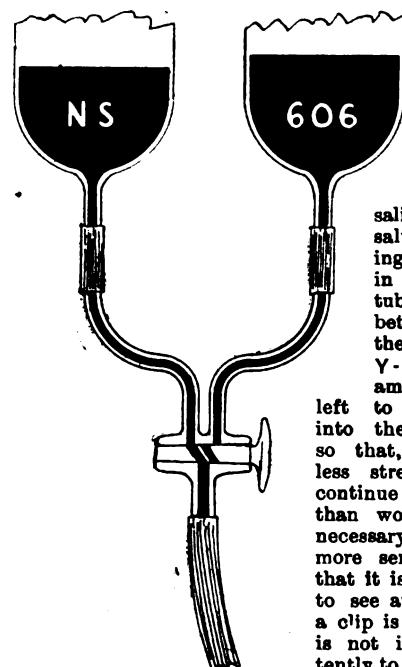

In the usual arrangement the two graduated barrels for normal saline and salvarsan respectively are connected with the arms of a glass Y-piece by two lengths of rubber tubing each bearing a metal clip.

When the dose of salvarsan has been run off from its barrel, one closes the clip of that side and opens the other to let the normal saline wash out the salvarsan still remaining in the tube. But in the portion of tube that intervenes between the clip and the junction of the Y-piece a certain amount of salvarsan is left to diffuse gradually into the flowing saline; so that, to get a colourless stream, one has to continue the saline longer than would otherwise be necessary. A second, and more serious, objection is that it is by no means easy to see at a glance whether a clip is open or closed. It is not impossible inadvertently to leave both open at once—an accident which will, if the levels of the liquids in the barrels are different, lead to a mixture of the two fluids, with the result that the whole of the material will be wasted.

To overcome these difficulties I had a special glass Y-piece made with a three-way tap at the junction. The arrangement will be easily understood from the diagram, which shows both fluids as dead black. In the position illustrated the normal saline is flowing. It is evident that if the tap is turned through two right angles the saline will be cut off and the salvarsan will flow. In any intermediate position both are cut off. Mixture of the two fluids is thus impossible. Then when the change from salvarsan to saline is made, there is no reservoir of salvarsan to contaminate the saline. There is besides a small gain in the fact that one movement effects the change of fluids.

An experience of some months convinces me that this little device, which has been made for me by Messrs. Baird and Tatlock, Charles-street, Hatton Garden, E.C., does, to an appreciable extent, make for efficiency and convenience; and I therefore think it worth description.

LONDON: SATURDAY, MARCH 3, 1917.

## The Mobilisation of the Medical Profession.

FROM previous articles which have appeared in these columns it must be apparent to our readers that a very important, if not critical, position has been reached in the medical profession with regard to the supply of doctors for the Army. At least three months ago it became obvious to many that the question whether the medical profession should or should not mobilise itself voluntarily was urgent, and how rightly the situation has been gauged was proved more recently by the statement of the Prime Minister, who, when speaking of the responsibility now lying upon the whole population for active prosecution of the war, intimated that where voluntary mobilisation in any section of that population did not fulfil expectations compulsory powers would have to be sought. The intention of the present Government to ensure that every man in the country during these our critical times should give his help, how, when, and where best qualified was thus openly avowed. Therefore, and immediately on the creation of the National Service Department, Mr. NEVILLE CHAMBERLAIN, the Director-General of that Department, was approached by the Central Medical War Committee, the Committee of Reference of the English Royal Colleges, and the Scottish Medical Service Emergency Committee with a view to an early interview. It was felt that a joint representation should be made as promptly as possible to the Director-General by the three statutory bodies upon whom the double duty had devolved of keeping up the necessary supply of medical officers for the Navy and Army and of watching lest the civilian population should be dangerously depleted of professional assistance. In the event the Scottish body was not present at the interview, which was duly granted, but the Director-General has since been placed in possession of its opinions.

Early in February Mr. NEVILLE CHAMBERLAIN made a statement as to the direction in which his plans might be expected to mature, so as to obtain from the general population services of all kinds, and in the course of this statement, referring to medical men, he said: "We have to see that the doctors are so mobilised and distributed that the needs of both the civil population and the Army can be met, and that, so far as possible, specialists can be put to do the work for which they have taken pains to fit themselves." This was to a great extent the object which the three statutory bodies had set before them, and it was felt generally that Mr. NEVILLE CHAMBERLAIN could practically carry out his plan of campaign, as far as the medical profession was concerned, by availing himself of the existing organisations, with their considerable experience and accumulated stores of information. The Director-General of

the National Service Department has now written to the three statutory bodies saying that as the organisation of the medical profession, with a view to meeting the needs both of the military and civil population is one with which his department is concerned, he desires to have a conference with their representatives. "Up to the present," he adds, "the work of providing the Army with qualified medical men has been undertaken by the Central Medical War Committee with the assistance of the Committee of Reference for England and Wales and the Scottish Medical Service Emergency Committee. It is clear, therefore, that in considering what further steps should be taken these bodies should be consulted and their opinions fully considered. Accordingly, I have decided to call a conference comprising three representatives of the Scottish Medical Service Emergency Committee, four from the Central Medical War Committee, and two from the Committee of Reference, over which I have asked Sir DONALD MACALISTER, the President of the General Medical Council, to preside." The statutory bodies are asked to nominate representatives from amongst their number to attend the conference, when the problems that have been presented frequently in these columns will be discussed, beginning with the vital question of whether the service to be rendered by members of the medical profession should be voluntary or compulsory. The three statutory bodies have pronounced so far in favour of the view that sooner or later some form of compulsory arrangement will be found to yield the best and fairest results.

At a conference held recently of the committee and the secretaries of the Local War Committees for Scotland a resolution was adopted unanimously affirming that further substantial calls are likely to be made on the medical profession which can only be met by mobilising the whole profession. But the issues in Scotland are less complicated than they are in England, where the redistribution of medical men, centrally or locally, must often be a matter of extreme difficulty. The financial aspects of national service for medical men in many parts of England will require very careful handling, whether we consider whole-time or part-time work; and the sacrifice of the medical man who holds a commission with its dangers and emoluments must be fairly compared with that demanded of the civilian medical man under all forms of substituted practice. Because the considerations that will here arise are so many and may be so delicate, we welcome Sir DONALD MACALISTER as chairman of the Conference proposed by Mr. NEVILLE CHAMBERLAIN. The President of the General Medical Council has acquired by his long connexion with the Council an unrivalled knowledge of our professional life, and in any discussion under his guidance no room will be found for irrelevancies, while the minimum of time will be spent in explanations of the unimportant, or repetitions of the well-known. It is hoped that there will emerge from the Conference a plan of campaign and the necessary authority to secure its working.

## The Restitution of the War Cripple.

As the war drags on, and the possible shortage of supplies of all other kinds gives rise to anxiety, the supply of maimed and crippled men continues unabated and the problem of their restitution becomes a larger and larger one. Something of the magnitude of the problem has now been realised by the authorities, and the chief stumbling-block to its effective solution lies in the conflicting destinies of the two main groups of disabled men: those whom treatment can restore to efficiency as a fighting unit, and those whose military value no longer exists but whom it would be base ingratitude not to restore to the highest possible grade of civilian efficiency. Stated thus on paper, the division appears to be a precise one, and one for which arrangements could readily be made, dealing with the group of disabled but restorable soldier in the military hospital and convalescent camp, and providing immediate discharge of the non-restorable soldier for treatment and re-education as a civilian worker. In practice the distinction has so far been found quite impossible to make. Many apparently minor conditions prove unamenable to treatment and lead to ultimate discharge from the Service, while grave disabilities—short of blindness, deafness, and injuries requiring amputation—under patient and appropriate treatment have not prevented a return to military efficiency. Nor has the difficulty of distinguishing the two groups been attended with any serious drawback to either class. Whatever the ultimate result of treatment may prove to be, the same medical care, the same physical means, and the same moral control are the curative factors in both cases. Further than this, the particular methods of manual training desirable for civilian efficiency have been increasingly found to be more curative than ingenious exercises designed to produce the correct quality and quantity of muscular movement, but devoid of useful concrete results. The apparatus may be physically perfect; the manual training has psychic factors which are essential.

Take, for example, the life of a man who has to stay some months in a Command Depôt after his wound or his shock has allowed him to leave the Military Hospital. He rises at 6.30 A.M. and goes to bed at 10 P.M. or later. His treatment may occupy half an hour daily, his physical training another half hour, route-marching an hour more towards the latter part of his stay. Much spare time remains for the flesh and the world, if not the devil, to appropriate. How can this man's time—whatever his immediate future—be better employed than in learning something which will be useful to himself and his country, provided, of course, that the learning does not interfere with his treatment? The problem is one that has had to be faced in all combatant countries, and it may not be amiss to record the official German attitude, as shown in the remarks of a lecturer at a course of military medicine at Düsseldorf. "We could not," he says, "have foreseen in peace times the tremendous importance of employing, besides purely medical methods, special means to occupy the sick and wounded in

hospital in order to accustom them again to work and send them back more readily to their occupation. Repeated and detailed instructions have been issued on this point. The sick and wounded are not to be discharged from the Service until they have reached the highest possible degree of recovery of function. In view of the prolongation of treatment thus entailed it is essential to protect the inmates of hospital beds from long months of idleness which may make them more or less work-shy, quite apart from the fact that in many cases appropriate manual training is directly designed to assist their cure and to assure the attainment of what I may term the social aim of treatment. Experience shows that many men require a certain external pressure to keep them at actual work, even though this is light. The appearance of compulsion must, of course, be avoided, and the aim be to lead them by easy stages to more useful and arduous work, finally bringing them to the point of finding real enjoyment in their recovery of working ability." The important work of the Military Hospitals Commission in Canada, recorded in the Third Bulletin,<sup>1</sup> dated December, 1916, emphasises the same essential point of view. The disabled Canadian is to be made, physically and mentally, as efficient as possible while still under military oversight.

Such being the essentials for the war cripple's restitution, there must be some well-considered reason for the issue of an Army Council instruction to discontinue workshops and the teaching of trades and occupations in military hospitals, camps, and dépôts, an instruction which was—as we noted last week—described by Lord H. CAVENDISH-BENTINCK in the House of Commons as a retrograde and reactionary step. It is impossible that the Army Medical Service does not recognise the value of such workshops and teaching, and the explanation can hardly be other than that the provision of these essential things in some different way is in contemplation. Methods and technique require some backing of authority and discipline to be fruitful of result, and discipline must remain an essential part of any effective scheme. The statement and recommendations just issued by the Committee of Council of the Section of Balneology and Climatology of the Royal Society of Medicine, which we print on p. 348, come at an opportune moment. The committee express the hope that the problem is now approaching a solution. They see the necessity of an adequate and well-ordered system of physical treatment for every disabled soldier before his discharge from the Service. They regard physical treatment as the thing most needed to prevent the formation of an army of cripples in this country. And they recommend the establishment throughout the country of centres of physical treatment on an adequate scale and wherever possible in association with general hospitals, so that other forms of special treatment and diagnosis may be readily available, and in close association with centres of re-education. Whatever the solution decided upon the problem brooks no delay.

The total number of students in attendance in May, 1916, was 6103. The total number of students in attendance in January of this year was 6682.

### THE ULTIMATE RESULTS OF SANATORIUM TREATMENT.

ALTHOUGH the War has deprived the King Edward VII. Sanatorium at Midhurst of its medical superintendent and its pathologist, partial compensation, as the report for the year 1915–16 shows, has been provided by a grant made on the recommendation of the Medical Research Committee in aid of the statistical researches carried out at the sanatorium. As is well known, the primary difficulty in regard to all extensive statistics of sanatorium results is that so many patients are lost sight of after the first year or two following on their treatment. With the employment of a special officer to follow up these cases the gratifying result has been achieved that a greater number have been traced in the last year than at any time previously. This has the curious result in the tables that more patients of a certain past year are "well" or "alive" in 1916 than was the case in 1915 or 1914. An improved system of investigation has redeemed them from the ranks of the "lost sight of" and has thus enhanced the reputation of the treatment they had received. Taking the first complete year, 1907–08, in which the sanatorium had its full complement of patients, and tracing the history of the 206 patients discharged during this period whose sputum gave positive result in the sanatorium, 71 were known to be "well" or "alive" in 1913, and 70 of these were still alive in 1916. Picturing this result in the form

of a curve we note that the numbers still living in each successive year after discharge rapidly fell for five years, to remain level for the next years, and, we may presume, indefinitely. The observation is practically the same whatever the severity of the disease was at the time of treatment. Naturally a smaller proportion of the advanced or Group 3 cases survived, but the deaths occur within five years of discharge, and the statistics suggest that after having survived his course of treatment for five years the tuberculous patient has a good prospect of continuing to live indefinitely, whatever was the condition of his lungs at the time of his cure.

### THE INTRAVENOUS ADMINISTRATION OF QUININE.

UNTIL the extermination of the mosquito is complete quinine must continue to hold its place in malarial countries as a prophylactic and curative agent, and in cases in which it is not tolerated by the stomach, or it is desired to obtain an immediate and powerful effect, the intramuscular or intravenous administration has to be considered. Intramuscular injection is painful and may give rise to points of local necrosis, but is generally held to be safer than the intravenous route, although in either case the injection of tetanus spores should not be lost sight of. Speaking from a very large experience amongst African troops during 1915, M. Braun, director of the Maroccan Service de Santé, states<sup>1</sup> that ampoules containing 0·4 gm. of quinine hydrochloride in 1 c.c. of excipient, being non-isotonic and caustic, are liable to cause abscess at the site of intramuscular injection. Baccelli, who employed intravenous injection with much success in pernicious cases of malaria, used a solution made up as follows: Quinine hydrochloride, 1 gm.; sodium chloride, 0·75 gm.; distilled water, 10 gm. Apparently the fear of producing clotting in the vein is the chief drawback to this method, and in a paper<sup>2</sup> by Captain A. C. MacGilchrist, I.M.S., this risk is fully considered, as well as the possible production of haemoglobinuria. Captain MacGilchrist concluded by advising a very dilute solution for intravenous use—viz., 7 grains of bi-hydrochloride in 2 to 3 pints of saline fluid. The work of three physicians, Dr. German Arellano, Dr. F. G. Miranda, and Dr. Fausto Robleto, at the San Juan de Dios Hospital in Granada, Nicaragua, suggests that Baccelli was right and that concentrated solutions of quinine can be injected safely into a vein. They have gone even further and find that the solution need not even be isotonic with the blood serum. Dr. Arellano and his colleagues speak of being daily confronted during the rainy season with rapidly fatal forms of pernicious malarial fever,<sup>3</sup> and have found nothing so efficacious in the face of impending death as the intravenous injection of quinine. Concerning its administration they write:—

The first time that we employed this method with the happiest and most successful results, we were able to use Parke Davis and Co.'s solution of quinine in sodium chloride and other salts; but unable to obtain the isotonic ampoules, we had no choice but to use the acid non-isotonic solutions of the chloride, bichloride, and chlorhydro-sulphate of

<sup>1</sup> Le Paludisme au Maroc en 1915, Arch. de Méd. et de Pharm., November, 1916.

<sup>2</sup> THE LANCET, 1911, i., 1221.

<sup>3</sup> Whitaker's Almanack, with unconscious humour, gives the population of Nicaragua as 620,000, "of whom about three-quarters are mixed Indian and the rest Indians, besides the Mosquitos, who are mostly in a savage state." [The italics are ours.]

quinine, as supplied in ampoules by Parke Davis and Co., Clin of Paris, and others, diluted with an equal volume of warm sterile water. The results are simply marvellous and we have never had the least trouble or accident. So sure, safe, and efficient do we consider this method to be that we employ it now even in cases showing no signs of perniciousness. The patients merely complain of tinnitus, deafness, transient nausea, and a sense of heat spreading all over the body within one to ten minutes after the withdrawal of the needle.

In all cases of pernicious fever we have found the worst symptoms, such as amaurosis, convulsions, algidity, and collapse, to disappear from three to six hours after the injections, though cases have occurred in which the patient was out of danger within the hour. The dose we employ is from 10 to 25 or even 50 centigrammes, according to the age, state, condition, and symptoms of the patient. Children are also subjected, when the veins are accessible, to the same treatment. In fact, in children it works wonders. Now, as it may be asked why we have not used Baccelli's formula, we will frankly state that in this town there are no pharmacies really reliable in which such solutions might be aseptically prepared, a fact which has led us to give preference to solutions which, acid though they be, are most certainly aseptic and exactly dosed. The technique we employ is as follows: We mix the solution within the syringe with an equal amount of sterile warm water, taking care that no precipitate or coagulum is formed as the blood comes in contact with the solution. It has been observed at times, especially when time is lost in inserting the needle, that a kind of flocculent precipitate is formed very similar to that of "aluvine" when injected intravenously; but, as in that case, experience has shown it to be perfectly safe, it being a sort of emulso-suspenoid.

The authors add that at first their procedure was severely criticised by their local colleagues, and in the daily press, until continued experience showed its safety. They offer no explanation of the non-coagulability of the blood by the acid non-isotonic solution, but commend other workers to test the fact for themselves.

#### INTESTINAL OBSTRUCTION DUE TO ASCARIDES.

Dr. J. M. Perret and Dr. H. T. Simon have reported in the *Journal of the American Medical Association* of Jan. 27th a case of intestinal obstruction due to a very unusual cause—a mass of round worms. During the latter half of the nineteenth century opinion was divided as to the possibility of *ascaris lumbricoides* being the cause of intestinal obstruction. Thus, Leichtenstern and Sir Frederick Treves opposed this view, while Troussseau, Bretonneau, and Stutz upheld it, each having been among the first to report cases. Bordoroni and Stepp in 1887 reported two cases, both of which were confirmed post mortem. Simon in 1892, while holding a necropsy in a case of intestinal obstruction, found the cause to be a mass of round worms. Botoff in 1897 reported a case of obstruction, perforation, and peritonitis, in which the necropsy revealed the presence of 500 round worms. An American surgeon, Van Meter, reported the case of a child, aged 5 years, with a sausage-like mass above and to the left of McBurney's point in which operation revealed in the lower part of the ileum a coil of round worms causing complete obstruction. The patient recovered. In this country Mr. D. H. Vickery reported the case of a woman with symptoms of intestinal obstruction and a history of vomiting several round worms. After a dose of santonin, followed by castor oil, she vomited 12 round worms. The symptoms of obstruction disappeared, and excepting for the sudden termination of gestation she made an uneventful recovery. Dr. Perret and Dr. Simon report the following case. A girl, aged 8 years, was sent to hospital for operation with the diagnosis of acute intestinal obstruction. The family history was of interest, as the patient's five sisters and brothers had passed round worms on many

occasions. The child herself had frequently passed round worms since the age of 2 years. Five days prior to admission she was seized with a pain in the right lower abdominal quadrant, accompanied by slight elevation of temperature. On the second day she began to vomit clear watery fluid, and this continued up to the time of admission. A dose of castor oil was given the second day, but only a small stool was passed. On admission the temperature was 101° F. The child was poorly developed and nourished. The skin was of a slight sallow tint. The glands in neck and groin were enlarged. The eyes were sunken, with dark hollows under the orbits. The tongue was dry and coated. Coarse mucous râles were heard over the lower half of the right lung, both anteriorly and posteriorly. The abdomen was distended and tympanitic. In the left lower abdomen, in the region of the sigmoid, a mass the size of a large lemon was felt. An enema was given, and returned coloured with faecal matter and containing a mass the size of a child's closed fist consisting of approximately 40 round worms, coiled and interwoven together. A second enema was given, and returned highly coloured with faecal matter. The distension was relieved, and excepting for a rise in temperature for 8 hours the patient improved, and in 12 hours the temperature was only 99.6°. She continued to improve, and except for an acute bronchitis, which she developed about the seventh day, recovery was uninterrupted. Most cases of intestinal obstruction due to round worms have been diagnosed at the necropsy or on the operating table. Only seldom has the mass of worms been expelled through the natural channels, as in the present case.

#### PROHIBITION AND THE DRINKING OF METHYLATED SPIRIT IN RUSSIA.

IN recent discussions on the drink question reference has frequently been made to certain untoward results which are alleged to have followed the prohibition of the sale of vodka in Russia, the most serious of these results being the increasing use, in lieu of the prohibited beverage, of such dangerous substitutes as methylated spirit and varnish. The extent to which this pernicious practice has developed is, from the nature of the case, somewhat difficult to determine, but that it is sufficient to justify considerable anxiety is clear from the rise in the number of deaths from alcoholism in the larger towns, and also from the increasing frequency of cases of toxic amblyopia due to methyl alcohol poisoning since the enforcement of the new policy. In his "Self-Discovery of Russia" (Constable and Co., 1916) Professor J. Y. Simpson quotes some striking data referring to both these points from a report on "The Results of Compulsory Prohibition and New Forms of Drunkenness," made by Dr. Alexander Mendelson to the Russian Society for the Preservation of National Health in March, 1915. Dr. Mendelson gives the number of deaths from alcoholic poisoning in the Obukhov City Hospital of Petrograd for the several months from July, 1914, to March, 1915, as follows: 52, 25, 27, 29, 33, 46, 56, 53, 36. The higher rates in the later months coincide with a great increase in the sale of denatured spirit and with a rise in the number of methyl alcohol drinkers in the hospitals. In the Eye Hospital in Petrograd there were treated 72 cases with impaired vision due to this specific

cause from July, 1914, to April, 1915. Previously such cases had been quite insignificant in number. Dr. Mendelson, who is a strong supporter of the prohibition policy, is of opinion that methylated spirit-drinking is practically confined to persons who were already of confirmed alcoholic habits, but this view appears to be disputed by other medical authorities. Thus, in the Russian Supplement of the *Times* of July 28th, 1915, extracts are given from an article contributed to the *Russky Wratch* by Dr. Novosolsky, in which the writer affirms that the use of methylated spirit and other substitutes is spreading amongst all classes of the population who formerly drank vodka, and this opinion appears to be in some measure confirmed by the observation that the alcoholics treated at the Obukhov Hospital for methyl alcohol and varnish drinking include persons of all ages and professions. The Russian Government is fully alive to the danger of this new drug habit, and is endeavouring to combat the evil by bringing the sale of denatured spirit under stricter control and also by adopting more effectual methods of rendering such spirit unfit for use as a beverage, but no evidence is as yet available to show to what extent these measures have proved successful.

#### THE PROGNOSIS OF GUNSHOT WOUNDS OF THE ABDOMEN.

LAST year at the Swiss Surgical Congress Professor Sauerbruch narrated his surgical war experiences in Germany, and as the text of this lecture has now come into our hands we may expand with advantage the summary<sup>1</sup> already given of his remarks on the treatment of gunshot wounds of the abdomen. Sauerbruch is convinced of the necessity of immediate operative interference in all gunshot wounds of the abdomen in which the peritoneum is involved, and believes that when this necessity is generally recognised the arrangements for carrying out the operations will readily be improvised at the front. He regards the external circumstances—the operation-room and the appurtenances of a theatre—as in general vastly overrated, holding that correct diagnosis, followed by immediate and technically correct operating, is the only factor which seriously counts. He refuses to speak, as is often done, of hopeless operations, in view of the consistently good results of early operation. It cannot be too much emphasised, he adds, that men who recover after abdominal injury retain an undiminished capacity for living and for working and do not swell the ranks of the war cripples. Sauerbruch therefore regards the operative treatment of gunshot abdominal wounds as precisely the most encouraging field of action for the military surgeon.

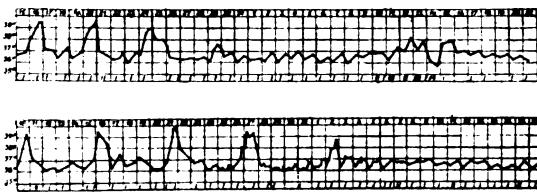

#### IDIOPATHIC DISLOCATION OF THE EYEBALL.

Dr. David M. Greig, of Dundee, records in the *Edinburgh Medical Journal* (Vol. XVIII., No. 2) a case of idiopathic dislocation of the left eyeball in a female child aged 11 months. The child was a neglected and badly nourished child weighing only 7 lb. There was no proptosis except when the child had screaming fits. Both eyes were then proptosed, the left more than the right, and on these not infrequent occasions the left eye often became dislocated forwards between the lids. It could not be retracted voluntarily, but was easily replaced by gentle pressure. Dr. Greig has been

unable to find any record in the literature of spontaneous dislocation of this nature, but we doubt if it is quite so rare as the absence of published cases would seem to indicate. In cases of extreme proptosis accompanying exophthalmic goitre dislocation forwards between the lids occurs very readily, and the same is true in some cases of oxycephaly, in which the orbits are very shallow. We have seen cases of this type of dislocation associated with very slight traumatism, where, indeed, the injury has been so trivial that one is inclined to attribute the displacement to the effects of sudden fright. In our experience these cases have always occurred in children; there has been practically no injury to the eye, which has been replaced in the orbit with the greatest ease.

#### ANOTHER SPIROCHÄTAL DISEASE.

EARLY in 1916 a febrile disorder was described by Werner and Haenseler as occurring on the German Eastern front, and named by them five-day fever or febris quintana, and by later observers febris wohynica. In the summer of 1916 a number of similar cases occurring on the Western front were known as Meuse fever. A paper by Dr. W. Thörner in the *Münch. med. Wochenschr.* for Dec. 12th last gives a concise account of the disease with two charts—which we reproduce—showing

the characteristic course of the temperature. Put briefly, the characteristic symptoms are: Sudden elevation of temperature without rigor, and defervescence without sweating; acute pain in the legs often requiring morphia, but without definite evidence of periostitis; an enlarged spleen sensitive to pressure; heart, lungs, digestion, and urine normal; polynuclear leucocytosis up to 20,000. The symptoms described need not be reproduced in greater detail, as they correspond exactly to the description of trench fever on our own front given by Dr. A. F. Hurst in THE LANCET of Oct. 14th last. The resemblance between the temperature charts given by the different authors is very striking. The German observers have devoted much attention to discovering the exciting cause of the fever. Werner thought he saw on one occasion a spirochete rather longer than the diameter of a red cell. Korbsch saw dancing cells and a suggestion of moving filaments amongst them. Töpfer observed short rods. Professor Riemer, who summarises these observations in the *Münch. med. Wochenschr.* for Jan. 16th, has now found spirochaetes very scanty in direct films, but fairly abundant after anaerobic culture for a week in blood serum. He gives micro-photographs showing an organism scarcely longer than the diameter of a red blood cell, with four turns, exceedingly mobile and difficult to see unstained, but readily taking up any anilin dye and decolorising with Gram. Some of the spirochaetes were longer, with a middle piece between the turns as though two spirals were intertwined. Attempts to infect guinea-pigs with the organism were unsuccessful, and Professor Riemer is too cautious to

<sup>1</sup> THE LANCET, 1916, I., 634.

assert that he has discovered the causal agent of the disease, although he believes that he has done so. The analogy with relapsing fever is evident. If his observations are confirmed, trench fever must be added to the rapidly growing list of spirochaetal diseases. Dr. Galli Valerio, from the Lausanne Hygienic Institute, has recently enumerated them as syphilis (*S. pallida*), yaws (*S. pertenuis*), relapsing fever (*S. obermeieri* and others), Weil's disease (*S. icterohaemorrhagiae*), bronchitis of Castellani (*S. bronchialis*), angina of Plaut-Vincent (*S. vincenti*), pyorrhcea alveolaris (*S. dentium* and others), and various spirochaetes associated with local venereal ulcerations. In our present issue Dr. J. W. Scott Macfie gives an account of another spirochaete (*S. eurygyrata*), an apparently harmless inhabitant of the human intestine on the Gold Coast. On all counts spirochaetosis is a subject of growing importance.

THE Hunterian lecture announced to be given before the Royal College of Surgeons of England by Captain Frank Cook, R.A.M.C., M.B., B.S., F.R.C.S., on Gunshot Wounds of Joints, their Pathology and Treatment, will be read in the theatre of the College to-day (Friday), at 5 o'clock P.M. by Professor Arthur Keith. The lecture will be illustrated by specimens from the War Office collection.

THE Morison lectures will be delivered by Dr. Edwin Bramwell, F.R.C.P. Edin. & Lond., before the Royal College of Physicians of Edinburgh, on Monday and Friday, March 5th and 9th, at 5 o'clock P.M. each day. The subject chosen by Dr. Bramwell is Neurology of the War; the first lecture will deal with Gunshot Wounds of the Peripheral Nerves, and the second with Shell Shock and the Effects of Head Injuries.

#### THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

A MEETING of the Executive Committee of this Fund was held on Feb. 22nd at THE LANCET Offices, when a printed statement was presented of the progress and working of the Fund during its first two years. The method of distribution of the statement was agreed upon by the Committee for, owing to the expense of paper, postage, and labour, it was not considered a fair demand on the resources of the Fund to send copies to all subscribers.

A communication was read from the London Branch of the International Relief Committee stating that it should be possible to continue to transmit the monthly grant of £800 to the Belgian medical organisation as now had been done for some time through Mr. Herbert Hoover, for in Mr. Hoover's absence the work of relief was still proceeding on the same lines.

The financial statement showed that the contributions since Dec. 15th, 1916, had amounted to £176, of which £147 had been received from the Royal College of Physicians of Edinburgh as a final contribution. £2400 had been sent to Belgium since the same date.

The Fund has received through Dr. William B. Coley and Dr. William K. Draper, acting as a committee of the New York Academy of Medicine, the sum of £13212s. 5d.

#### PHYSICAL TREATMENT FOR DISABLED SOLDIERS.

STATEMENT AND RECOMMENDATIONS BY THE COMMITTEE OF COUNCIL OF THE SECTION OF BALNEOLOGY AND CLIMATOLOGY OF THE ROYAL SOCIETY OF MEDICINE.

1. The serious and urgent problem of the physical treatment and training of disabled and discharged soldiers has been a long time under discussion, and it may be hoped is now approaching a solution. The committee, having devoted more than two years to an investigation of the subject in England and France, feel bound to reassert their profound conviction, already twice urged in reports to the War Office (August 28th, 1915, and Feb. 18th, 1916), that physical treatment, so often advocated by them, is now the thing most needed to prevent the formation of an army of cripples in this country. What has been already done here and there only points the way to the much larger aim of the committee, and that is to provide an adequate and well-ordered system of physical treatment for every disabled soldier throughout the country who needs it, as far as possible before his discharge. Such physical treatment consists of hydrotherapy, electrotherapy (including radiotherapy), mechanical treatment, medical gymnastics, and massage.

2. At the British spas large numbers of wounded have received treatment by waters and baths, although considerable difficulty and delay in obtaining this treatment is sometimes experienced. The number of invalids requiring such treatment is likely to increase, and the committee are of the opinion that the hospital accommodation for soldiers at the spas should be reserved for cases requiring hydrological treatment.

3. The committee are further of opinion that as the importance of systematic methods and records is becoming more and more apparent, the general adoption of one simple system of recording cases is most desirable, in order that the records supplied from all centres of physical treatment, whether at spas or attached to hospitals, may admit of exact classification.

4. A clinic for the physical treatment of disabled officers was opened at 126, Great Portland-street, London, W.. in July, 1916, as a result of the efforts of certain members of this committee. The intention of the promoters of this clinic was to provide an institution, thoroughly well equipped, which would afford to officers who were patients in the various hospitals in London the combination of the different forms of physical treatment which seemed necessary. Those responsible for it have endeavoured with some success not only to combine the best methods of treatment but to secure the accurate keeping of measurements and records. It is not a copy of any existing institution, and embodies some new features, such as the "whirlpool" and "sedative pool" baths. The clinic is now financed by the British Red Cross Society, and is called "The Red Cross Clinic for Physical Treatment of Disabled Officers." Officers of all the Allied nations are treated free of charge under careful and constant medical supervision. It is a matter of satisfaction to the committee that so much excellent work in physical treatment is now being done at certain of the command depôts, convalescent camps, military hospitals, and Red Cross hospitals. The experience already obtained clearly indicates the possibilities of such treatment when properly applied.

5. The vocational re-education of disabled soldiers in the British Islands, so far as it exists at present, has been in many instances carried out without medical supervision, and not associated with any concurrent physical treatment nor with any systematic measurement of the patient's disability and progress. The committee cannot regard this as satisfactory. On the other hand, they know that excellent re-educational work under medical supervision has been already accomplished at the Military Orthopaedic Hospital at Shepherd's Bush and at certain of the command depôts.

The senior honorary secretary reports as the result of a visit just paid to certain centres for physical treatment and training in France, under both the French and Belgian Governments, that the arrangements for industrial, intellectual, and agricultural re-education are being continually extended in that country, and are in every case under medical direction. Essential importance is attached by French experts to the combination of re-education with physical treatment. The committee notice with much

interest that these facts have been set forth very clearly by Sir Henry Norman in his recent report to the War Office on the Treatment and Training of Disabled and Discharged Soldiers in France.

They would only add that, in their opinion also, physical treatment should in the great majority of cases be provided as an integral part of re-education; and that the determination of a man's capacity for work ought not to depend on casual observations, but on the results of the periodical measurement of his progress by means of accurate instruments. The very important economic and financial aspect of this matter are outside the province of the committee.

#### *Recommendations.*

1. That a service of physical treatment consisting of hydrotherapy, electrotherapy (including radiotherapy), mechanical treatment, medical gymnastics, and massage, should be made available at the earliest possible date for all soldiers needing it who are disabled by war.

2. That centres of physical treatment, comprising all the above methods, should be established throughout the

country on an adequate scale, and wherever possible in association with general hospitals, so that other forms of special treatment and diagnosis may be readily available.

3. That at such centres there should be a uniform system of measurements and records.

4. That centres of re-education and centres of physical treatment should be closely associated.

5. That all centres of physical treatment should be under medical direction, with periodical inspection, and that medical men who are experts in the various departments of physical treatment should be appointed to the staff.

6. That at the centres first established instruction in methods of physical treatment should be provided for the use of medical practitioners, medical students, and assistants.

(Signed) WILLIAM GORDON,  
President of the Section;  
SEPTIMUS SUNDERLAND,  
Chairman of the Committee;  
R. FORTESCUE FOX,  
J. CAMPBELL MCCLURE,  
Hon. Secretaries of the Committee.

Feb. 24th, 1917.

## URBAN VITAL STATISTICS.

### VITAL STATISTICS OF LONDON DURING JANUARY, 1917.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 4·0 per 1000 of the population, estimated at 4,310,000 persons in the middle of the year; in the three preceding months the rates were 5·4, 5·0, and 3·9 per 1000 respectively. The lowest rates in January were recorded in Kensington, Hammersmith, Hampstead, Holborn, the City of London, and Wandsworth; and the highest rates in Paddington, Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, and Greenwich. The prevalence of scarlet fever showed no variation from that recorded in the preceding month; this disease was proportionally most prevalent in Fulham, Chelsea, St. Marylebone, Bethnal Green, Stepney, Bermondsey, Lewisham, and Woolwich. The Metropolitan Asylum Hospitals contained 800 scarlet fever patients at the end of the month, against 1117 in 1916, and 913 at the end of the three preceding months; the weekly admissions averaged 95, against 160, 131, and 95 in the three preceding months. Diphtheria was rather more prevalent than in the preceding month; the greatest proportional prevalence of this disease was recorded in Paddington, Stepney, Poplar, Southwark, Bermondsey,

and Greenwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1543 and 1420 at the end of the two preceding months, had further declined to 1202 at the end of January; the weekly admissions averaged 68, against 209, 187, and 143 in the three preceding months. Enteric fever also showed a slightly increased prevalence; of the 36 cases notified during the month, 7 belonged to Stepney, 5 to Wandsworth, 4 to Hackney, 2 to Kensington, 2 to the City of Westminster, 2 to Battersea, 2 to Camberwell, and 2 to Deptford. There were 36 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 39, 42, and 37 at the end of the three preceding months; the weekly admissions averaged 6, against 7, 7, and 5 in the three preceding months. Scarlet fever was proportionally most prevalent in Bethnal Green, Poplar, Southwark, Bermondsey, and Deptford. The 21 cases of puerperal fever notified during the month included 3 in Bethnal Green, 3 in Stepney, 2 in Fulham, 2 in Poplar, 2 in Lewisham, and 2 in Woolwich. The 70 cases of cerebro-spinal meningitis included 7 in St. Pancras, 6 in Islington, 5 in the City of Westminster, 5 in Lambeth, and 4 each in Paddington, Fulham, Hackney, southwark, Wandsworth, and Woolwich; and of the 10 cases of poliomyelitis 2 belonged to Islington and 2 to Lambeth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several metropolitan boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the five weeks ended Feb. 3rd the deaths of 7591 London residents were registered, equal to an annual rate of 18·4 per

\* Including membranous croup.

1000; in the three preceding months the rates had been 12·0, 14·5, and 22·8 per 1000. The death-rates during the month ranged from 14·5 in the City of London, 14·6 in Wandsworth, 15·1 in Hampstead, 15·5 in Lewisham, and 15·6 in Woolwich, to 21·4 in Chelsea, 21·8 in Southwark, 22·1 in Paddington, 23·1 in Finsbury, and 25·0 in Holborn. The 7591 deaths from all causes included 335 which were referred to the principal infectious diseases; of these, 151 resulted from measles, 6 from scarlet fever, 57 from diphtheria, 19 from whooping-cough, 9 from enteric fever, and 93 from diarrhoea and enteritis among children under two years of age. The lowest death-rates from these diseases in the aggregate were recorded in Hammersmith, Kensington, Fulham, Hampstead, Stoke Newington, and Lewisham; and the highest rates in St. Pancras, Bethnal Green, Southwark, Bermondsey, Lambeth, Camberwell, and Greenwich. The 151 deaths from measles were 15 in excess of the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in St. Pancras, Holborn, Bethnal Green, Southwark, Bermondsey, Lambeth, and Woolwich. The 6 deaths from scarlet fever were 16 fewer than the corrected average number, and included 2 in Stepney and 1 each in Kensington, Islington, Bethnal Green, and Wandsworth. The 57 deaths from diphtheria were 9 below the corrected average; of these 8 belonged to Stepney, 6 to Lambeth, 4 to Wandsworth, 4 to Camberwell, 3 to St. Pancras, 3 to Poplar, 3 to Deptford, and 3 to Greenwich. The 19 fatal cases of whooping-cough were 70 below the corrected average, and included 4 in Islington, 3 in Lambeth, 2 in Finsbury, and 2 in Shoreditch. The 9 deaths from enteric fever were 7 below the corrected average, and included 2 in Hackney and 1 each in Paddington, Hammar-smith, St. Marylebone, Islington, Battersea, Camberwell, and Lewisham. The 93 deaths from diarrhoea and enteritis among children under 2 years of age were only 4 below the average; the greatest proportional mortality from this cause was recorded in Paddington, Kensington, Chelsea, Shoreditch, Bethnal Green, Southwark, Lambeth, Camberwell, and Deptford. In conclusion, it may be stated that the aggregate mortality in London during the month from these principal infectious diseases was 21·4 per cent. below the average.

(Week ended Feb. 24th, 1917.)

**English and Welsh Towns.**—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18,000,000 persons, the annual rate of mortality was equal to 21·0, against rates steadily increasing from 16·2 to 22·5 per 1000 in the five preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 21·8, or 1·4 per 1000 less than that recorded in the previous week; in the remaining towns the rates ranged from 11·9 in Walthamstow, 12·2 in Edmonton, and 13·0 in Stockport, to 29·5 in Brighton, 30·3 in Bournemouth, and 34·7 in Gloucester. The principal epidemic diseases caused 336 deaths, which corresponded to an annual rate of 1·0 per 1000, and included 161 from measles, 65 from infantile diarrhoea, 52 from diphtheria, 50 from whooping-cough, and 4 each from scarlet fever and enteric fever. The deaths from measles showed a further increase on the numbers in the four preceding weeks, and caused the highest annual rates of 1·8 in Wimbledon and in Southampton, 2·1 in Dudley, 2·2 in East Ham, 2·6 in Ilford, and 4·2 in Wigan. The 813 cases of scarlet fever and the 148 cases of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 7 and 11 in excess of the numbers at the end of the previous week. Of the 6974 deaths from all causes in the 96 towns, 245 resulted from violence. The causes of 83 of the total deaths were uncertified, of which 16 were registered in Birmingham, 11 in Liverpool, and 5 in Manchester, but only 1 in London.

**Scotch Towns.**—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death rate was equal to 19·6, against 17·9 and 20·1 per 1000 in the two preceding weeks. The 425 deaths in Glasgow corresponded to an annual rate of 19·9, against 21·8 per 1000 in London, and included 18 from whooping-cough, 16 from measles, 7 from diphtheria, 5 from infantile diarrhoea, and 1 each from enteric fever and scarlet fever. The 137 deaths in Edinburgh were equal to a rate of 21·5 per 1000, and included 3 from measles, 2 from whooping-cough, and 1 each from scarlet fever and diphtheria.

**Irish Towns.**—The 205 deaths registered in Dublin were equal to an annual rate of 26·8, or 0·4 per 1000 below that recorded in the previous week, and included 8 from infantile diarrhoea, 6 from measles, and 1 from whooping-cough. The 235 deaths in Belfast were equal to a death-rate of 31·2, and included 7 each from measles and infantile diarrhoea, 2 each from whooping-cough and diphtheria, and 1 from enteric fever.

**THE LATE DR. JOSEPH LAWSON.**—The death occurred at Hove on Feb. 18th of Dr. Joseph Lawson, who in the early days of his career was an assistant physician at Dr. Steevens' Hospital, Dublin. He was educated at Trinity College, taking the degrees of B.A., M.B. in 1868 and the L.R.C.S.I. in 1867. For many years he resided in Yorkshire, where he was medical officer of health at Hebden Bridge. Dr. Lawson, who was 70 years of age, had been living in retirement at Hove.

**BRIGHTON AND THE INDIAN WARRIORS.**—Official announcement was made at the meeting of the Brighton corporation on Feb. 22nd that the Indian Council had sanctioned an expenditure of £750 on the proposed monument to be erected on the South Downs at Patcham, where the bodies of Sikh and Hindu soldiers who died in the Indian hospitals at Brighton were buried, and towards the cost of maintaining it in perpetuity. The corporation had already voted a like sum (£750), and Mr. Austen Chamberlain, in his letter to Sir John Otter, ex-mayor, who took the initiative in the scheme, says that his council will not object to increasing its contribution to £1000 if the decisions taken as to design and material involve an outlay exceeding the £1500 already agreed upon.

## THE SERVICES.

### R.A.M.C. NEW HEADQUARTERS.

The headquarters of the Army Medical Service will in future be at Adastral House, Victoria Embankment.

### ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonels to be acting Colonels whilst employed as Assistant Directors of Medical Services of Divisions: R. W. Clements, D.S.O., H. Herrick, T. H. J. C. Goodwin, C.M.G., D.S.O.

Lieut.-Col. H. H. Brown is retained on the active list, under the provisions of Articles 120 and 522 Royal Warrant for Pay and Promotion, and to be Supernumerary.

Temp. Col. F. D. Bird, C.B., reverts to temporary Lieutenant-Colonel on re-posting.

Granted temporary rank whilst employed at the Craiglockhart War Hospital.—As Major: W. H. Bryce. As Captain: W. H. R. Rivers.

Temp. Major S. N. Davis, C.A.M.C., from General List, to be temporary Major.

Capt. H. C. D. Rankin to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Temp. Capt. J. S. Gladwin, C.A.M.C., from a Canadian Infantry Battalion, to be temporary Captain.

Temp. Capt. William James Dobson Smyth to be Lieutenant, and is granted the rank of temporary Captain.

Temporary Lieutenants to be temporary Captains: J. Potter, E. R. Dermer, J. J. O'Kelly, H. Stewart, S. L. Haslett, G. Sutherland, F. G. Heard, D. L. Sewell, W. E. Waller, J. R. Griffith, N. Grace, P. G. Temple, G. T. L. Murphy, D. M. Baillie, C. B. F. Ivy, H. V. Forster, J. Bamforth, E. E. Semmence, G. Hart, D. Smith, J. S. Part, D. J. Clark, G. G. Buchanan, F. M. Davies, J. L. Cochran, R. C. Harkness, G. Jackson, E. W. N. Hobhouse, J. G. Slade, J. W. E. Cole, D. J. O'Brien, E. M. Balthasar, W. W. Halsted, G. E. Anderson, T. F. Moran, W. S. McGowan, J. P. Douglas, T. W. Rutledge, P. G. Leeman, F. H. McCaughey, C. H. Seville, G. F. C. Healy, W. G. Jones, I. Williamson, C. H. C. Byrne, R. W. G. Young, J. S. Crawford, C. E. Sharp, P. Hudson, H. M. Buchler-Hayes, J. M. O'Reilly, H. McW. Daniel, A. P. Hart, A. N. W. Colahan, H. Stobie, R. Nichol, J. E. Cable, B. H. Wood, W. A. Muir, D. S. Steele-Perkins, G. C. Robinson, J. Colgan, A. G. East, W. J. Macdonald, C. S. Read, G. Cranston.

To be temporary Captains: S. Ritson, R. A. Jones, Temp. Lieuts. A. J. Anderson and W. Roche.

To be temporary Lieutenants: E. Ashby, K. J. A. Davis, L. V. Gatt, J. L. H. Paterson, M. C. Irwin, W. G. Cobb, A. F. Campbell, H. N. Webber, D. Mitchell, H. H. R. Bayley, G. W. Anrum, J. Cameron, J. C. Pearce, M. J. Ryan, P. O. W. Browne, G. P. Jones, R. Maclean, D. S. E. Milligan, H. W. Catto, J. Freeman, J. Aylen, R. C. L. Batchelor, G. H. Joseph, C. J. G. Bourhill, D. Anderson, G. F. B. Simpson, J. E. Hatchie, D. C. Ogilvie, W. F. Box, A. R. H. Harrison, A. R. J. Douglas, M. S. Fraser, H. Cardin, temp. Hon. Lieut. N. S. Sherrard, M. Munro, Temp. Hon. Lieut. H. Archer, E. W. H. Cruickshank, W. P. Wippell, R. G. Stirling, J. R. Dick, T. T. M. Dillingham, W. A. Clement.

Temporary honorary Lieutenants of the St. John Ambulance Brigade Hospital to be temporary honorary Captains: S. A. Henry, C. E. S. Jackson, W. Wilson.

Temp. Capt. J. G. Wilson, C.A.M.C., resigns his temporary commission at his own request.

Temporary Captains relinquishing their commissions: A. M. Ross, E. S. Moorhead, C. Banting, C. Gordon, W. A. Brown, J. E. Stacey (on account of ill-health caused by wounds, and is granted the honorary rank of Captain), H. J. Watt (on account of ill-health).

Temp. Hon. Capt. A. G. Wilkins and Temp. Hon. Lieut. P. L. Hope, having ceased to be employed with No. 5 British Red Cross (Anglo-American) Hospital, relinquish their commissions.

Temporary Lieutenants relinquishing their commissions: G. B. S. Soper, F. L. Spalding, H. Bond, C. G. Merrick, W. G. G. Coulter, J. P. Brown, J. S. Leslie, G. S. Robinson, W. E. Taylor, W. Dixon, T. M. R. Waddell, J. McIlraith.

### SPECIAL RESERVE OF OFFICERS.

Lieutenants to be Captains: G. Chesney, A. R. Steven, W. A. Malone, J. Ross, J. C. Preston, A. Johnstone, G. S. Mather, A. F. Cook, A. C. Dickey, W. Griffiths, E. G. Flishe.

To be Lieutenants: G. A. Harrison, A. R. Dingley (from University of London Contingent, O.T.C.), A. T. Woolward, B. Parker (from Dublin University Contingent, O.T.C.), P. A. Buxton, D. C. Bluet.

### TERRITORIAL FORCE.

Lieut.-Col. W. Patterson, Territorial Force Reserve, to be Major (temporary).

To be Acting Lieutenant-Colonels whilst commanding a Field Ambulance: Capts. (temp. Majors) E. A. Houchin, T. B. Levton, A. A. Hingston, P. Mokey, F. G. Dobson, and Capt. A. J. Williamson.

Capt. P. T. Rutherford, from Attached to Units other than Medical Units, to be Captain.

Lieutenants to be Captains: D. Cameron, J. Chalmers, E. McM. Dunlop, A. C. Hepburn, D. Campbell.

Capt. A. W. Falconer is seconded whilst holding a temporary commission in the R.A.M.C.

C. W. Yates to be Lieutenant.

Major (temp. Lieut.-Col.) A. E. Jerman relinquishes his temporary rank on ceasing to command a Field Ambulance.

Lieut. J. M. Orr resigns his commission.

**A MEDICAL HIGH SHERIFF OF DUBLIN.**—At a meeting of the Corporation of the city of Dublin last week, the High Sheriff of the city for 1917, Mr. Myles Keogh, L.R.C.S. Ire., was invested with the chain of office. It is many years since this dignity was held by a member of the medical profession. Mr. Keogh practises as a dentist.

## Correspondence.

"Audi alteram partem."

### THE MICTURITION CENTRE.

*To the Editor of THE LANCET.*

SIR,—In your issue of Feb. 3rd Mr. J. W. Thomson Walker, in an interesting account of the state of the bladder in man after injury to the spinal cord, makes some historical remarks on the micturition centre, which, I think, call for comment. He says—

The work of Gaskell shows that the centre for micturition lies outside the spinal cord, in the hypogastric and mesenteric plexuses of the sympathetic. Müller, applying Gaskell's view, states that after complete separation of the bladder from the cord reflex micturition still takes place.

Gaskell, I am sure, would have energetically rejected the statement that there was no micturition centre in the spinal cord. So far as I know no one who has experimented on the matter in the last 30 years has questioned its existence, although different values have been attributed to it. The existence of an additional centre outside the spinal cord has long been the subject of controversy. Sokownin<sup>1</sup> in 1874 found that stimulation of the central end of one hypogastric nerve, after severance of all connexion with the spinal cord, caused reflex contraction of the bladder, and considered it to be a reflex like that from the spinal cord involving afferent nerve cells. The experiment was taken as supporting the current theory that peripheral ganglia connected with organs acted as reflex centres for them. It was shown by Anderson and myself<sup>2</sup> in 1894, and by myself<sup>3</sup> in 1900, that the reflex did not involve afferent nerve fibres or cells, but was due to the branching of efferent fibres, one branch running to a nerve cell supplying one side of the bladder and the other to a nerve cell supplying the other side. This I spoke of as an axon-reflex. Goltz and Ewald<sup>4</sup> in 1896 found that micturition returned in dogs after removal of the whole spinal cord below the upper thoracic region. Müller<sup>5</sup> in 1901 made experiments similar to those of Goltz and Ewald, but with less extensive removal of the spinal cord, and confirmed their results. Gaskell,<sup>6</sup> in his book posthumously published in 1916, does not (so far as I have seen) make any mention of a micturition centre; he had not at any time made experiments with regard to it. He discusses the origin of peripheral reflexes in the bladder and elsewhere, and adopts the theory that, so far as they occur, they are due to axon-reflexes.

I am, Sir, yours faithfully,

Cambridge, Feb. 21st, 1917.

J. N. LANGLEY.

### ACUTE GASTRIC ULCER.

*To the Editor of THE LANCET.*

SIR,—Between Jan. 5th and Feb. 3rd of this year six cases of acute gastric ulcer (with pronounced haematemesis or melena, or both haematemesis and melena) were admitted to the Connaught Hospital, Aldershot. Only two cases of a similar nature have been admitted during the previous 22 months. Six cases will, of course, prove nothing, and their occurrence at short intervals may well be within the limits of ordinary coincidence; but the contrast between this comparatively large number and previous admissions of the same disease encourages me to speculate whether something more than coincidence might be invoked and to mention publicly the series for what it is worth as an isolated observation, in the hope that others may have noted the same "coincidence" at this or any other time. As a determining factor, mentioned merely on account of its obviousness, I suggest the protracted low temperature experienced over the whole of this period. I need not waste your valuable space with clinical details except to mention that the ages of the men were 29, 32, 34, 37, 38, and 40 respectively; their

<sup>1</sup> Fourth Vers. russischer Naturforscher in Kasan (Summary in Arch. f. d. ges. Physiol., x., 374).

<sup>2</sup> Journ. of Physiol., xvi., 410.

<sup>3</sup> Ibid., xxv., 364.

<sup>4</sup> Arch. f. d. ges. Physiol., lxiii., 362.

<sup>5</sup> Deutsc. Zeitschr. f. Nervenheilk., xxi., 86.

<sup>6</sup> The Involuntary Nervous System (Longmans, Green, and Co.).

length of service varied from 10 days to 20 months; one case may have been of traumatic origin, none of the cases gave a history of previous haematemesis.

Finally, of the two previous cases referred to above, one was aged 35, the other 51. The elder, after repeated haematemesis, died, having existed upon salines for five weeks, during which time operation, which was urgently advised, was persistently refused.

I am, Sir, yours faithfully,

ADOLPHE ABRAHAMS,

Temporary Captain, R.A.M.C.; Officer in Charge Medical Division, Connaught Hospital, Aldershot.

### THE REPORT ON CEREBRO-SPINAL FEVER.

*To the Editor of THE LANCET.*

SIR,—New results of value to bacteriology, gleaned from recent research on identification of meningococci, are recorded in the Third Special Report<sup>1</sup> of the Medical Research Committee, and the general value of this document is enhanced by inclusion of other matters both of clinical and controversial interest. That at the onset of cerebro-spinal fever the same type of organism is always present in the naso-pharynx as is to be found in the spinal fluid is a fact of great value in early diagnosis, and Captain Flack<sup>2</sup> has shown that by plating a naso-pharyngeal swab on the spot it is possible to diagnose atypical cases within 48 hours.

Of less value seems the pronouncement<sup>3</sup> that naso-pharyngeal organisms, giving cultural and fermentative signs of meningococci, are to be rejected as *pseudo-meningococci* unless they conform to the serological reactions of one or other of four types of meningococci, isolated from 32 cases in 1915. Admitted that these types have predominated in epidemics during 1915–16, they do not exhaust the possible number of pathogenic strains. Flexner has isolated at least 32 strains. Two strains isolated by me<sup>4</sup> from spinal fluid were not agglutinated by antisera from Gordon's Types 1, 2, or 3, but were agglutinated by Flexner in high dilutions, and it is surely an accepted principle of medicine that any germ may become pathogenic if tissue resistance be sufficiently lowered. If so, inagglutinable strains should be regarded as potentially pathogenic. My objection to this limitation is its possible influence on treatment. Without access to a laboratory, where the organism might be differentiated into its serological type and if atypical a serum prepared—a matter of time and distance to country practitioners—it is certainly prejudicial to the patient to surmise that the organism must conform to one of four types, or to employ a serum evolved from one of them. The indication is rather to use a multivalent serum, such as Flexner's. Fleet-Surgeon Bassett-Smith<sup>5</sup> found that of 28 naso-pharyngeal strains 27 were agglutinated by Flexner. Of these, 21 were also tested with Gordon's serums 1 and 2. Seven agglutinated to 1 and 13 to 2.

Lastly, this report contains such authoritative confirmation of the theory of cerebro-spinal fever<sup>6</sup> advanced by me in 1915, that I cannot but regret an absence of any endorsement of those preventive measures which should follow the correct etiology. Lieutenant-Colonel M. H. Gordon and Captain Flack<sup>7</sup> accept spread of infection as due to floating droplets of infected naso-pharyngeal secretion from the "carrier," and as influenced by "the degree of bad ventilation or overcrowding obtaining in his immediate environment." Again, Captain Flack<sup>8</sup> confirms my earlier observation, embodied in a report to the War Office on Sept. 27th, 1915, that swabs and plates conveyed some distance on a cold day to a laboratory are liable to be negative. The point is that meningococci die in 30 minutes at a temperature of 62° F.

I have contended that under conditions of fresh air it is impossible for meningococci to pass from throat to throat, and Captain Flack records a new observation on this point—"whatever the form of treatment, a spell of sunshine and dry weather markedly influenced the rate of discharge of carriers."<sup>9</sup> This suggests that fresh air not only prevents

<sup>6</sup> Loc. cit., p. 77.

<sup>7</sup> THE LANCET, 1916, II., 888.

<sup>8</sup> Ibid., p. 62.

<sup>9</sup> Ibid., p. 63.

spread of infection, but also tends to destroy organisms in the throat. Nevertheless, in the report there is no plea for better ventilation of tents, huts, and barracks, although much labour has been expended on construction of steam engines for belching forth antiseptic vapours. To what end? That "carriers," once disinfected, shall return from the clouded atmosphere of the sterile shrine to those unhygienic conditions under which infection arose and was spread?

In all this there is nothing to occasion surprise. For seven centuries bad air was recognised in the etiology of tuberculosis, while fresh air was ignored in prevention. History will always repeat itself, and so to-day nothing short of a miracle will induce our profession to act on the true origin and prevention of cerebro-spinal fever. Yet in conclusion I would suggest that the tendency of special departments of medicine to attenuate wider physiological and clinical concepts into a microscopic field is to be regretted. I am, Sir, yours faithfully,

HALLIDAY SUTHERLAND,  
Harley-st., W., Jan. 20th, 1917. Temporary Surgeon, Royal Navy.

## THE USE OF QUININE INTERNALLY AS AN ANTISEPTIC.

To the Editor of THE LANCET.

SIR.—Eight years ago when called in by a midwife to a case of puerperal septicæmia, after curetting and douching the uterine cavity, I ordered daily douching with weak iodine lotion and internally quinine sulphate 2 gr. combined with acid. hydrobromic. dil. every four hours in water. As the temperature rapidly fell to normal and the discharge became sweet and small in amount I continued its use in such cases with gratifying success and commenced to put all cases of perityphilitic abscess, gall-bladder abscess, and empyema upon it immediately after operation. In cases of infective bone and joint disease, such as periostitis, osteomyelitis, and suppurative arthritis, I ordered quinine immediately upon admission and prior to operation, continuing it afterwards as in the previous cases. As a result I found that the discharge rapidly diminished in amount, becoming thin, inoffensive, and less purulent, the temperature usually becoming normal in a few days, when the quinine can be discontinued. When the quinine was discontinued before the temperature had been normal for several days the discharge was apt to increase in quantity, becoming more purulent and offensive, with a rising temperature. In discharging bone and joint cases in which quinine was administered before operation, the temperature fell to a lower level and the discharge diminished more rapidly than in other cases. During the eight years my annual operative mortality has not exceeded 2 per cent., rarely more than 1 per cent., in general surgical hospital work.

Acting on this experience I have employed quinine in all cases of septic infection since July, 1915, at the Hotel Dieu, Waterloo and District Hospital, the annexe of the Seaford Military Hospital, where I have had control of 50 beds. A large number of cases of infected gunshot wounds, many of which contained necroëd bone, have been treated there under my care. The mortality rate of my surgical operative military cases has been nil during that period on a total of more than 130 cases.

Dr. J. Mitchell Bruce in his "Materia Medica and Therapeutics," 1915 edition, makes the following, among other, statements regarding the action of quinine: (1) Externally quinine is a local antiseptic, and disinfectant to wounds and ulcers; (2) it may be found in the blood within a few minutes of its administration; (3) it diminishes the number of leucocytes in the circulation very greatly; (4) it augments and later paralyses the amoeboid movements of leucocytes; (5) injected into animals in large dose it prevents the occurrence of suppuration. The action appears to me as follows: Quinine internally administered rapidly renders the blood-stream antiseptic, thus retarding the rate of increase, growth, and development of micro-organisms in all parts of the body. The body cells which are manufacturing anti-toxin in response to the toxic stimulation are thus enabled to get the upper hand, and are probably aided by the phagocytes.

I am indebted to Professor E. E. Glynn, of Liverpool University, for two references, the only ones which I can find, on the value of quinine proved experimentally.

(1) Wilson,<sup>1</sup> who concludes that "The administration of 15 grains of quinine to healthy students seemed to cause a slight increase in their opsonic index," and that "quinine sulphate *in vitro* has an inhibitory effect on phagocytosis in strong solutions, but apparently a stimulating influence in dilutions from 1/15,000 to 1/1,000,000"; and (2) Th. Grün-pan,<sup>2</sup> "Ueber den Einfluss von Chininlösungen auf die Phagocytose," who states that a 0·002 per cent. quinine solution led to a relative increase in phagocytosis of a carmine solution in a rat, but a 0·1 per cent. of quinine solution was injurious to phagocytosis.—I am, Sir, yours faithfully,

VINCENT J. GLOVER, M.D. Liverp..

M.B., Ch.B. Vict.,

Medical Officer of Health, Waterloo and Seaford; Honorary Surgeon, Waterloo and District Hospital.  
Feb. 15th, 1917.

## LIQUOR RESTRICTION AND CASUALTIES.

To the Editor of THE LANCET.

SIR.—It is interesting to note how drunkenness amongst working classes affects the hospital casualty rooms. This is the main casualty hospital in the borough of Bootle and round about, draining from a large "labour" population. The casualty room is open day and night, and I, having the unfortunate honour of being in charge, especially on Saturdays, have noticed how often I had to attend to these "merry-making accidents." Before the present regulations I would not dream of retiring to bed before 1 or 2 A.M., as the casualty room was very frequently visited by customers of public-houses or those who suffered through them. Lately, gratifying to see, it is seldom that we come across a person in such a state. The usual question of a constable, "Is it delirium tremens, doctor?" to detain him over the week-end, is almost forgotten.

Without exaggeration I can safely say that these casualties are reduced to 40 per cent., if not less, whereas other "unavoidable" cases remain the same. I have not had a case of intoxication as a cause of other injuries in the wards for a long time. Further, this hospital, being situated in the midst of a thickly populated area, we used to be troubled at night with "music, mirth, and revelry" outside, but audible in every ward; this no longer exists. I am writing to know, as expected, if other house surgeons thus placed have noticed the same incidence, for surely it could not be the Bootle people only who have so suddenly and marvellously changed into temperance.

I am, Sir, yours faithfully,

D. RAM THAPAR, M.B., Ch.B. Edin.  
Borough Hospital, Bootle, Feb. 26th, 1917.

## THE FIRST SCHOOL FOR MOTHERS.

To the Editor of THE LANCET.

SIR.—If only for the sake of historical accuracy, may I be permitted to point out that your correspondent, Dr. J. E. Sandilands, in his letter in your issue of Feb. 17th, is as incorrect in his facts as to which was the first school for mothers in England as was the writer of the article whose statements he criticises. As a matter of fact, Winchester has no better claim to have started the first school for mothers than St. Pancras. Although opinions may differ as to the exact definition of a school for mothers, there can be no doubt that the special kind of infant welfare work started in Winchester in November, 1906, had been in progress in at least a dozen other towns for some considerable number of years before that date. If Dr. Sandilands would care for details, I can give them to him, but I think he will find sufficient evidence on this point in a paper I read at the National Conference on Infant Mortality held in Liverpool, 1914, and published in the report. No society or institution can claim to be a school for mothers without an infant consultation, for this is the pivot round which all its teaching activities revolve. The first welfare centre to have an infant consultation was that of St. Marylebone. Its schools of mothercraft were started in February, 1906, under the name of the Borough of St. Marylebone Health Society, and its Infant Consultation opened its doors on May 10th, 1906.

The opening of the St. Pancras School for Mothers was inaugurated on July 1st, 1907, at the St. Pancras Town

<sup>1</sup> Amer. Journ. Physiol., 1907, xix., 450.

<sup>2</sup> Centralbl. f. Bakter. und Parasit. Infekt., 1908, Bd. xlvi., 445.

Hall. I have in my possession the printed bill inviting the attendance of the public, so that there can be no doubt as to the date; but, as a matter of fact, St. Pancras was not, I believe, even the second in the list of schools for mothers. Although the St. Pancras school is in no way entitled to the claim of being the pioneer school, there is no question that in propaganda work this London borough deserves the greatest credit. But Winchester has no claim either to have been the first school for mothers or a pioneer in instructing mothers.

I am, Sir, yours faithfully,  
ERIC PRITCHARD.

London, W., Feb. 25th, 1917.

## THE DIFFERENTIATION OF HEART MURMURS IN SOLDIERS.

To the Editor of THE LANCET.

SIR,—I beg to offer a few remarks on this subject before it passes from review, as I have had it under observation for several years and am, perhaps, in a position to throw some further light on it. I gave a brief account of the murmurs in question in 1913,<sup>1</sup> and a somewhat fuller one under the title of the "Soldier's Heart" last year.<sup>2</sup> In the latter I pointed out that "in many cases the murmurs subside under firm pressure of the chest-piece of the stethoscope against the thoracic wall and return under a lighter touch," and suggested that the apparent vigour of the heart's action and increase in the force of the apex beat, together with diffusion of its area, are due to deficiency or absence of the normally intervening cushion of lung, while firm pressure on the ribs, inhibiting the megaphonic effect of vibration, at once reduces the sounds to their actual value, which is characteristic of deficiency rather than increase of energy, such as obtains in hypertrophy. I have observed the occurrence of the same phenomenon during accesses of paroxysmal tachycardia and its subsidence as soon as the action of the heart returns to its normal frequency. As far as I am aware, it has not as yet been recorded that similar acoustic results may in like manner be elicited in simple dilatation of the aorta, whether due to atony or inflammation, and will assist in differentiating that condition from the early stage of aneurysm.

Up to the time of the war my observations were mainly made on public school boys, and in a less degree on the more mature subjects to be found among undergraduates, who had sustained dilatation of special incidence on the right heart as the result of long-distance running or boat-racing. Subjects whose cardiac and arterial walls have been weakened by toxæmia, mostly of alimentary origin, are specially prone to develop such murmurs. As Professor Drummond insists they are quite distinct from those due to dilatation of the orificial rings and from cardio-respiratory bruits. His observation that in some cases they are audible only when the patient is lying on his left side is new to me, but it seems to support the explanation which I have offered. In any case, their inconstancy and variability stamp them, in common with all murmurs dependent on or largely influenced by posture, as not being of organic origin.

I am, Sir, yours faithfully,

W. BEZLY THORNE.

<sup>1</sup> Proceedings of Royal Society of Medicine, 1913, vi., 93-97.

<sup>2</sup> Practitioner, May, 1916.

HARVEIAN SOCIETY OF LONDON.—Mr. J. Ernest Lane will deliver the Harveian lecture on the Treatment of Syphilis at the Stafford Rooms, Tichborne-street, Edgware-road, W., on Thursday, March 22nd, at 8.30 P.M.

Mrs. Tubby, the wife of Colonel A. H. Tubby, F.R.C.S., consulting surgeon with the Forces, has received the bronze medal and certificate of the Royal Humane Society for the gallant rescue from drowning of two Egyptian ladies.

NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES.—At a meeting held at 1, Wimpole-street on Monday last it was decided to establish a London and Home Counties Branch of the National Council. Lord Sydenham, who presided, stated that the branch was to be entirely independent of the National Council, which would assist it in every possible way, retaining the censorship of all literature issued. An executive committee of 30 was appointed representing the various medical, social, and administrative bodies concerned.

## The War.

### THE CASUALTY LIST.

The following names of medical officers appear among the casualties announced since our last issue:—

#### Killed.

Lieut. C. Stiebel, I.M.S., was educated at Clifton and at Cambridge, and was a student at St. Thomas's Hospital, London, qualifying in 1902. He had held appointments at the West London Hospital, at Bradford Infirmary, and at St. Marylebone Infirmary, afterwards proceeding to India to work as a medical missionary, and later joined the Indian Medical Service. On the outbreak of war he went to Alexandria and afterwards to the Dardanelles and to Mesopotamia.

Capt. J. E. Milne, D.S.O., R.A.M.C., was educated at Aberdeen University, and qualified in 1891. He joined the R.A.M.C. in October, 1915, and was awarded the D.S.O. for gallantry on the Somme. Prior to joining the Army he had a large practice in Aberdeen.

Capt. J. A. Harper, R.A.M.C., attached Yorkshire Regiment.

#### Died of Wounds.

Capt. E. W. S. Martin, R.A.M.C., attached Worcester Regiment, was educated at Queen's College, Belfast, and qualified in 1899. He was in practice in the Rhymney Valley of Monmouthshire, where he held several public appointments, prior to the outbreak of war, and after joining up he went to Malta and afterwards to Mesopotamia.

Capt. J. R. Macallan, R.A.M.C., attached East Lancashire Regiment, qualified in 1910 at Glasgow.

#### Wounded.

Capt. F. E. Chapman, R.A.M.C.  
Capt. C. O'Brien, R.A.M.C.

### DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

Second Lieut. G. S. Cooper, Northamptonshire Regiment, only son of Dr. H. S. Cooper, of Yaxley, Peterborough.

Capt. J. B. Ford, Royal West Kent Regiment, only child of Surgeon-General Sir R. W. Ford, D.S.O.

Lieut. F. E. S. Townsend, Durham Light Infantry, eldest son of Dr. F. E. Townsend, of Normanby, Yorks.

Lieut. A. E. Townsend, Durham Light Infantry and Royal Flying Corps, second and last surviving son of Dr. F. E. Townsend, of Normanby, Yorks.

Capt. N. West, M.C., Bedford Regiment, second son of Capt. C. J. West, R.A.M.C., of Newbury, Berks.

### MENTIONED FOR WAR SERVICES.

The Secretary of State for War has issued a long list of names which have been brought to his notice for valuable services rendered in connexion with the war, and the names of the following medical officers are included:—

#### Army Medical Service.

Adams, Col. G. G.; Beamish, Col. J. M.; Bedford, Surg.-Gen. W. G. A.; C. B., C. M. G.; Birch, Col. de B., C. B., V. D.; Birrell, Surg.-Gen. W. G.; Bond, Hon. Col. G. J.; Bull, Col. W. H. V. D.; Burnside, Col. E. A.; Butt, Col. E.; Coates, Col. W., C. B.; Croly, Col. A. E. J.; Culling, Surg.-Gen. J. C.; Dewar, Col. T. F.; Faunce, Col. C. E.; Forman, Col. R. H.; Giles, Col. P. B. C. ### THE NATIONAL SERVICE DEPARTMENT AND THE ORGANISATION OF THE MEDICAL PROFESSION FOR MILITARY AND CIVILIAN PURPOSES.

The following letter has been sent by the Director-General of National Service to the Central Medical War Committee, the Committee of Reference of the English Royal Colleges, and the Scottish Medical Service Emergency Committee:

National Service Department, St. Ermin's, Westminster, S.W., Feb. 22nd, 1917.

Sir.—The organisation of the medical profession with a view to meeting the needs both of the military and civil population is one with which this department is now concerned. Up to the present the work of providing the Army with qualified medical men has been undertaken by the Central Medical War Committee with the assistance of the Committee of Reference for England and Wales and the Scottish Medical Service Emergency Committee. It is clear, therefore, that in considering what further steps should be taken these bodies should be consulted and their opinions fully considered. Accordingly I have decided to call a conference, comprising three representatives of the Scottish Medical Service Emergency Committee, four from the Central Medical War Committee, and two from the Committee of Reference, over which I have asked Sir Donald MacAlister, the President of the General Medical Council, to preside, and I should be very much obliged if your Committee would be good enough to nominate representatives from amongst their number who would be prepared to attend. Particulars of the time and place at which the conference will be held will be arranged as soon as the names of all the representatives have been received.

The chairman will be furnished with terms of reference, but for your information I may say that the following will be among the subjects upon which it is desired that the conference should express an opinion: (1) Whether the service to be given by members of the profession should be compulsory or voluntary; (2) what arrangements should be made for the collection and distribution of fees or other form of remuneration in cases where doctors leave their own practices or take on the practices of others; (3) what arrangements should be made: (a) centrally and (b) locally for redistribution of medical men; and (4) what should be the relations between any central executive or advisory body representing the profession and this department.

I am, yours faithfully,

A. NEVILLE CHAMBERLAIN, Director-General.

### SCOTTISH MEDICAL SERVICE EMERGENCY COMMITTEE.

At a conference held recently of the Committee and the secretaries of the Local War Committees for Scotland the following resolution was adopted unanimously:

That this Conference of Secretaries of Local War Committees being informed that further substantial calls are likely to be made on the profession is of opinion that these calls can only be met by mobilising the whole profession.

### THE "C" DISINFECTING FLUID.

The Medical Department of the Navy employed at Gallipoli a preparation known as the "C" disinfecting fluid, which under trial has proved so useful in prevention of the decomposition of carcasses that we cannot help wondering why more has not been heard of the invention and why its use has not become more general. The fluid was devised and standardised at the Pathological Laboratory at Cambridge, and the ideals set forth for it may be briefly summarised as follows: The preservation and deodourising of carcasses of animals and the prevention of the deposit of fly eggs, the destruction of fly maggots developed from eggs deposited before the application of the chemical, a fly deterrent, and a general deodoriser. In November of 1915 Fleet-Surgeon D. W. Hewitt, F.R.C.S., was instructed by Sir Arthur May, the Director-General, to investigate for the Medical Department of the Navy the results of the experiments which had been carried out at Cambridge during a period of six months, and the gist of his report showed that the fluid is a very active disinfectant. The bodies of guinea-pigs, rabbits, goats, pigs, and horses had been exposed for various periods under conditions simulating those to be found in the actual zones of battle. They were grouped in three different areas separated by from two to three miles, presumably with the intention of negativing or minimising the influence of the soil, and they had all been exposed to open air, rain, and sunshine for periods varying from a fortnight to six or seven weeks. The fluid, the exact composition of which has not been made public—though it is, of course, known to Professor G. S. Graham-Smith, of the Pathological Laboratory at Cambridge—is a coal-tar preparation costing only 4*d.* a gallon, and as it can be obtained in large quantities it may be used undiluted. This, indeed, is one of its notable advantages, as no skill is required for making dilutions. Two gallons suffice for treating a horse, and Fleet-Surgeon Hewitt suggests that probably one gallon poured over the clothing of a dead man would be ample to arrest putrefaction.

The Medical Department of the Navy employed at Gallipoli a preparation known as the "C" disinfecting fluid, which under trial has proved so useful in prevention of the decomposition of carcasses that we cannot help wondering why more has not been heard of the invention and why its use has not become more general. The fluid was devised and standardised at the Pathological Laboratory at Cambridge, and the ideals set forth for it may be briefly summarised as follows: The preservation and deodourising of carcasses of animals and the prevention of the deposit of fly eggs, the destruction of fly maggots developed from eggs deposited before the application of the chemical, a fly deterrent, and a general deodoriser. In November of 1915 Fleet-Surgeon D. W. Hewitt, F.R.C.S., was instructed by Sir Arthur May, the Director-General, to investigate for the Medical Department of the Navy the results of the experiments which had been carried out at Cambridge during a period of six months, and the gist of his report showed that the fluid is a very active disinfectant. The bodies of guinea-pigs, rabbits, goats, pigs, and horses had been exposed for various periods under conditions simulating those to be found in the actual zones of battle. They were grouped in three different areas separated by from two to three miles, presumably with the intention of negativing or minimising the influence of the soil, and they had all been exposed to open air, rain, and sunshine for periods varying from a fortnight to six or seven weeks. The fluid, the exact composition of which has not been made public—though it is, of course, known to Professor G. S. Graham-Smith, of the Pathological Laboratory at Cambridge—is a coal-tar preparation costing only 4*d.* a gallon, and as it can be obtained in large quantities it may be used undiluted. This, indeed, is one of its notable advantages, as no skill is required for making dilutions. Two gallons suffice for treating a horse, and Fleet-Surgeon Hewitt suggests that probably one gallon poured over the clothing of a dead man would be ample to arrest putrefaction.

The methods of treatment of the various carcasses employed for experiment were described by Fleet-Surgeon Hewitt as threefold: the fluid can be brushed over the surface of the dead animal, or it can be injected into the carotid artery, or it can be introduced into openings made in the peritoneal and pleural cavities. Carcasses of different bulk were treated by each method, and were found to be deodorised, while putrefaction was greatly retarded or prevented and fly maggots were killed. The most effective technique was found to be the brushing over the surface of the carcass with the fluid, coupled with its injection into the carotid artery. The body of a horse treated in this way was perfectly fresh and odourless a fortnight later. Trenches and latrines when sprayed with the fluid were kept free from flies, which it kills as well as the maggots, and it prevents the ova from being deposited.

*Professor Graham-Smith's Description.*

The following is the routine as described by Professor Graham-Smith for the effective treatment of the carcass of a horse. The carcass should be injected through the carotid artery, using a pump delivering a quantity of "C" fluid from a container—the container used in the Cambridge experiments was the Excelsior 5970 (Benton and Stone, Limited, Birmingham). Two gallons of the fluid will be found sufficient for a horse weighing 1000 lb. The operation takes from 5 to 10 minutes. A further one gallon should be sprayed on the surface with a watering-can. The surface includes legs and feet, and both sides of the animal should be brushed in the direction of the hair which thoroughly distributes the fluid. More fluid should be poured in the ears, eyes, nostrils, mouth, anus, and any wounds. Patches of blood in the neighbourhood should be sprinkled. If the horse cannot be injected the abdomen should be opened in such a manner that the intestines do not fall out, and the intestines should be slashed so as to let out the gas. Then one gallon of the fluid should be poured in and more fluid should be poured into the pleural cavity through an opening between the ribs. Externally the treatment is the same as when the horse is injected, and a similar routine should be followed in dealing with a carcass already putrid, but if it is so offensive as to be unapproachable it can be sprayed at first from a distance. Treated in this way bodies will remain for days without any marked smell, and can be buried when time or opportunity permits. It is recommended that carcasses which are to be buried immediately should also be sprayed and the natural openings and any wounds also be injected, so as to prevent flies hatching out from the eggs which have been deposited.

Against flies, those ubiquitous disease-carriers in all warm zones, the "C" disinfecting fluid acts efficiently. Professor Graham-Smith says that treatment with the fluid will kill all maggots and will prevent flies from laying their eggs for some days, while even if the eggs are laid the maggots will not hatch out.

Flies can be prevented from entering a shelter, such as a dug-out, even if attractive baits are placed inside, by hanging a cloth sprayed with the solution over the entrance. Moreover, it has been found that the smells from putrefying carcasses or faeces are almost completely removed by the use of the fluid. The suggestion follows that probably flies could be kept from the trenches by spraying of the "C" fluid and from men's faces by anointing their caps. Professor Graham-Smith adds that at Cambridge there has not been any opportunity of carrying out experiments on fly-infested rooms, kitchens, and outhouses, but it can be assumed that by treating the floors, doors, and windows with "C" fluid most of the insects could be kept away from such premises and from horse-lines and latrines. The solution can be supplied at 4½d. per gallon in 40-gallon barrels or in 5 to 100-gallon drums, and Mr. F. W. Foreman, F.I.C., of the Cambridge Agricultural Department, who has been associated with Professor Graham-Smith in the work, says that 10,000 gallons could be supplied in a short time, and that the correct material will be supplied in response to orders sent through him. Mr. Foreman adds the following word of caution to men who are constantly using the solution. They should anoint their hands and arms with vaseline and should remember that contact with the fluid causes considerable local irritation to the mouth and eyes.

*A Trial at the Dardanelles.*

As the results of a trial of "C" fluid by a Royal Naval Division at the Dardanelles, Fleet-Surgeon Hewitt made a

further report in which he pointed out that the specific gravity of "C" fluid caused difficulty in obtaining a spray which would throw satisfactorily for more than 20 or 30 yards. Spraying is, of course, not necessary when opportunity occurs for the more effective methods of brushing with the fluid or injection of the fluid into the body, but in the near neighbourhood of trenches corpses of men and animals, and other putrefying material, may lie for some days before any opportunity of other treatment than spraying can be found.

The report from the Dardanelles was made by Staff-Surgeon E. L. Atkinson, and forwarded with a confirmatory report by Fleet-Surgeon Arthur Gaskell.

The following extracts from Staff-Surgeon Atkinson's report will show the scope of the inquiry made:

The body of a Turk killed eight days previously and buried three days in the parapet of a trench was exhumed. Decomposition was in full progress, the stench was terrible, and the carcass was covered with flies, which were breeding in it. The body was lying on its side, and was regarded as a typical case upon which to try the effect of the liquid. About one gallon of the liquid was squirted from a garden spray over the clothes and exposed parts on Oct. 9th, 1915. Some of the flies that were on the body were killed immediately, and the remainder repelled. The stench abated almost immediately. The corpse was left exposed as it was, and there had been a heavy thunderstorm on the previous night. It was not possible to turn it in the daytime because of sniping. On the 11th there was complete absence of smell, only a few flies settled on it for a short time. A further half-gallon was sprayed over it and again on the 12th; there was no smell or flies. The size of the body had markedly shrunken and the result was extremely satisfactory. Again, three or four bodies immediately behind the firing-line were sprayed from a short distance with the fluid. The men had been dead for some time and the smell in the trench from the bodies was very offensive. The smell was damped down entirely by the fluid.

"In trench warfare," says Staff-Surgeon Atkinson, "the use of this substance ought to be invaluable. So many dead are lying within reach of a strong spray from the trench, and these cannot be buried because they are between the enemy and ourselves. It will also certainly repel fly and their breeding in these bodies; also the effect seems to last over an appreciable time." He mentions the need for a forcible pump so as to project a long spray, and notes also the satisfactory use that can be made of the fluid in the deodorising of manure-heaps and latrines.

He summarises his investigations as follows:—1. The fluid is an excellent deodorant. 2. Its effect on decomposition lasts some time—in one very advanced case seven days under observation. 3. It kills flies by spraying them in clusters, and in sufficient quantity repels them for some days from settling on the place sprayed. 4. In dealing with manure spreading in layers and spraying daily would probably be useful.

Fleet-Surgeon Gaskell supplies notes on the trials of the fluid undertaken at the Dardanelles which support Staff-Surgeon Atkinson's conclusions, and adds a note of warning in respect of its extreme inflammability.

**THE ARTIST AT THE FRONT.**

The third instalment of drawings by Mr. Muirhead Bone, issued from the office of *Country Life*, under the title *The Western Front*, by Messrs. George Newnes, Ltd., contains several striking illustrations made in British munition works. Three drawings, entitled "The Gun-pit," show the hardening of the steel, a gun jacket entering the oil-tank, and the great crane which lifts the guns about from furnace to tank and from tank to lathe. They form a fitting introduction to a picture of a vast shell store entitled "The Hall of the Million Shells," and to another reproduced on the frontispiece, entitled "Mounting a Great Gun," wherein the horror of these enormous instruments of death is lost, unless it is accentuated by the serenity of their appearance, which comes of their perfect strength and symmetry.

Other notable drawings in this instalment, notable mainly because they enable us to realise what is really going on at the front, are "A Line of Tanks," "A Kitchen in the Field," a disembarkation scene, and "Thawing Out," which records in a lively manner the bitter cold to which the aviator has to submit. In the first plate, an illustration of the market square at Caesel, Mr. Muirhead Bone is at his best as a chronicler of the graces and spaces of an ancient city.

## Obituary.

**THOMAS SEYMOUR TUKE, M.A., M.B., B.CH. OXON.,  
LECTURER ON MENTAL DISEASES AT ST. GEORGE'S HOSPITAL, LONDON.**

We much regret to announce the death, in his sixty-second year, of Dr. T. S. Tuke, who has fallen a victim to pneumonia following rapidly upon an apparently simple cold.

Thomas Seymour Tuke was the son of Dr. Harrington Tuke, who in the last generation was a leading consultant physician for mental disorders, and he was the grandson of the famous Dr. John Conolly, associated in this country with the abolition of mechanical restraint in the treatment of the insane. Young Tuke was educated at St. Paul's School and, winning a scholarship, proceeded to Brasenose College, Oxford, and later to St. George's Hospital. At school and college he developed the love of sport which remained with him throughout his life. He became a useful cricketer and a fine horseman as well as a good shot, and at St. George's Hospital he made a leisurely passage through his examinations and added to the already large number of personal friends which his kindness of heart, charm of manner, and love of games had acquired for him at school and college. It was not until after Tuke graduated in medicine at Oxford that he showed his real quality as a physician. Bred from his earliest years in association with the most humane treatment of mental sufferers, he rapidly developed into a skilful adviser. On the practical side of treatment he was especially helpful, and he had strong views as to the necessity of long training by residence with the insane for those who would dictate their treatment. He frequently insisted on the dangers which might follow on the existing fashion of placing insane patients in ordinary nursing homes or with inexperienced guardians, and he spoke from the full knowledge of his subject gained as co-licensee with his brother, Dr. Charles M. Tuke, of Chiswick House. Appointed lecturer on mental diseases at St. George's Hospital, his instruction to the students was always of a practical character; and, as a matter of fact, he conducted no original researches, but his general advice on matters connected with lunacy to those of the students who intended to become general practitioners was exactly what they required.

By the death of Dr. Tuke there is removed from among us one of the kindest and most sympathetic of men, who discharged his professional duties with the highest appreciation of their importance and delicacy. He married a daughter of the late Dr. Graily Hewitt, the well-known obstetric physician, in 1890, and his wife and daughter survive him. In THE LANCET of May 22nd, 1915, we announced the death in the war of his only son, Second Lieutenant A. H. S. Tuke.

## Medical News.

**WEST LONDON MEDICO-CHIRURGICAL SOCIETY.**—At a meeting to-day (Friday, March 2nd), in the society's rooms at the West London Hospital, a paper will be read by Mr. Aslett Baldwin on "Some Mistakes in Diagnosis."

**ROYAL MEDICAL BENEVOLENT FUND.**—At the last meeting of the committee, held on Feb. 13th, 20 cases were considered and £162 granted to 15 of the applicants. Four of the applicants were elected to vacant annuities. The committee also decided to increase the number of annuities by 12. The following is a summary of the cases relieved:—

Widow, aged 40, of F.R.C.S. Eng. who practised in Rotherhithe and died in 1913. Applicant was left without means and decided to endeavour to earn a living by taking paying guests, and took a house in June 1914, on three years' lease on the Kent coast. The prospects were bright, but the war stopped all visitors, and she has had the house on her hands and had to work as a nurse to pay the rent. The landlord will release her of her responsibility if she pays £10, so she wants the loan of that amount. One son is a foundation scholar at Epsom. Voted £10.—Widow, aged 42, of M.B., C.M. Gasq., who practised at Blackpool and died in 1911. Applicant was left without means with one daughter, aged 8 years. She went to America, and was able to earn a living for a time, but owing to her health breaking down she returned to England. At the present time her health is very bad, and the Glasgow branch of the Guild have provided her with a temporary home and are giving her invalid comforts. The daughter, now 14 years of age, is earning 8s. per week; this is the only income. Voted £12.—M.D. St. And., aged 72, and married. Was a missionary in India,

and afterwards for many years practised in the City of London. Lost his practice through the premises he occupied being required for City improvements, and he was not properly compensated. Has recently had an hemiplegic attack and quite unable to work. Voted £5.—Daughter, aged 43, of L.R.C.P. Eng. who practised at Wymondham and died in 1882. Applicant was left entirely without means and went with her mother to France, where they acted as governesses. The mother died, and the applicant, who had never been strong, returned to England and tried to earn a living by teaching French and Spanish, but was not very successful. At the present time is in great poverty, and health very bad. Relieved twice, £7, in 1911. Voted £7.—Daughter, aged 57, of M.R.C.S. Eng. who practised at Rotherhithe and died in 1879. Applicant suffers from chronic glaucoma, and before this earned a living as a nurse. Only income £24 from friends, and small investment. Relieved eight times, £79. Voted £12 in 12 instalments.—Widow, aged 70, of M.D. St. And. who practised at Kidderminster and died in 1884. Applicant was left with less than £50 per annum, and tries to supplement this by taking in lodgers, but owing to ill-health and age cannot continue to do this. Relieved twice, £22. Voted £12 in 12 instalments.—Widow, aged 69, of M.R.C.S. Eng. who practised in London and died in 1893. Applicant is a cripple, and only able to earn very little as an artist. She owns a house which is let, but owing to its being in such a bad state of repair practically all the rent goes in repairs. Relieved twice, £22. Voted £12 in 12 instalments.—Daughter, aged 60, of M.R.C.S. Eng. who practised at Box, Wilts, and died in 1894. Has two sisters who are invalids partly dependent on her. Only able to earn about 2s. a month as a companion. One of her sisters is helped by the Fund and the Guild. Relieved eight times with sister, £126, and self three times, £48. Voted £18 in 12 instalments.—Daughter, aged 43, of M.R.C.S. Eng., who practised at Scarborough and died in 1879. Was left without means, and owing to ill-health not able to earn sufficient by nursing to pay her way. Relieved 12 times, £117. Voted £10 in two instalments.—Daughter, aged 55, of F.R.C.S. Eng. who practised at Bedford and died in 1890. Applicant, whose health is very indifferent, earns a little in domestic service, but health will not permit her continuing in one place long. Has recently poisoned her thumb and is in great distress. At the request of the Guild visitor an emergency grant of £2 has been sent to her. Relieved 11 times, £28. Voted £12 in four instalments.—Widow, aged 60, of M.R.C.S. Eng. who practised at Hexham and London, and died in 1908. Was left entirely without means and endeavour to earn a living by taking in lodgers. Has one daughter, a teacher, who earns 2s. per week, and this is the only certain source of income. Relieved seven times, £84. Voted £12 in 12 instalments.—Wife, aged 50, of M.R.C.S. Eng., a Major in the R.A.M.C. She was deserted by her husband nine years ago and left with a delicate daughter now 29 years of age. Through the illness of her daughter, and the fact that her husband's allowance was stopped for 18 months, she has got into temporary financial difficulties, and owes for her removal expenses to her present home and for other items. Her prospects are good if she can obtain help now. Relieved twice, £20, in 1913. Voted £50 from Fund and Guild.—Daughter, aged 52, of M.R.C.S. Eng. who practised at St. Clears and died in 1878. Applicant suffers from double spinal curvature. Her mother is an annuitant of the Fund. Relieved three times, £18. Voted £6 in 12 instalments.—M.R.C.S. Eng., aged 49, who practised mainly in West Africa. He is totally incapacitated from work due to stroke and other trouble. Lives with an aunt whose means are very limited. A relative allows £24 a year. Relieved three times, £25, last £5 in June, 1916, with permission to apply again in six months. Voted £5.—Daughter, aged 69, of M.R.C.S. Eng. who practised at Battle, Sussex, and died in 1873. Lives with sister, who can only help her a little. Suffers from rheumatism and bad sight. Relieved 33 times, £226. Voted £12 in 12 instalments.—Widow, aged 48, of M.R.C.S. Eng. who practised at Deal and died in 1904. Only income £20 from dividends. Shares home with mother and sister whose means are limited. Unable to meet expenses owing to the high cost of food. Voted £10 in two instalments.

Subscriptions may be sent to the honorary treasurer, Dr. Samuel West, at 11, Chandos-street, Cavendish-square, London, W.

## Parliamentary Intelligence.

### NOTES ON CURRENT TOPICS.

#### Legislation on Venereal Diseases.

It is anticipated that a Bill dealing with certain matters in relation to venereal diseases will be introduced in the House of Commons at no distant date on behalf of the Local Government Board. The Criminal Law Amendment Bill, which is under the care of the Home Secretary, contains a clause imposing penalties on persons who knowingly communicate venereal disease to others. It was read a second time last week and was formally referred to "a Committee of the whole House." A suggestion was made that this decision should be rescinded and that the measure, along with the promised Bill of the Local Government Board, should be dealt with by a Grand Committee—that is, a committee on which selected Members of the House sit. The idea is that this course would secure continuity of outlook in dealing with the details of both measures. The Government has given its assent to this suggestion, and, so far as the Criminal Law Amendment Bill is concerned, a resolution has been passed which will have the effect of sending it to a Grand Committee for detailed consideration.

#### Use of Cocaine in Dentistry.

The Committee which has been considering questions with regard to the use of cocaine in dentistry, particularly by unregistered practitioners, has made its report to the Home

Secretary. Sir GEORGE CAVE has laid it on the table of the House of Commons. He intimates that the report raises some questions which will require consideration. He proposes for that reason to extend for two months the permit to unregistered practitioners in dentistry to use solutions containing not more than 1 per cent. of cocaine.

## HOUSE OF COMMONS.

WEDNESDAY, FEB. 21ST.

## Medical Notes of Wounded Men.

Mr. SNOWDEN asked the Under Secretary for War what medical notes had been, or were now, sent with wounded men from Flanders; and whether arrangements would be made to permit a wounded man being accompanied by medical notes on his own case, and the details of treatment carried out, so as to avoid delay and unnecessary manipulation on his arrival in England.—Mr. MACPHERSON answered: Each man has attached to his coat a card giving particulars of the case. Improvements of this card are now being carried out and a fuller history of the case will be given.

THURSDAY, FEB. 22ND.

## "Manipulative" Surgery.

Mr. MACVEAGH asked the Under Secretary for War whether the Army Medical Department was aware that the Medical Act of 1858 applied only to persons falsely styling themselves physicians, doctors of medicine or surgery, or surgeons; whether the department was also aware that experts in manipulative treatment did not come within any of those descriptions, did not so style themselves, and had never asked to be so employed; and whether he could state what section of the Act could, under those circumstances, be construed as preventing the department from using the services of these experts.—Mr. MACPHERSON wrote in reply: No, sir, I am not aware that my honourable friend's interpretation of the Medical Act is correct. I think if he refers to the Act he will find that it prohibits the appointment of any person as a medical officer unless he is registered. Every branch of medicine and surgery pursued by lawfully qualified medical men is represented amongst those employed by us.

Mr. MACVEAGH asked whether the Army Medical Department was yet in a position to say whether the British Medical Committee (Balneological Section) had reported on the use of manipulative treatment in France; and whether the Army Medical Department in this country proposed also to make use of every possible aid for wounded soldiers.—Mr. MACPHERSON replied: Yes, sir. They have reported on certain methods of treatment, all of which are in use in this country.

Answering further questions, Mr. MACPHERSON wrote: Any professional degree recognised by the law of the land is recognised by the Army Medical Service. The so-called manipulative treatment is in full swing in the Army under well-known authorities on the subject. My honourable friends who take an interest in the subject of manipulative treatment may rest assured that facilities for discussion will be afforded at an early date on the introduction of the Army Estimates.

## Epileptics amongst Discharged Soldiers.

Answering Mr. KING, who asked a question bearing on the treatment of epileptics discharged from the Army, Sir A. GRIFFITH-BOSCAWEN (representing the Ministry of Pensions) wrote: The Minister of Pensions has no precise information as to the number of persons who have become epileptics subsequent to enlistment, but I am advised that it is not large. The treatment and training of epileptics is, however, being carefully considered. A scheme has been approved by the Statutory Committee for additions to the accommodation at Chalfont Colony, and a special joint committee on institutional treatment, who have secured the services of an expert medical man, are considering the further steps to be taken.

WEDNESDAY, FEB. 28TH.

## Venereal Disease in the Army.

Answering Mr. KING, who asked for figures of cases of venereal diseases in the Army, Mr. MACPHERSON (Under Secretary for War) wrote: The present admission ratio for troops in the United Kingdom is 43·5 per 1000 per annum. This figure is a reduction on that furnished on Nov. 16th. In France the proportion is 24 per 1000.

The following journals, magazines, &c., have been received:—Journal of Anatomy, Maryland Medical Journal, Archives of Radiology and Electrotherapeutics, Surgery, Gynecology, and Obstetrics, American Journal of Syphilis, American Journal of Roentgenology, Bulletin of the Johns Hopkins Hospital, Medical Review of Reviews, American Journal of Public Health, Ellingswood's Therapeutist, Medical Times, Clinical Medicine, Pediatrics, Malaria, Psychoanalytic Review, American Journal of Obstetrics, Modern Hospital, American Journal of Medical Sciences, Journal of Mental Science, Military Surgeon, American Journal of Orthopedic Surgery.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

APPLECROSS, PARISH OF, ROSS-SHIRE.—Medical Officer, &c., for Torricon District. Estimated emoluments £350 per annum.

ASHTON-UNDER-LYNE, LANC., DISTRICT INFIRMARY AND CHILDREN'S HOSPITAL.—Assistant House Surgeon. Salary £160 per annum, with usual emoluments.

BEDFORD COUNTY HOSPITAL.—House Physician, unmarried. Salary £150 per annum, with board, &c.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Female House Surgeon. Salary £200 per annum.

BIRMINGHAM CITY.—Assistant Tuberculosis Officer for West Heath Hospital and Assist at Anti-Tuberculosis Centre, Broad-street. Salary £350 per annum, with board, &c.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Female House Surgeon. Salary £150 per annum, with board, &c.

BRISTOL ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.

BURNLEY, VICTORIA HOSPITAL.—House Surgeon. Salary £160 per annum, with board, &c.

BURY INFIRMARY.—Junior House Surgeon. Salary £150 per annum, with board, &c.

CAMBRIDGE, COUNTY MENTAL HOSPITAL.—First Assistant Medical Officer. Also Junior (Second) Assistant Medical Officer, unmarried. Salaries £300 and £220 respectively, with board, &c.

DUNDEE DISTRICT ASYLUM.—Assistant Resident Medical Officer. Salary £300 per annum, with board, &c.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £200 per annum, with board, &c.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Assistant Casualty Medical Officer. Salary at rate of £60 per annum, with board, &c.

LONDON COUNTY COUNCIL.—Two Female Medical Inspectors (unmarried or widows) in the Public Health Department. Salary £300 a year.

MANCHESTER, ABERGLEN SANATORIUM.—Temporary Medical Superintendent. Salary £300 per annum, &c.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road.—House Surgeon. Salary £120 per annum, with board, &c.

NEWCASTLE UPON-TYNE EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary £300 per annum.

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford.—House Surgeon.

SALFORD ROYAL HOSPITAL.—Junior House Surgeon. Salary at rate £150 per annum, with board, &c.

SOUTHAMPTON PARISH INFIRMARY, Shirley Warren.—Resident Assistant Medical Officer. Salary £250 per annum, with apartments, &c.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician and Junior House Surgeon. Salaries £150 and £120 per annum respectively, with board, &c.

SUNDERLAND ROYAL INFIRMARY.—Female House Surgeons. Salaries—Senior, £260; Junior, £200 per annum, with board, &c.

WEST HAM UNION SICK HOME, 86, Forest-lane, Forest Gate, E.—Resident Assistant Medical Officer. Salary £300 per annum, &c.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL.—Resident Medical Officer. Salary as arranged, with board, &c.

## Births, Marriages, and Deaths.

## BIRTHS.

ASH.—On Feb. 21st, at The Lodge, Brampton grove, Hendon, to the wife of Dr. Edwin Ash (of Harley-street, W.)—a son.

KENNEDY.—On Feb. 18th, in London, the wife of Captain Charles M. Kennedy, R.A.M.C., of a son.

MURRAY.—On Feb. 25th, at 95, Cadogan-gardens, W., the wife of W. Murray, M.B., D.P.H., of a son.

## MARRIAGES.

LAMBERT—LOCKHART.—On Feb. 22nd, at St. Martin's by Looe, Cornwall, by the Rev. W. S. Picken, M.A., Surgeon John Lambert, M.D., R.N., eldest son of the late John Lambert, of Cambridge, to Alice Margaret, fifth daughter of the late James Lockhart, The Elms, Kirkcaldy.

MAYBERRY—HESLOP.—On Feb. 20th, at St. Mary's Church, St. Ives, Cornwall, George Mahony Mayberry, Temporary Captain, R.A.M.C., to Lily, eldest daughter of the late William Heslop.

## DEATHS.

FORSTER.—On Feb. 11th, of heart failure following influenza, while in charge of a hospital at Zaleszczyki, Galicia, Dr. Laura Forster.

MCKELLAR.—On Feb. 20th, at 10, Crondace-road, Fulham, Peter Hugh Montgomery McKellar, M.A., M.B., O.M. Glasg., aged 72.

TUKE.—On Feb. 23rd, at Chiswick House, Chiswick, W., from pneumonia after a short illness, Thomas Seymour Tuke, M.A., M.B.Oxon., aged 61.

WEBER.—On Nov. 20th, at Georgetown, British Guiana, Hubert Clinton Weber, M.D. Edin., aged 34.

WILLIAMSON.—On Feb. 21st, at Durley, Camberley, Deputy Surgeon-General Benjamin Williamson, I.M.S., retired, aged 83 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

### PUBLIC HEALTH IN BRITISH GUIANA.

A REPORT prepared by Mr. E. W. Ball Greene, Acting Assistant Secretary, on the affairs of British Guiana for the year 1915, has been presented to Parliament. From it we gather that the Registrar-General's estimate of the population of the colony on Dec. 31st, 1915, was 312,391 (162,403 males and 149,988 females). The general birth-rate for 1915 was 31·3 per 1000 of the estimated population, that of each of the several races representing the community being as follows: Portuguese, 20·5; Europeans other than Portuguese, 12·9; East Indians, 32·6; Chinese, 30·6; Blacks, 29·5; Mixed Races, 33·9. Of the births registered 44·5 percent were legitimate and 55·5 percent illegitimate. The general death-rate was 27·7 per 1000, that of the various races being: Portuguese, 28·0; Europeans other than Portuguese, 11·6; East Indians, 28·8; Chinese, 25·9; Blacks, 28·4; Mixed Races, 20·5. The six principal causes of death throughout the colony during the past five years are given as follows: Bowel complaints (including dysentery, diarrhoea, and enteritis), 15·4 per cent. of the general mortality; fevers (malaria and others), 14·6; pneumonia and bronchitis, 11·4; kidney diseases, 8·8; diseases of early infancy (including premature birth, infantile debility, &c.), 8·0; and phthisis and other forms of tuberculosis, 5·7 per cent. Enteric fever is a notifiable disease; during 1915, 419 cases were notified with 75 deaths. Anti-malaria and anti-mosquito measures are being generally and gradually enforced with visible signs of success. The number of screened vats in the city of Georgetown has increased as a result of the screening regulations being enforced. In 1906-7 33,748 cases of malarial fever were treated in the sugar estates' hospitals; in 1915 the numbers had fallen to 11,788. Quinine has been for some years sold at all post-offices to the general public at cost price. It is also distributed by the sugar estates free to their labourers, and by the Government to prisoners, members of the police force, and inmates and attendants at the public institutions. Ankylostomiasis, which has engaged the attention of the medical department for several years, has considerably decreased on the sugar estates; this is attributed to improved sanitary measures and the erection of latrines.

There are five public hospitals in the principal centres of population, and the outlying districts are served by dispensary hospitals and dispensaries. The immigration law also requires the maintenance of hospitals on every plantation on which there are indentured East Indian labourers, and these institutions are available for the treatment of emergency and pauper cases from the general community. There were 434 patients in the public hospitals at the beginning of the year and 11,304 were admitted during the year; there were 1399 deaths. In addition to those admitted to hospital, out-door treatment was given to 37,574 persons. The daily average of inmates in the lunatic asylum was 775; 75 were discharged cured during the year and 74 died. At the leper asylum there were 381 patients when the year began (265 males and 116 females) and during the year 44 were admitted.

### POTATOES.

THERE have been several references lately in the newspapers to forcing the growth of potatoes, and the suggestion has been made of placing the seed potatoes in shallow boxes in a warm place before planting out. This suggestion, though apparently novel, is at least 20 years old, as the Rhode Island Agricultural Station in the United States then published a bulletin giving the results of experiments made by planting potatoes in pots in a greenhouse and transplanting them out of doors. Another method was to expose small potatoes as large as hen's eggs to heat and light for six weeks, to develop a strong bud and roots before planting them. Both plans gave a better yield, especially the last, which resulted in a gain of 32 bushels per acre. The acreage under potatoes in the United States has steadily grown. The figures nine years ago had reached 3,257,000 acres, producing 278,935,000 bushels, or an average of 85·7 bushels per acre, with a farm value of 197,039,000 dollars; an average price of cents 70·6 per bushel. 52 bushels equal 189 dekalitres. The main crop goes under the name of "Irish potatoes," but there is also a crop of 60 million bushels of "sweet potatoes." This is the esculent root of the *Ipomoea batatas*, or *Batatas edulis* or *Convolvulus batatas* much eaten in the United States. In Peru it is called *camote*; in Cuba *boniato*; in Spain *batata de Malaga*; in other countries Spanish or Indian potatoes. It is the spindle-shaped tuber of a species of convolvulus, and is said to have been used for food

before the common potato was eaten. It contains 16 per cent. of starch and 10 per cent. of sugar. This is the "potato" referred to by early writers, and Shakespeare in *Troilus and Cressida* refers to the "potato finger," meaning a long thick finger. Sweet potatoes require a warm climate. In England they were introduced from Spain and the Canaries, but potato-growing was not encouraged in England in the Stuart times, and even so late as early Victorian days some political economists thought the "potato rot" might be a blessing if it taught the working classes not to rely upon potatoes but to seek better food. In contrast to this our Royal Society in 1663 took some measures for encouraging the cultivation of potatoes with the view of prevention of famine.

### VITAL STATISTICS OF BERMUDA.

Lieutenant-General Sir G. M. Bullock, K.C.B., Governor of Bermuda, has forwarded to the Colonial Office a report on the Blue book for 1915, from which it appears that at the end of the year the estimated total civilian population was 20,801, composed of 7219 whites and 13,582 coloured. The birth-rate for the year was 22·16 per 1000 among white residents and 35·59 among coloured residents. The death-rate was 13·85 per 1000 among white resident civilians and 18·18 among the coloured. The mortality among children under 5 years of age was 31·2 per cent. (10·27 whites and 39·67 coloured) of the total deaths. The deaths from cancer numbered 18 and those due to tuberculosis 33. No outbreak of serious infectious disease occurred during the year. The mean temperature of the air for the year was 69·8° F. and the total rainfall 61·8 inches. There is no hospital maintained by the Colonial Government, but the King Edward VII. Memorial Hospital is expected to be ready for occupation early in 1917. There is a cottage hospital near the city of Hamilton which is supported by voluntary contributions, and hospitals are also maintained in connexion with the Imperial naval and military establishments. The number of visitors to the colony in 1915 was only 10,831, as compared with 14,773 in 1914 and 21,595 in 1913, the decrease being attributed to the dislocation of the steamship service with New York owing to the war.

## Medical Diary for the ensuing Week.

### SOCIETIES.

#### ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Papers:—Mr. W. B. Bottomley: Some Effects of Growth-promoting Substances (Auximones) on the Growth of Lemma minor in Culture Solutions (communicated by Prof. F. W. Oliver).—Florence A. Mockeridge: Some Effects of Growth-promoting Substances (Auximones) on the Soil Organisms concerned in the Nitrogen Cycle (communicated by Prof. F. W. Oliver).

#### ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W. MEETINGS OF SECTIONS.

Thursday, March 8th.

#### BALNEOLOGY AND CLIMATOLOGY (Hon. Secretaries—Chas. W. Buckley, J. Campbell McClure): at 5.30 P.M.

Demonstration  
Of Mensuration Apparatus in use at the Red Cross Clinic for the Physical Treatment of Officers, 126, Great Portland-street, W. (with cases).

Paper:  
Mr. J. Roldie: Manipulation Bath. (Communicated by Dr. J. Campbell McClure.)

#### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Hunterian Lecture:—Major A. B. Webb-Johnson, R.A.M.C.: The Surgical Complications of Typhoid and Paratyphoid Fevers.

#### ROYAL COLLEGE OF PHYSICIANS, EDINBURGH, Hall of the College, Nine Quay-en-street.

MONDAY.—5 P.M., Morison Lectures:—Dr. E. Bramwell: Neurology of the War—Gunshot Wounds of the Peripheral Nerves. (Lecture I.)

FRIDAY.—5 P.M., Morison Lectures:—Dr. E. Bramwell: Neurology of the War—Shell Shock and the Effects of Head Injuries. (Lecture II.)

#### POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Parrot: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

**FRIDAY.**—10 A.M., Dr. Simson: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

**SATURDAY.**—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE,** Prince of Wales's General Hospital, Tottenham, N.

**MONDAY.**—Clinics:—10.30 A.M., Surgical Out-patients (Mr. H. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham); Gynaecological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leesle).

**TUESDAY.**—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).

**WEDNESDAY.**—Clinics:—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. E. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. F. Brooks).

**THURSDAY.**—2.30 P.M., Gynaecological Operations (Dr. A. B. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leesle).

**FRIDAY.**—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. H. Gillespie); Eye Out-patients (Mr. E. P. Brooks).

**THE THROAT HOSPITAL,** Golden-square, W.

**MONDAY.**—5.15 P.M., Special Demonstration of Selected Cases.

**THURSDAY.**—5.15 P.M., Clinical Lecture.

**ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN,** 49, Leicester-square, W.C.

**TUESDAY**—6 P.M., Dr. K. Stille: Ionisation. Electrolysis.

**WEDNESDAY**—5 P.M., Dr. W. Griffith: The Pathology of Diseases of the Skin.

**ROYAL INSTITUTE OF PUBLIC HEALTH,** Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

**WEDNESDAY.**—4 P.M., Lecture VIII.:—Prof. F. G. Hopkins: The Selection and Preparation of Foods in War Time. Prof. D. N. Paton, Prof. W. H. Thompson, Dr. M. S. Pembrey, Dr. A. W. J. MacFadieen, and Dr. W. J. Howarth have promised to take part in the discussion.

**ROYAL INSTITUTION OF GREAT BRITAIN,** Albemarle-street, Piccadilly, W.

**MONDAY.**—5 P.M., General Meeting.

**THURSDAY.**—3 P.M., Prof. A. Denny: Sponges: a Study in Evolutionary Biology. (Lecture I.)

**FRIDAY.**—5.30 P.M., Sir Almroth Wright, C.B.: The Treatment of Wounds in War.

#### METEOROLOGICAL READINGS. (Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Feb. 28th, 1917.

Date.	Rain-fall.	Solar Radio in Vesno.	Maxi- mum Temp. Shade.	Min. Temp.	Wet Bulb.	Dry Bulb.	Remarks.

" 26	0.01	73	49	36	37	38	Fine
" 27	...	64	49	36	37	37	Overcast
" 28	...	60	47	37	39	42	Overcast

Other information which we have been accustomed to give in these "Readings" is withheld for the period of the war.

#### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Office: 423, STRAND, LONDON, W.C.

#### MANAGER'S NOTICES.

##### VOLUMES AND CASES.

VOLUMES for the second half of the year 1916 are now ready. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half-year's numbers (inland edition) are also ready. Cloth, gilt lettered, price 2s., by post 2s. 4d. To be obtained on application to the Manager, accompanied by remittance.

##### ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8d. The rates of subscription remain as revised in October.

##### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

##### TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 6.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

Hunterian Lectures

ON THE

INDIAN OPERATION OF COUCHING  
FOR CATARACT.

Delivered before the Royal College of Surgeons of England  
on Feb. 19th and 21st, 1917,

By R. H. ELLIOT, M.D. LOND., F.R.C.S. ENG.,  
LIEUTENANT-COLONEL, INDIAN MEDICAL SERVICE.

(Concluded from p. 330.)

THE CHAMBERS OF THE EYE.

The Anterior Chamber.

THIS chamber showed departures from the normal in different directions. These will be dealt with under separate headings.

1. Scantiness of contents.—One chamber was quite empty, due to the presence of a corneal fistula. (*Vide Fig. 14.*) In a number of cases the chamber was greatly shallowed, owing to the encroachment of the vitreous body upon it. In these the filtering angle was sealed by adhesion over a wide area. In a few cases *l'iris bombe* was responsible for the shallowing of the chamber. (*Fig. 22.*) In yet others a severe plastic inflammation had involved the structures, lying in and posterior to the aqueous chamber, and had matted them to the posterior surface of the cornea, thus almost obliterating the cavity. This union had been so strong that in the process of hardening the membrane of Descemet remained adherent to the organised exudate beneath it, and a spurious chamber was thus formed lying in the substance of the cornea.

2. Hypopyon was present in 6 specimens, and in 1 the pus was mixed with blood. The length of histories in these cases varied from a matter of months up to 20 years.

3. Hyphema—Blood was present in the anterior chamber in 9 specimens. In some of them it was fresh, whilst in others it was altered and decolourised. The long histories given by a number of these cases suggest either that there had been some recent cause for hemorrhage, or else that a leakage of blood had been constantly occurring. In 2 of the eyes the iris had been torn; in every one of the others there was evidence that severe iritis had been present.

4. Vitreous in the anterior chamber.—In 4 eyeballs the aqueous and vitreous cavities appear to have been in free communication with each other, and filaments of the vitreous body can be traced into the anterior chamber. In 2 of these the angle was widely open, and in the other 2 it was closed by irido-corneal adhesions.

5. Lens matter in the chamber (*Vide Figs. 3, 4, and 5.*).—In four eyes lens matter was found in the anterior chamber. In one the history showed that a nucleus had passed freely backwards and forwards between the two chambers. In another a Morgagnian cataract was wedged in the angle of the chamber, but had contracted no adhesions; in the remaining two the nuclear masses were firmly fixed in position by an abundant quantity of exudate.

6. Albuminous exudates in the anterior chamber.—These were found in three cases; few or no structural elements were present; during life the contents of the chamber were fluid, but they had coagulated under the influence of the formalin preparation of the specimens; they were probably derived from the iris and ciliary body.

The Vitreous Chamber.

In the great majority of the eyeballs under examination it was observed that the vitreous body had become detached and shrunken, and that its remnants showed distinct signs of infiltration and often of organisation. The appearances observed in the various cases fall naturally under a number of headings. 1. Very slight evidence of vitreous structure is discernible. (*Vide Fig. 6.*) 2. Filmy masses are present in the chamber. (*Vide Fig. 7.*) These either (a) are confined to the anterior portion of the chamber, or (b) take the form of a cone with its apex at the nerve head, and its base in the neighbourhood of the ora serrata and ciliary body. 3. Masses are present which give the impression of being freely

NO. 4880.

infiltrated with inflammatory material (*vide Fig. 8*); either throughout their substance or in isolated foci; these may be divided into the same subgroups, (a) and (b), as those under the previous heading. 4. A distinct fibrous organisation is noticeable in the conical masses, which represent the detached and shrunken vitreous. (*Vide Fig. 9.*) 5. No detail is discernible (*vide Fig. 11*) owing to the fact that the retina has become detached and inextricably matted with the one-time vitreous contents, and with the iris and ciliary body.

There are certain preliminary points which we must first settle. 1. There is no essential difference between the cases in which there is a definite cone of filmy or infiltrated membrane reaching from the optic nerve head to the ciliary body, and those in which deposits of a similar nature are found confined to the anterior portion of the vitreous chamber. The grounds for this statement are as follows:

(a) An examination of the more complete specimens of conical exudate shows that the membrane becomes very slender as the nerve head is approached, and it is obvious that very little violence would be required to break this delicate thread across, and so to allow the whole membrane to be gathered up by its own elasticity towards its large and strong anterior attachments. (b) There is strong evidence in a number of the specimens of this series to show that the contraction of the shrinking inflammatory material within the globes takes place with such force as might easily suffice to break across the slender nerve attachment of some of these cones. (c) It is obvious that in not a few cases the tapering apex of a conical exudate is likely to be cut across during section of the globe or broken across during subsequent manipulations. (d) Specimens, in which the exudates presented a definite conical shape, when they were first cut in India, have arrived in this country transformed during the voyage into the similitude of those, in which this exudate is loosely gathered into the fore part of the vitreous chamber; the apex of the cone had been broken off at the nerve head, and the exudate had moved forward by virtue of its own elasticity toward the anterior attachments of the mass. Taking all these points into consideration, we may conclude that in all the eyeballs which present the appearance of shrunken vitreous the structure was originally conical in form and that departures from that shape are merely artefacts. Stress is laid on this point, because in a number of the globes the appearances present suggest that the exudate is poured out from the ciliary body and is confined to the neighbourhood of that structure. We believe such interpretation to be quite erroneous and to be founded on the observation of artefacts.

2. Is this appearance of a shrunken vitreous body definitely pathological? The answer is in the affirmative, for the following reasons: (a) All these globes were treated alike, being dropped into 5 per cent. formalin solution on removal and kept there till frozen and cut. (b) Normal eyeballs treated in this way present no such evidence of definite vitreous structure. (c) Every grade can be traced in the series before us, between the appearance of delicate filmy membranes in the vitreous, and the presence of firmly organised structures. (d) Though it is very difficult to examine these exudates satisfactorily under the microscope, there are a large number of specimens which definitely show evidence of an inflammatory exudation, strengthening and thickening the vitreous body. In not a few of these the anterior hyaloid membrane (the term is used in a non-committal sense) is definitely thickened and infiltrated with inflammatory material. (*Vide Fig. 12.*) The conclusion arrived at is that these widely varying evidences of structural alteration in the vitreous body, are to be interpreted as due to the penetration of the hyaloid by-inflammatory material of chemotoxic origin, and to the subsequent organisation of that infiltration. (e) There still remains the clinical evidence. The lecturer was increasingly reluctant, as his Indian experience accumulated, to remove lenses which had been couched. It was not that vitreous escaped, but that the results of operation were usually poor, and that the blame of the lost sight was then apt to be most unfairly ascribed to the extraction operation. In view of the frequent occurrence of vitreous changes this failure to help the patients is easily explained. Major Kirkpatrick has taken a different, and possibly a more generous, view of the situation, and has removed a number of these couched lenses; his evidence is of extreme interest in the light of our recent pathological findings; he has been "struck by the rarity of vitreous

escape even after a fairly extensive investigation with a "spoon" in extracting a couched lens. He adds:

"I have noticed that the vitreous body becomes shrunken and extraordinarily tough, so much so that when an eye is excised (either for glaucoma or for irido-cyclitis following Mahomedan operation) the whole globe can be held up by a strabismus hook transfixing the vitreous, though the latter appears perfectly clear. The vitreous undoubtedly does undergo shrinkage, and leaves a large space, which is occupied by aqueous."

Straub<sup>1</sup> has described some experiments which he made on animals, in the course of which he injected pathogenic organisms either into the vitreous or into the ciliary body; the result varied according to the part infected, and the poisoned area attracted leucocytes by chemotaxis to itself. Particular interest attaches to the following of his findings: (1) The optic nerve head was swollen and filled up with leucocytes; (2) there was evidence "that the lymph current of the vitreous goes by the optic nerve and that chemotactic substances are brought by this current from the granuloma (the artificial infection) to the nerve"; (3) the leucocytes found in the vitreous showed the way from the granuloma to the cup of the optic nerve—they were seated on thin membranes and most of them were heaped together in small dots; (4) aggregations were found on the walls of the cavities of the eye (on the cornea, on the retina, on the lens capsule, &c.), attracted there, in Straub's opinion, by a chemotactic action.

In the experiments above considered, which were very limited in number, an effort was made to localise the infection to one or other part of the eye and to work with a virus (tubercle bacilli) which was comparatively constant in its toxicity.

What Straub did with a few eyes has been done in the series now before us by the Indian coucher in 54. The interest of the experiments is heightened by the fact that whereas in the Dutch experiments the toxicity of the virus was kept as constant as possible, in the Indian ones it varied from that of organisms which took many years to destroy the sight to that of those which at once produced a fulminating panophthalmitis. One point more—the Indian operator made no effort to confine his procedure (and with that procedure went infection) to any one structure; sometimes he attacked the lens from in front, and in doing so he often primarily injured the iris but may have spared the vitreous chamber; sometimes he entered through the ciliary body or through the choroid, opening up the hyaloid cavity in doing so. His want of skill and the slenderness of his anatomical knowledge made him catholic in the damage he inflicted, but running through his work is the trail of septic infection of the eyeball by penetrating wounds. The result is that he has provided us with a large material of extraordinary interest in the study of the problem which Straub started on.

*The filmy masses in the vitreous chamber.*—As has already been stated, the contents of the vitreous chamber in these specimens vary from thin gauzy films, which can only be detected by careful search, up to thick masses which strike the eye as soon as the specimen is looked at.

It is not easy to obtain a view of these exudates in section, but nevertheless they appear in a considerable number of the microscopic specimens and their character is always the same; they consist of a more or less structureless mass with blood cells and leucocytes embedded in its substance. In fact, they would seem to be identical with the membrane spoken of by Straub as harbouring the leucocytes which give rise to dust-like and other opacities of the vitreous in his experimental cases. At a later stage, or perhaps in cases where the inflammation has been of a more plastic character, a distinct fibrillation of the exudate can be seen, and there may even be evidence of a definite fibrous tissue formation. If we confine our attention for the moment to the eyeballs in which the exuded mass is devoid of structure in the anterior portion of the cone we shall find that, on tracing it back toward the apex by which it is attached to the optic nerve, it becomes more highly organised and more richly cellular, whilst fibrillation and fibrous tissue formation make their appearance. The same thing, though in a lesser degree, may be observed in the neighbourhood of the ciliary body, doubtless due to the presence of a plastic exudate derived from that structure.

An examination of the optic nerve and of the exudate attached to it reveals the following features: 1. The nerve head is congested and its vessels stand out in prominent

relief. 2. There is a considerable effusion of leucocytes in the neighbourhood of these vessels. 3. A mass of exudate fills up and projects from the optic nerve cup, whether this latter is physiological or glaucomatous. This mass is clearly contracting, and thereby pulling on the tissue which lines the edges of the cup. 4. Along the centre of the projecting exudate are to be seen (a) an abundance of mono-nuclear cells; (b) the commencement of a fibrous tissue formation; and (c) a new formation of blood-vessels.

The appearances above enumerated would indicate that we have to do with an inflammation of the optic nerve, which had been induced by chemotactic substances brought thither along Stilling's canal. Such an idea is not a new one. It was suggested by Straub in order to explain the optic neuritis he found in his two cases of experimental inoculations of the ciliary body, and it also enjoys provisionally the support of Fuchs's<sup>2</sup> authority. The idea that part of the lymph of the eye passes backward along a passage corresponding to the central hyaloid canal is not generally accepted, and rests largely on inference from the observation of pathological specimens. It would be difficult, however, for anyone who has carefully studied this series to doubt that such a flow exists; it is, of course, not suggested that any large percentage of the lymph travels in this direction.

A confirmation of these views is obtained if we refer to the three eyeballs in which the organisation of the cone of exudate into the vitreous has attained the highest development. We notice in these how extremely far this process of organisation has been carried in the apex of the cone, where it is represented as a well-defined opaque cord. (Fig. 23, No. 199, *vide* also Fig. 9.) In one of the three a fibrous band, presumably the remains of the canal of Stilling, is clearly seen, whilst in the two others the existence of this structure is at least indicated. It is possible that in the first named a congenital peculiarity exaggerated the distinctness of the appearance.

#### THE RETINA.

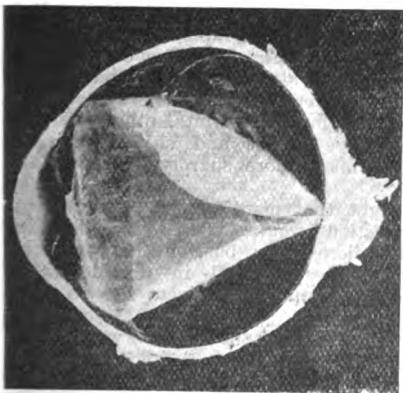

Detachment of the retina occurred in 38 of the 54 globes (70.38 per cent.) and was absent in 16 (29.62 per cent.). It was partial and ill-marked in 5 (9.25 per cent.), extensive in 9 (16.68 per cent.), and complete in 24 (44.44 per cent.). The ocular tension was above normal in 11 out of the 16, which presented no detachment, but in only 6 out of the remaining 38; it was below the normal in 13 of the 24 globes with complete detachment, and above it in 3 of them. In the very great majority of the eyes the detachment of the retina was undoubtedly due to traction from within. The sequence of events is plain from a study of the whole series.

At the operation there was an infection of the coats of the eye and also of the vitreous chamber from without; this led to the formation of inflammatory material within the vitreous chamber; adhesions took place between these new-formed membranes and the retina; finally the shrinkage of the organising inflammatory material tore the retina from its bed. Every step of the process can be traced either in microscopic sections or in the naked-eye specimens. The earliest possible stage is seen under the microscope in sections of an eyeball (No. 37), where in the neighbourhood of the ora serrata the shrinkage of the exudate within the vitreous chamber has just begun to lift the retina from its bed. The individual points of attachment between the inflammatory membrane and the retina are beautifully illustrated. The ultimate stage of the process is to be found in those cases in which the retina is not merely totally detached but has shrunk posteriorly into a stick-like form (*vide* Fig. 16), whilst it opens out anteriorly into a mass, in which the iris, the ciliary body, the lens, the remains of the vitreous, and the retina are inextricably matted and tangled. When sections of such specimens are examined under the microscope their leading feature is the evidence of severe plastic irido-cyclitis, with the formation of abundant cicatricial tissue, which mats all the parts together and severely distorts the normal anatomical arrangement. The retina is dragged forward from the neighbourhood of the ora serrata over the ciliary body, whilst elsewhere it is thrown into abundant folds and completely separated from its normal attachments. A pseudo-cystic condition is thus produced, the apparent cysts being formed by the elaborate folding of the membrane. (*Vide* Figs. 11 and 21.) These may be small and slit-like, or may be large and round, so simulating the appearance of true cysts. In front of the retinal mass lens fragments and capsule are seen in a number of the specimens entangled in

<sup>1</sup> The Pathology of Dust-like Bodies in the Vitreous, &c., Trans. of the Ophthalmological Society of the United Kingdom, 1912, xxxii., 60.

<sup>2</sup> Fuchs: Textbook of Ophthalmology, Duane, fourth edition, 1911, p. 16.

type of inflammation and the more intense the process is, the greater will be the measure of ultimate cicatrization, always provided that the inflammation is not intense enough to result in suppuration.

There are several different ways in which the exudate which forms within the vitreous chamber may be placed in a favourable position for the production of retinal detachment.

FIG. 23.

Right eye, lower half. (199.)

its walls, and thus paved the way for the separation of the membrane. In one of these cases (No. 44) a longitudinal fold was detached, whilst in the other (No. 72) the detachment was broad and shallow.

2. In the second method also it is necessary to postulate an infection of the retina before that membrane could have contracted adhesions, either localised or widespread, to the neighbouring vitreous exudate.

Once, however, the virus was planted within the hyaloid chamber, it probably diffused itself widely, and by means of chemotaxis set up an inflammation of the retina; evidences of such a retinitis abound in many of the specimens. Attachments

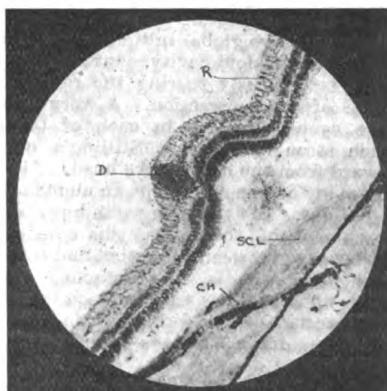

the scar tissue. As has already been said, all grades can be traced from the slightest detachments up to those we have just been describing. The greater or less degree of separation of the retina met with in the different globes is doubtless in part a question of time, but it is also, and probably to a much larger extent, one of the character and grade of the inflammatory process excited in the eyeball. The more plastic the

between the vitreous exudate and the retina having been thus formed, the contraction of the former would naturally lead to the separation of the latter from its choroidal bed.

3. In a few of the globes the contracting membrane is merely an infiltration and thickening of the anterior layer of the hyaloid. It is well known that the vitreous body is, under normal conditions, more firmly attached to the retina in the neighbourhood of the ora serrata than it is elsewhere; it is therefore obvious that an inflammatory contracting membrane in the anterior part of the vitreous will pull throughout its whole circumference on the retina in its neighbourhood, effecting a detachment over a very wide area. (*Vide Fig. 12.*) This is just what we see happening in the globes we are now discussing.

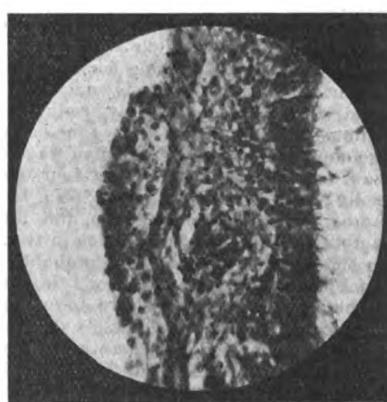

4. In a number of the specimens it can be clearly seen that the bands, which drag upon the retina, radiate from the remains of lens masses, which are themselves encased in inflammatory tissue, and are bound thereby to the iris and ciliary body in their neighbourhood. Such bands appear in some cases to lie in the substance of the retina itself (*vide Fig. 15.*); in others they are situated in the vitreous and present the form of membranous sheets, separated from the subjacent retina only by narrow spaces, and finding attachment to it in the neighbourhood of the equator. (Nos. 117 and 170.) The characteristic of these cases would appear to be that the dislocated lens is in them the principal focus of sepsis within the eye. The point is of interest since some of them, at least, represent ruptured Morgagnian cataracts, for the lecturer has reason to believe, on clinical

Cysts in retina. (111.)

grounds, that the liberation of Morgagnian fluid within the eye is sometimes, at least, productive of considerable irritation to the surrounding parts.

There are two globes in the collection in which the exudate within the hyaloid cavity, converted into organised fibrous tissue, is obviously tearing the retina from its bed in the course of its contraction. A very interesting feature of these eyeballs is that in each of them an opaque band which strongly suggests Stilling's canal can be traced forward from the optic nerve head. (*Vide Fig. 23*)

In many of the specimens an abundant subretinal exudate is present. In the long-standing ones, with complete detachment of the retina, this effusion fills up the whole of the space between the retina and the choroid. When the latter membrane is also detached a further exudate of similar appearance is seen between it and the sclera. Owing to the action of the formalin, the very firm coagulation of the long-standing effusions gives the eyes a solid and very characteristic appearance (*viz.* Fig. 11); the half globes look like sections of marbles made of fused and clouded glass. In earlier cases the effused mass is much less firm, but is whiter and more opaque, with a tendency to present a flocculent appearance. The question that naturally presents itself is, whether these effusions were the cause or the result of the retinal detachment. The presence of the inflammatory exudate within the vitreous, with which we have already dealt, provides such a satisfactory explanation of the detachments of the retina throughout this series, that it seems unlikely that the effusions in question, whether subretinal or subchoroidal, play any causative part whatever.

We must place in quite a different category the cases, four in number, in which the effused fluid consisted of blood. The source of the haemorrhage in these cases is different from that which is met with when the pressure within an eye is suddenly reduced by the operative opening of the globe. In the latter case it is the large choroidal vessels which give way and the haemorrhage is subchoroidal, whereas, in the four cases under review the bleeding was subretinal in one (N. 157), into the vitreous chamber alone in one (Fig. 24), and into both the vitreous chamber and the subretinal space in two. The haemorrhage into the vitreous chamber was probably due to injury to the retinal vessels by the couch's instrument, though it is possible that blood may have found its way through the retinal cut from choroidal vessels divided at the time. The subretinal haemorrhage probably escaped from the severed branches of the smaller choroidal vessels. The fact that in no case was a large subchoroidal haemorrhage present would indicate that the large choroidal vessels were tough enough to escape injury, being probably pushed aside by the comparatively blunt instrument the couch used. In one eyeball (N. 157) large cholesterol crystals were seen shining on the cut surface of the sanguineous mass. A similar phenomenon was observed in the case of one of the albuminous effusions above spoken of.

It remains to deal with a rare cause of detachment of the retina or of the retina and choroid—viz., the application of direct violence at the time of operation. This is best exemplified in the two globes, in which the cataract was thrust through and behind the retina, by the couch's instrument at the time of operation. (*Vide Fig. 13*.) It is also beautifully illustrated by specimen No. 72 in which the retina and choroid were carried in front of the couch's instrument before the latter succeeded in perforating them. (*Vide Fig. 20*.) The dislocation thus produced proved permanent.

#### Dots on the Retina.

A striking feature of the series of specimens before us is the presence of numerous dots on the retina. These are to be seen in 16 cases, and doubtfully in a seventeenth. In at least one other similar dots are present on the choroid and on the posterior surface of the iris. (*Vide Fig. 18*.) We therefore find this peculiar appearance in one case in every three; but this is far from representing what is probably its real relative frequency, for in 24 of the globes the retina was totally detached, and it was therefore impossible to say whether there were dots present on it or not. If we put these 24 to one side, we find that the dots were certainly present in 16 out of 32—that is, in well over 50 per cent. If we include the other two cases above alluded to the figure rises to 60 per cent!

In some of the specimens the dots are so large that they could scarcely be missed under a careful naked-eye examination (*vide Fig. 10*), whilst in others they were only discovered when highly magnified photographs of the eyeballs were thrown on a screen. (*Vide Fig. 9*.) They could, however, be found easily with a loupe once their presence was known. The variation in different specimens was not confined to size; some of the dots were white, others were a pale grey, and a few were bright and shiny. Again, some of them appeared much more sharply defined than others.

It was at first thought that manifestations so distinct under slight magnification would yield very definite appearances under the microscope; but, on the contrary, much difficulty has been experienced in deciding the nature of the changes which have given rise to this phenomenon.

One of the first points noticed was that the dots were found almost exclusively in long-standing cases. This of itself would appear to indicate that their cause was to be sought in some degenerative process; but a closer analysis of the histories revealed a probable fallacy in such an argument, since a number of the eyes had had good vision for a long period after operation, and had eventually succumbed to a fresh inflammatory invasion, or possibly to a more severe recrudescence of a septic condition implanted at the time of operation.

On examination of a number of specimens three distinct appearances have been found, any one of which might presumably account for the dots seen with the naked eye.

1. In some of the globes a proliferative retinitis can be found along certain of the vessels. (Fig. 25.) These consist in section of masses of mononuclear leucocytes surrounding the vessel wall and tending to make their way to the inner surface of the retina. It might be thought that such a change would produce lines rather than dots, and that those lines would run along the course of the vessels, but there are two features which make this doubtful: (a) even under the same field some of the vessels appear quite healthy on section, whilst others show distinct masses of proliferation, and (b) along the course of a vessel cut obliquely one may find the proliferative exudate confined to one part of its course, the rest being comparatively free.

2. In the neighbourhood of some of the inflamed retinal vessels above spoken of, one finds on the surface of the retina what appear to be free collections of mononuclear cells. (Fig. 26.) These are apparently of the same nature as the dots described by Straub on the posterior surface of the cornea and in the vitreous body. It will be remembered that he attributed them to chemotoxic action. It would appear not improbable that the same explanation holds for these retinal dots. It is of interest that though they occur in cases of long standing, the history of a subsequent inflammation, destructive to vision, is of a much later, and indeed of a comparatively recent date. The presence of such exudative masses would then be easily explained.

3. The grouping of these dots varies considerably in different specimens, but does not lend much colour to the idea that they are vascular in origin, for in some at least of the eyes they certainly do not follow the course of the vessels. On the other hand, in a few of the eyeballs there is a massing of these dots in the neighbourhood of the ora serrata, which is in itself suggestive of a degenerative process, since this is the area of lowest circulatory activity, inasmuch as this region is supplied by the ultimate twigs of the retinal vessels. This observation gathers interest from the fact that in quite a number of these specimens it is possible to demonstrate the presence of small cysts in the walls of the retina. (Fig. 27.) These cysts are produced by the coalescence of oedematous spaces in degenerative areas. All stages of the process can be traced in different specimens of the series before us. Such cysts are only likely to be met with in long-standing cases in which the degenerative processes have had time for full play.

Inasmuch as these retinal dots are found in the cases in which the retina is still in its normal position, it would seem probable that a careful clinical search should reveal their presence in living eyes now that their existence is established pathologically. It is a point which should repay the study of surgeons who are practising where couching is commonly resorted to, and especially in India.

## GLAUCOMA.

It has long been known that couching is frequently followed by secondary glaucoma. In the present series of 54 globes, 19 of them showed evidence of high intra-ocular pressure. This figure must not, however, be taken as a reliable index of the numerical frequency of glaucoma as a complication of the operation. On the one hand, we must remember that the present series deals with the failures only, and that a large number of eyes are met with clinically in which the lens is floating free in the vitreous chamber without any sign that the intra-ocular tension is raised. Again, the cases which go on to suppuration, and which are very numerous, are excluded from the present series owing to the fact that all such were eviscerated in order to avoid the risk of intracranial sepsis. This obviously diminishes the total number of globes under consideration, and thereby raises the apparent percentage of other conditions, such as glaucoma. On the other hand, it would be a mistake to suppose that out of these 54 globes only 19 had suffered from secondary glaucoma, for in 24 of them a complete detachment of the retina had covered up any evidence which may at some time have existed of the presence of increased intra-ocular pressure, though the conditions still found in some of them make it more than probable that the globes were formerly glaucomatous. In any case, it leaves us with the fact that out of 30 eyeballs which were available for accurate examination no less than 19 were glaucomatous. In 16 of the 19 the angle of the anterior chamber was extensively closed, and in 3 of these the chamber was so shallow as almost to be reduced to a potential slit. The remaining 3 are thus accounted for; in one the angle was widely open and there was free communication between the aqueous and vitreous chambers; in a second, a Morgagnian lens was impacted in the angle of the anterior chamber; whilst in a third the operation was followed by a very severe haemorrhage, which probably had the direct effect of over-distending the hyaloid cavity at the expense of the aqueous chamber.

Returning to the 16 cases, in which the angle of the chamber was closed, and to certain other eyeballs in which it seemed probable that glaucoma had at some time been present, we found that in every one of them one or other of the accepted causes of secondary glaucoma was revealed when looked for; in some, more than one such cause was discoverable. We shall content ourselves with enumerating these factors.

A corneal fistula, with evidence of past anterior staphylosis, was present in one; in one there was a capsulo-corneal synechia, and in another a retino-corneal synechia; in 5 the ciliary body was involved in the scar; in 6 the dislocated lens pressed extensively on the iris base; in 3 the lenses, tilted at right angles to their normal position, pressed the anterior hyaloid membrane severely back on the side of the dislocation, whilst causing the vitreous to bulge the iris forward into the anterior chamber on the opposite side; in 5 the pupil was blocked, and in 3 of these *iris bombe* was present; in 2 the anterior layers of the hyaloid were so thickened by inflammatory exudate as to suggest that there was an abnormal obstruction to the passage of fluid across the membrane; in one, a marked thickening of the lens capsule in the form of an after-cataract may possibly have provided an obstruction to the forward passage of fluid from the vitreous; lastly, there is one globe in which glaucoma had probably been present before the operation, if one may judge from the history of the case and from the violent haemorrhage which followed the couching.

It has been suggested that one of the causes of glaucoma after this operation is an advance of the front part of the vitreous body owing to a rupture of the anterior layers of the hyaloid during the operation. Without in any way denying that the suggestion may be a valid one in certain cases, the impression, gained from a study of this series, is that we need look no further than the well-recognised causes of secondary glaucoma. We have only to remember that the trauma inflicted is extensive and various, and that a greater or less degree of sepsis accompanies every couching in the hands of its Indian exponents.

## CONCLUSION.

In conclusion, it remains to express my indebtedness to those who have very kindly assisted me in various ways. Professor Keith has done everything in his power to help me. I owe Mr. Mudson my acknowledgments for kindly

cutting a difficult specimen for me and for his advice on its details. Mr. Treacher Collins has generously given me advice and assistance of the greatest value in the study of a number of the eyeballs and of the microscopic specimens made from them. I have acted freely on a number of the suggestions he has been good enough to make. The cutting of the microscopic specimens has been done by Mr. S. Stephenson and by Mr. Chesterman, to whom I am greatly indebted for the care they devoted to them. The photographs, both macroscopic and microscopic, and the lantern slides made from them, as also the stereoscopic pictures, have, with very few exceptions, been taken by Mrs. Elliot, without whose help the present work could not have been done. The exceptions were taken by my late assistant in Madras, Mr. C. Taylor, to whom, as well as to Lieutenant H. C. Crags and all my staff, I am deeply indebted for the loyal assistance they gave me during years of methodical and painstaking work. Major H. Kirkpatrick and Captain W. C. Gray (both of the I.M.S.) have put me deeply in their debt by the generosity with which they have helped me since I left India, placing their material unstintedly at my disposal. Dr. Ekambaram has given me much valuable and carefully gathered information. Messrs. Underwood and Underwood have kindly lent the stereoscopes used for these demonstrations.

## THE AGGLUTINATION CURVE AND ITS IMPORTANCE IN THE DIAGNOSIS OF TYPHOID AND PARATYPHOID FEVERS IN INOCULATED PERSONS.

BY GEORGES DREYER, M.A. OXON., M.D. COPENHAGEN,  
MAJOR, R.A.M.C.; PROFESSOR OF PATHOLOGY IN THE UNIVERSITY  
OF OXFORD;

AND  
A. C. INMAN, M.A., B.M. OXON.,  
CAPTAIN, R.A.M.C.; DIRECTOR OF THE PATHOLOGICAL LABORATORY,  
BROMPTON HOSPITAL.

(A Report to the Medical Research Committee.)

IN February, 1915, one of us (G. D.), in conjunction with Ainley Walker and Gibson,<sup>1</sup> stated that accurate differential diagnosis of enteric group cases can only be obtained by routine testing of the serum of the patient against the three micro-organisms *B. typhosus* and *B. paratyphosus* A and B, in parallel series of observations, and by always determining the maximum dilution of the serum in which agglutination takes place. For individuals who have been inoculated with antityphoid vaccine within a period of some months or even years will, as we have shown, usually give a high agglutinin titre against *B. typhosus*.<sup>2</sup> Whether they are suffering from active typhoid infection or not can only be determined by repeating the agglutination test at intervals in order to ascertain whether the titre of agglutination shows marked changes or remains practically constant.

Further, a technique which had proved satisfactory for the agglutination test over a period of years and in a very large number of tests was re-described in detail. The advantages of this technique lay essentially in the employment of Standard Agglutinable Cultures for the performance of macroscopic tests. From July, 1915, such standard cultures and the equipment for carrying out the test were issued from the Department of Pathology in the University of Oxford on behalf of the Medical Research Committee for the use of the medical services of H.M. Army and Navy.

In March, 1915, we decided to study the agglutinin curves in a series of patients suffering from infection by bacilli of the enteric group, all of whom had been inoculated with typhoid vaccine. The necessary material was kindly placed at our disposal by Lieutenant-Colonel Evans, D.S.O., O.C. Stationary Hospital, B.E.F. A short paper embodying our results was prepared for publication late in the same year. But unfortunately it was destroyed by fire along with the majority of the curves and a mass of other data. Fortunately the data for few of the curves had been preserved in duplicate elsewhere, but pressure of other work has prevented us from reconstructing and publishing our intended article. The knowledge which we gained in the course of the work has, however, formed the basis of a number of

statements regarding the diagnosis of enteric fevers in typhoid-inoculated individuals which have been made in several succeeding publications.

We now propose to publish these surviving curves, with brief comments, as evidence confirmatory of the statements made by one of us (G. D.) regarding the importance of employing accurate quantitative methods in the performance of the agglutination test as applied for the diagnosis of infections of the enteric group in inoculated persons. We shall then be in a position to re-state and explain certain broad generalisations directly emerging from these data on

which diagnosis rests, and whose neglect has recently led Martin and Upjohn to reach conclusions which impugn the value of agglutination tests in inoculated subjects.

It will be convenient to begin by explaining certain terms employed in connexion with the technique of the use of standard agglutinable cultures.

1. *Standard Agglutinable Cultures* are prepared of definite opacity and measured agglutinability from strains of the bacilli concerned which have been specially selected for their high specificity. In successive batches of standard agglutinable culture the relative sensitiveness to agglutination of the

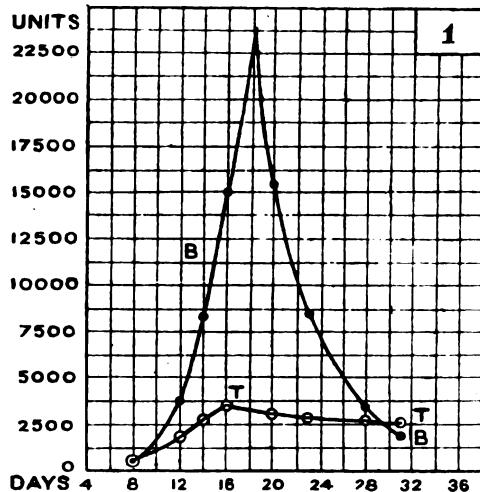

CHART 1.—*Paratyphoid B* occurring in a T.-inoculated individual. The B agglutinins rise rapidly from the first observation on the eighth day of the disease and reach the very high level (unusually high) of more than 15,000 units on the sixteenth day. As seen from the shape of the curve the maximum is even much higher than this and is reached about the eighteenth day. Thereafter the usual regular fall sets in at first rapidly, so that the units have fallen from somewhere about 24,000 to 8600 in the next five days, subsequently more slowly. Meanwhile the T. agglutinins have risen very markedly, though relatively much less. They attain their maximum of about 3500 units about the sixteenth day, some two days before the maximum of B agglutinins, falling from this point in a very gradual but quite regular curve to about 2800 units on the twenty-third day. After the thirtieth day B agglutinins, though still much higher than their level at the first observation, have fallen below the T. agglutinins, the titre in the two cases being 1800 units and 2500 units respectively, showing the greater persistence of the rise produced in the T.-inoculation agglutinins as the result of paratyphoid B infection than in the B agglutinins themselves.

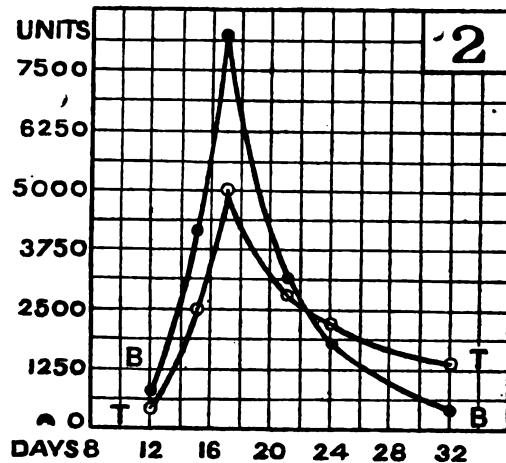

CHART 2.—*Paratyphoid B* occurring in a T.-inoculated individual. This curve is another example of a high agglutinin reaction to paratyphoid B infection. In this case both the absolute and relative increase in T. agglutinins caused by the paratyphoid B infection is greater than in the former example. The B maximum is reached on the seventeenth day, as is also that for T. agglutinins. The fall in T. agglutinins is much more marked than in the previous example, but the titre of B agglutinins falls even more rapidly so that the curves have already crossed on the twenty-third day. On the thirty-second day the B agglutinins stand at about 400 units while the T. agglutinins are 1400 units.

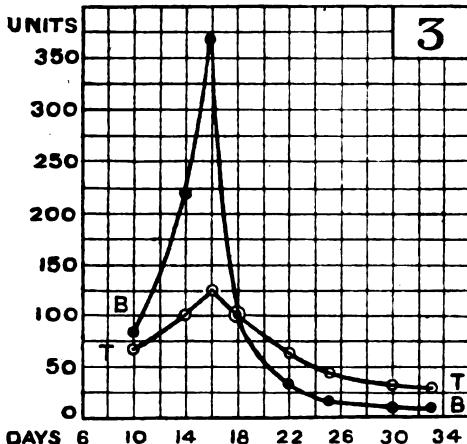

CHART 3.—*Paratyphoid B* occurring in a T.-inoculated individual. This curve shows a moderate agglutinin reaction to paratyphoid B infection. The B agglutinins rise from about 100 units on the tenth day of disease to a maximum of 370 units on the sixteenth day. Thereafter they fall very sharply, and two days later (on the eighteen day) are already down to 100 units. The T. agglutinins undergo a relatively marked rise and subsequent fall, reaching about 125 units on the sixteenth day, and thereafter undergoing a gradual fall and crossed by the paratyphoid curve, which falls below it from about the eighteenth day.

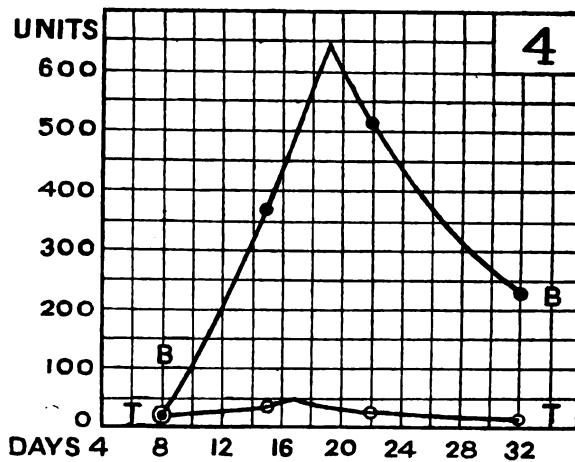

CHART 4.—*Paratyphoid B* in a T.-inoculated individual. This curve is introduced to show a case in which the absolute rise and fall in T. agglutinins caused by the B infection is only small, though the response of the B agglutinins is marked. Here the maximum of the T. agglutinin titre is antecedent (seventeenth day) to that of the B agglutinins (nineteenth day).

bacilli contained is indicated by a figure—the so-called *Reduction Factor*—the original standard agglutinable cultures having been arbitrarily given the figure 2·5 as reduction factor. The reason for this will appear immediately in connexion with the *Standard Agglutinin Unit*.

2. *Standard Agglutination* is the degree of agglutination present in the highest serum dilution in which marked agglutination without sedimentation can be seen by the naked eye.

3. The *Standard Agglutinin Unit* is that amount of agglutinating serum which when made up to 1 c.c. volume with normal saline solution causes standard agglutination on being mixed with 1·5 c.c. of the original standard agglutinable culture and maintained at 55° C. for 2 hours (in the case of dysentery agglutination 4½ hours) in a water-bath, followed by 15 to 20 minutes at the room temperature.

4. The *Reduction Factor*.—The total volume in which the reaction occurs being 2·5 c.c. (1 c.c. of serum added to 1·5 c.c. of standard culture) the original standard agglutinable culture was given the reduction factor of 2·5 to express the sensitiveness to agglutination of that particular culture. All subsequent batches of culture have been given reduction

factors calculated on this basis, thus securing constancy in the agglutinin unit. For example, if a batch of standard culture proves to be twice as sensitive to agglutination as the original standard, so that half the amount of serum produces standard agglutination under test conditions the new standard culture is given a reduction factor of double the size of the original factor—i.e., 5. Thus, whatever be the particular standard culture used to test any given serum the number of agglutinin units found per c.c. of the serum remains always the same, although the dilutions in which standard agglutination occurs will be different. Since when standard agglutination occurs in a serum dilution of 1 in  $x$ , then  $x$  divided by the reduction factor for the particular standard agglutinable culture used gives the number of Standard Agglutinin Units contained in 1 c.c. of the serum concerned.

5. *Readings*.—Owing to the rate at which the dilution increases in the series of tubes employed it will commonly happen that no tube in the series exhibits standard agglutination. If this be so, it will be found in looking along the series that while one tube shows strong agglutination with sedimentation the next succeeding tube shows no

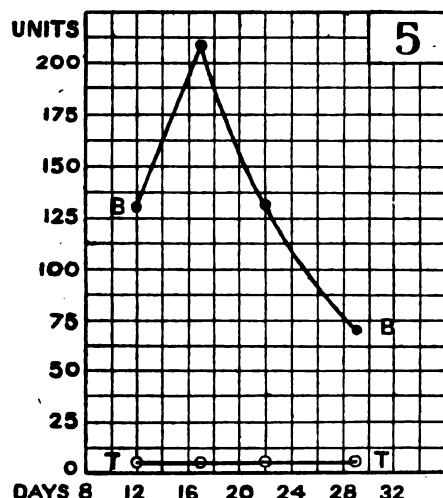

CHART 5.—*Paratyphoid B* in a T.-inoculated individual. This curve illustrates a case in which the T. agglutinin titre which stands at a low level remained unaffected by the B infection, though the B agglutinins reach a fairly high titre and show the usual curve of rise and fall, the maximum being reached on the seventeenth day.

CHART 6.—*Paratyphoid B* in a T.-inoculated individual. This curve shows one of the rarer cases of paratyphoid B in which the response of B agglutinins is small in absolute measure, though exhibiting the usual diagnostic rise and regular fall of active infection. The T. agglutinins are at a high level, but move very little in response to the B infection. Their maximum is reached about the eighteenth day, while the B maximum falls about the twenty-second day at a height which reaches only 20 units. From this point it falls steadily.

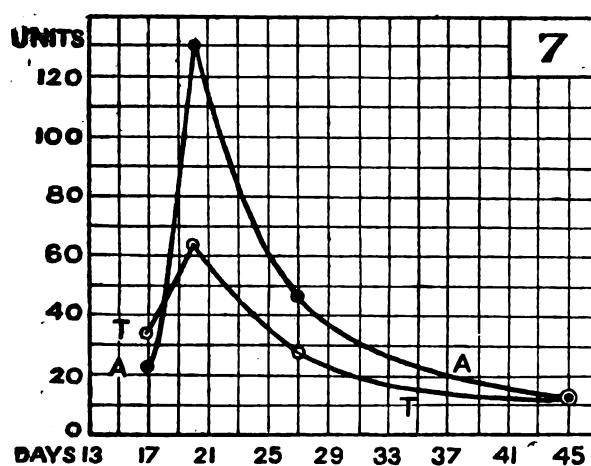

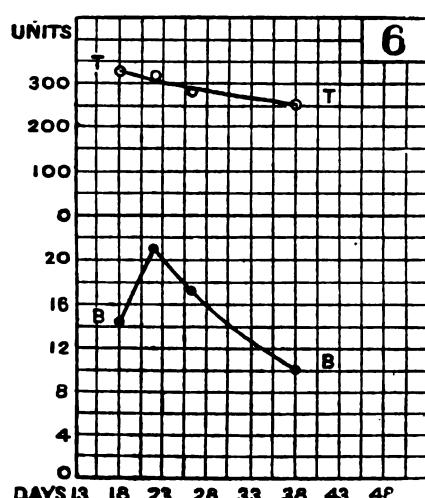

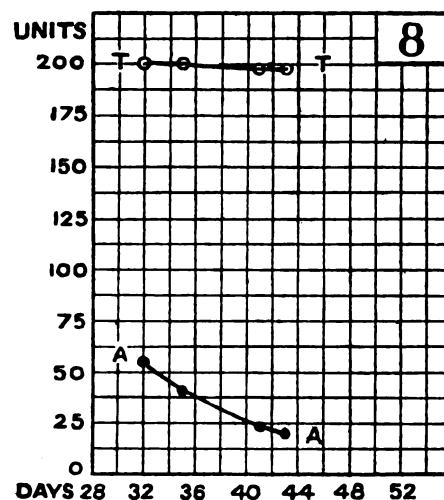

CHART 7.—*Paratyphoid A* in a T.-inoculated individual. The agglutinins rise rapidly from about 20 units on the seventeenth day of disease to their maximum of about 130 units on the twentieth day. Thereafter they fall rapidly to reach the level of about 45 units on the twenty-seventh day. The further course of the curve is shown in the chart. The T. agglutinins show a marked relative rise and fall with a maximum of about 64 units on the twentieth day. The fall is less steep than that of the A agglutinins.

CHART 8.—*Paratyphoid A* in a T.-inoculated individual. A late case. The T. agglutinins are at a high level, remaining practically unaffected by the A infection at a titre of about 200 units. The A agglutinins show a steady fall from 56 units on the thirty-second day of the disease to 20 units on the forty-third day.

agglutination or only a trace. In such cases standard agglutination lies approximately midway between the two dilutions. Though this method of making readings is amply adequate for diagnostic purposes it will be found that should a more precise determination of the limits of agglutination be required it can be obtained by using a stand of 12 tubes with the series of quantities given in the table contained in the Directions for Preparation and Standardisation of Agglutinable Cultures, where the successive dilutions of the serum only differ by about 20 per cent. Almost as accurate a reading can, however, be obtained with experience from the short series by taking note of the degree of agglutination present in each tube and by using a suitable interpolation table. This method has been used by one of us (G. D.) for a number of years, but was not introduced into the Directions for the Use of Standardised Agglutinable Cultures in order to avoid the appearance of unnecessary complications. But since it has been found of assistance by a number of workers to whom it has been privately communicated, especially where large numbers of cases had to be examined, it is now published here.

The principal terms employed in describing the different degrees of agglutination met with are "total" (t), "standard" (S), "trace" (tr), and "nil" (0). Total agglutination indicates the condition in which the whole, or practically the whole, of the agglutinated bacteria have settled down at the foot of the tube. Standard agglutination has already been described; the term Trace is applied to a very fine granulation recognisable by the naked eye. Around these main terms subsidiary differences congregate themselves as follows: Total minus (t -) marked deposit, but a number of floating flocculi remaining in the fluid. On each side of "standard" we find Standard plus (S +) and Standard minus (S -) respectively. In the former no deposit, but much larger flocculi than are seen in standard agglutination. In the latter finer agglutination than standard, with more the appearance of granulation in the fluid. Similarly, we recognise a Trace plus (tr +) and a Trace minus (tr -), the former representing something more than trace but less than standard minus, the latter being on the limit of naked-eye visibility. Finally, on occasion it can be difficult to decide with certainty whether a given tube is absolutely nil or not, the term query trace (tr?) is then applied.

These terms were originally worked out in the course of investigations in which long series of tubes were employed, since it was found that differences of the extent of those described were recognisable; and it appeared that if an ideal series was put up in which the dilution of the serum increased and diminished on each side of the tube presenting standard agglutination by some 12 to 15 per cent, it presented in successive tubes between total agglutination and nil all these different degrees of agglutination. Accordingly the following interpolation table was calculated:

t 1.46	S + 1.13	S - 0.88	tr 0.68	tr? 0.53
t - 1.29	S 1.00	tr+ 0.78	tr - 0.60	0 0.46

The table is used as follows. Supposing no tubes in the series shows S agglutination, but we have t- agglutination 1 in 250, and tr agglutination 1 in 500. It follows from the first of these readings that S agglutination would be found in a dilution of  $250 \times 1.29$ , i.e., 323, and from the second

reading S agglutination should be found in a dilution of  $500 \times 0.68$ , i.e. 340. The average of these two figures (331) is taken as the dilution which gives standard agglutination, and this number divided by the reduction factor of the culture used gives the number of standard agglutinin units per c.c. of the serum examined.

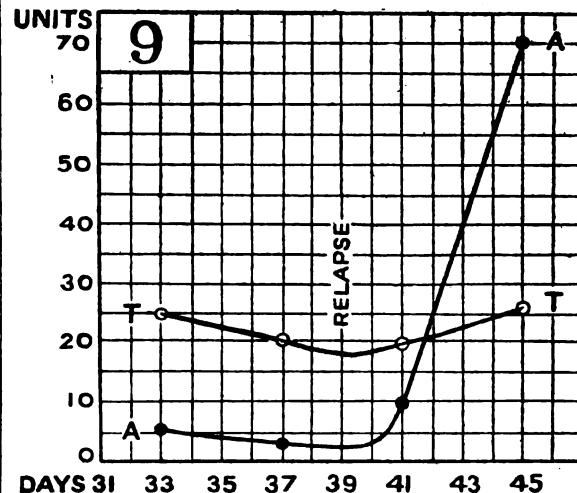

CHART 9.—Paratyphoid A in a T.-inoculated individual, where the original attack was followed by a relapse. This case is specially instructive since it illustrates both the fact that the development of agglutinins in paratyphoid A infection often only reaches a low titre, even at its maximum, and the fact that in a relapse of this infection there is frequently a very marked development of agglutinins. The T. agglutinins rise slightly with the original A infection, but in this case there is only a feeble T. response to the A relapse.

The figures from which the curves here given are drawn were arrived at by this method of making readings. In every case quoted the diagnosis was confirmed by the isolation of the infective organism from blood, stool, or urine. In the curves the actual observations are represented either by a dot or a ring. The dot mark is always used to indicate the curve produced by the infecting micro-organism.

These charts show how the enteric infections may be diagnosed in inoculated persons, by carrying out successive observations of the exact agglutinin titre of the serum for T., A, and B at suitable intervals (of about four days). They also show how entirely misleading it would be to draw conclusions from a single observation of the height of the titre since in many instances the titre for the infecting micro-organism may be found less than that for the inoculation

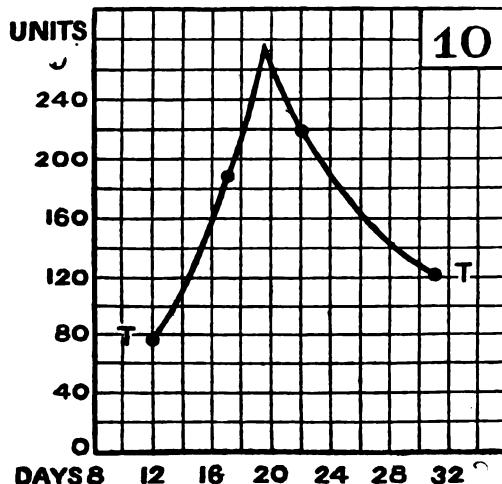

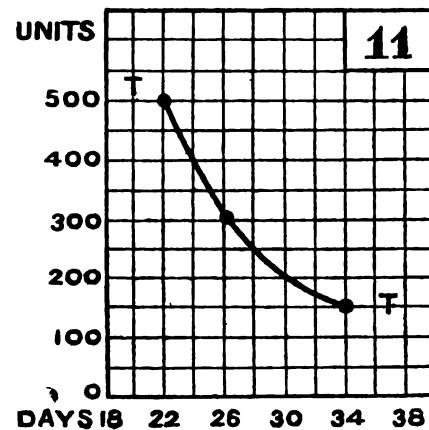

CHART 10.—Typhoid fever in a T.-inoculated individual. The curve shows the typical rise and fall in agglutinin titre, the maximum being reached about the twentieth day.

CHART 11.—Typhoid fever in a T.-inoculated individual. A late case. There is a typical fall in T. agglutinins from the first observation on the twenty-second day of the disease, when they stand at 500 units, to the last observation on the thirty-fourth day, when the agglutinin titre has fallen to 150 units.

agglutinins, and may indeed be lower throughout the whole infection. On the other hand, it is certainly the case that at its maximum the titre for the infecting micro-organism will usually exceed the titre of inoculation agglutinins even though these may be greatly raised as a result of the infection. Nevertheless, as the fall in titre proceeds the curve of A and B agglutinins falls more rapidly than the curve of T. inoculation agglutinins, so that the latter is cut by the former at some points in the fall.

The maximum agglutination titre for the infecting organism most frequently occurs about the eighteenth to twentieth day, and almost always lies within the limits sixteenth to twenty-fourth day of the disease.

As regards the effect of active paratyphoid infection on the typhoid inoculation on agglutinins one of three things may occur: (a) The titre may remain unchanged throughout the infection; (b) it may undergo a rise of moderate extent; (c) it may undergo a marked rise. When such rises occur it is found that they are either synchronous with or antecedent to the rise of agglutinin titre for the infecting micro-organism, and that the maximum falls somewhat earlier than the maximum for the infection agglutinins (or occasionally at about the same time). The change in T. inoculation agglutinins associated with paratyphoid infection is in general much more marked in the case of paratyphoid B than in the case of paratyphoid A.

In view of what has here been shown, it is obvious that it would be quite futile to try to fix a limit of agglutination titre for T.-inoculated individuals, and to proceed to diagnose cases which showed higher titres (even many times higher) as cases of active typhoid infection. The final guide in all these cases of enteric infection is the relative extent of the rise and fall in agglutination titre for the organisms concerned, together with period when the maximum titre is reached.

In a recent article by C. J. Martin and W. G. D. Upjohn these authors emphasise the existence of numerous difficulties in the diagnosis by agglutination tests of the enteric fevers in typhoid-inoculated persons. These difficulties might readily have been avoided had they taken cognisance of what has been repeatedly and clearly stated on this subject.<sup>3 4 5 6</sup> And they would have been saved from the conclusion that since the introduction of triple inoculation (T., A, B) "the interpretation of observations upon the agglutination of enteric organism will ..... be too difficult to possess any practical value, and the isolation of the infecting organism must be resorted to for diagnosis."

In a subsequent article it will be shown that although the difficulty of diagnosis by agglutination tests is to some extent increased by triple inoculation the validity of the tests is in no way impaired. They remain not only the most certain method of diagnosis, but form, in fact, the only method which can be relied upon if a large proportion of the cases are not to be missed. For it is well known that isolation methods fail to detect the infecting micro-organism in blood, stool, or urine in a majority of all cases of typhoid and paratyphoid fevers.

**NATIONAL ASSOCIATION FOR THE PREVENTION OF INFANT MORTALITY.**—A course of advanced lectures on infant care is to be given under the auspices of this association at the College of Ambulance, 3, Vere-street, London, W.C., on Mondays from March 12th to June 18th inclusive. The lecture hour is 5.30 P.M. The course is in preparation for the advanced certificate given by the association, and is intended for teachers and infant welfare workers. The theoretical lectures are supplemented by tutorial courses at various training centres in London. Particulars may be obtained from the secretary, Miss Halford, at 4, Tavistock-square, London, W.C.

## A SIMPLE ULCER OF THE OESOPHAGUS PERFORATING THE DESCENDING PORTION OF THE AORTIC ARCH AND CAUSING FATAL HÆMATEMESIS.

BY J. B. CHRISTOPHERSON, M.A., M.D. CANTAB.  
F.R.C.P. LOND., F.R.C.S. ENG.,  
DIRECTOR OF THE CIVIL HOSPITALS OF KHARTOUM AND  
OMDURMAN, SUDAN.

SIMPLE ulceration of the oesophagus is, clinically, a rare condition, it is probably present more often than diagnosed, but death from the perforation of a latent ulcer of the oesophagus into the aortic arch must be very rare.<sup>1</sup> I beg, therefore, to take the liberty of recording this case. Of all parts of the alimentary canal in man ulceration is least commonly met with in the oesophagus.<sup>2</sup> A few cases of simple "peptic" ulcer of the oesophagus have been reported—one only is recorded which perforated the aorta. The following account is of a case of fatal haematemesis in an Englishman aged 36, which occurred in July, 1916, at Khartoum, and was due to the ulcer perforating the descending part of the arch of the aorta. The clinical history is as follows.

On July 21st, 1916, the patient consulted a medical man because he had, he thought, "something in the throat" and, as he had first noticed it after dinner on the previous evening when he had partaken of a dish of soft fish, he thought that he might have a fish-bone lodging in his throat. There being no clinical evidence of fish-bone or foreign body he was put to bed and given expectant treatment. His symptoms were as follows. He felt as if there was "something in the chest"; he felt it when he swallowed, more especially when he swallowed "nothing" and also when he drew a deep breath. He located this sensation, which was more discomfort than pain, inside the chest behind the sternum, at a place which would correspond to the level where the ulcer was eventually found. He also had some pain behind, which he located between the shoulder-blades. He had a thickly coated tongue; it was always thickly coated, he said, and the thermometer registered 100° F. on admission. There was nothing to be seen in the throat, no physical signs of anything amiss in the chest, and, in fact, the only symptom indicating that there was anything wrong were a rise of temperature to 100°, a coated tongue, and discomfort, sometimes amounting to a little pain, on swallowing or drawing a deep breath.

I am emphasising the total absence of serious symptoms, because seven days after the time when he first consulted a medical man about these small symptoms he had a large haemorrhage, and one day after this the fatal haemorrhage occurred. On July 23rd, the temperature being normal and the symptoms having almost disappeared, the pain having become diffused amongst the muscles of the back, as he said, he returned to his own house. On the 25th he was still having discomfort in swallowing and was admitted again into hospital. Again the temperature was 100°, and again it dropped to normal on the following day and remained so, and on the morning of the 28th, when I asked him to swallow a mouthful of water and also to draw a deep breath and tell me whether he had pain and where, he, after thinking for some time, said in both instances, "Well, I really cannot say that I feel anything at all now." I wish still to emphasise the absence of symptoms and physical signs, because we have reached the very day of the first haemorrhage, which was nearly fatal, and the day before the fatal haemorrhage; and yet, although the ulcer must already have attacked the aorta and was progressing and on the verge of perforating, there was nothing to indicate it but a dirty tongue and a little discomfort in the chest.

At 4 P.M., on July 28th, whilst reclining in a large chair, the patient brought up a little mucus streaked with blood. He was put back into bed. At 6 P.M. he vomited half a basinful of blood, clotted and fairly bright, which had evidently been retained in the stomach. No further visible haemorrhage occurred for 24 hours; evidently the opening into the aorta being a small one became plugged by a clot (this was seen post mortem). The patient seemed to be doing well and he was kept under morphia and given nothing which

<sup>1</sup> Osler (Principles of Medicine, eighth edit. i-n., p. 473): "Tleton collected 40 cases of peptic ulcer oesophagus (first described by Albers 1839). Six perforated the oesophagus and one perforated the aorta with fatal result."

<sup>2</sup> This immunity of the oesophagus is due to the fact that, taking very little part in digestion, it is simply a connecting tube of comparatively simple structure, vertical in position, and being accommodated in capacity it allows of the rapid transit of foodstuffs through it. It is therefore not much exposed to the danger of contracting disease from outside sources.

would tend to raise the blood pressure. The question of a gastrotomy was discussed and dismissed. In point of fact, as was subsequently found post mortem, the situation of the ulcer was inaccessible to operation. On the 29th, 24 hours after the first large haemorrhage at 6 P.M., he had another large haematemesis, evidently blood which had accumulated in the stomach having trickled down from the ulcer, and he died one and a half hours afterwards.

At the necropsy it was found that the haemorrhage came from an oesophageal ulcer which had become adherent to the descending part of the arch of the aorta, in the neighbourhood of the bifurcation of the trachea (Fig. 1), and which had

FIG. 1.

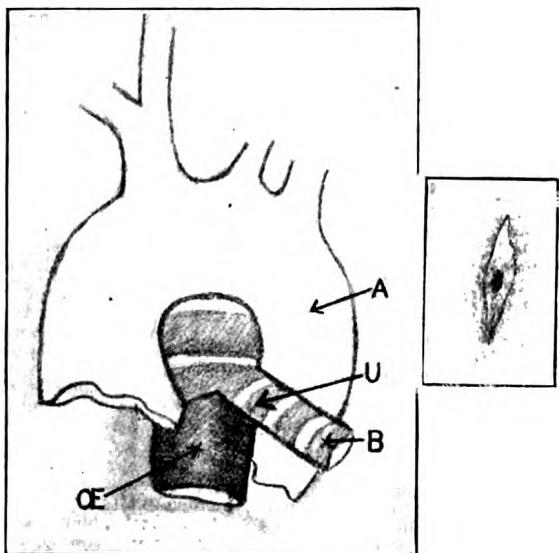

Diagram to show approximate size of ulcer (U) in oesophagus (OE) and the relation to it of the descending part of the arch of the aorta (A). B, left bronchus. A drawing of the ulcer perforating the aorta just behind the left bronchus is attached to the diagram.

penetrated the arterial wall. The stomach was very much distended, containing two or three pints of blood which had found its way down from the ulcer into the stomach and distended it. There were two other ulcers in the oesophagus, both situated at the cardiac end just within the oesophagus, one of which had healed with a cicatrix and the other, a larger oval one, in the process of healing. (Fig. 2.) Sometimes he had complained of a little pain in the epigastrum, and the situation of these ulcers would perhaps account for this. The stomach and all the other organs were healthy. The liver weighed 2½ lb., the spleen 2½ oz. The liver and spleen were examined particularly because the patient was said to have had kala-azar some years ago. In appearance they presented nothing abnormal (excepting the spleen, which was unusually small).

Non-malignant ulcers in the oesophagus are rare; they may be classified as follows:—

1. *Traumatic*.—Corroding fluid (swallowing of); sharp instruments (injury by); foreign bodies (such as fish-bone) blows, violence (bruising by).
2. *Latent ulcer*.—Which may perforate just as gastric ulcer.
3. *Specific*.—Syphilitic.
4. *Secondary ulcers*.—During the course, or as sequelæ, of diseases such as typhoid, kala-azar, diphtheria, scarlet fever, or pneumonia.
5. *Aneurysmal*.—Due to an adjacent aneurysm of the aorta, or other great vessel, ulcerating into the oesophagus.

The (1), (3), and (5) classes may be excluded at once in the present case.

(a) There was no history of anything which could have produced a traumatic lesion, not even a fish-bone; the other two small ulcers (nearly healed) at the cardiac end of the oesophagus are in themselves sufficient evidence against the perforating one being traumatic—both were chronic ulcers in the process of healing, and the fatal one was also a chronic ulcer. Perforating chronic ulcers (peptic) have been described in the oesophagus. They are rare; only a few cases are described.<sup>3</sup> Albers first

described them in 1839. Tileston collected 40 cases; six perforated and one perforated the aorta.

The same conditions do not exist in the oesophagus as in the stomach to give rise to ulceration. So that simple oesophageal ulcer must be a diagnosis based to a large extent on a process of exclusion. A definite diagnosis is, I think, impossible to make until haemorrhage takes place.

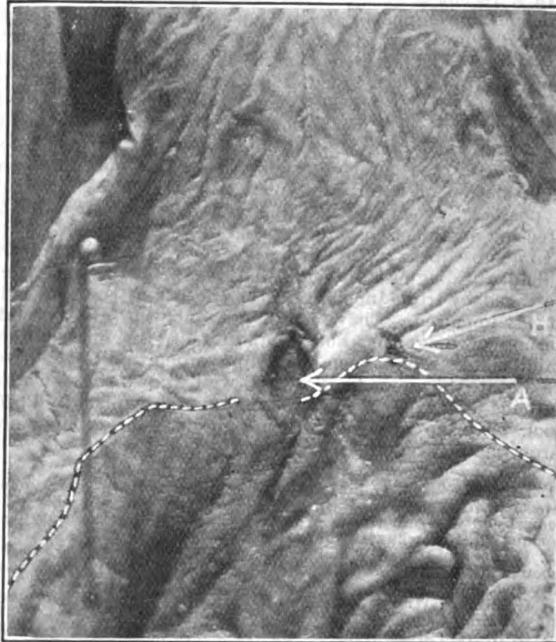

(b) Nor was it a syphilitic ulcer. There was no evidence at all to favour such a diagnosis.

(c) There was also not a single particle of evidence in favour of a diagnosis of aneurysm. Seen post mortem, the wall of the aorta was perfectly normal and healthy, except where the perforation was, and the patient had not had syphilis. His urine and kidneys were perfectly normal, and he had no aneurysm-producing disease.

There remains Class (4)—ulceration due to complications and sequelæ of former illness. Two possibilities suggest themselves in this case. The patient is said—I am bound to say on unconvincing evidence—to have contracted kala-azar in 1907. Now, ulceration of the intestines is a common complication of kala-azar, so it is worth while pausing just for a moment to consider this possibility. Suppose, for the sake of argument, that he did contract kala-azar in 1907. After his return to the Sudan in 1908 up to the time of his death in 1916 he appeared perfectly free from any suspicion of it, and at his death the spleen weighed only 2½ oz. and the liver 2½ lb. This, in addition to the fact that ulceration of the bowels is a late complication in kala-azar when the patient is very thin and weak, sufficiently, I think, disposes of the kala-azar theory.

There remains the theory of typhoid ulceration and sequelæ, and I must say at once that the evidence appears

FIG. 2.

Photograph of junction of oesophagus (above the line) and stomach (below the line) showing the two ulcers, one healed (H), the other active (A), situated just within the oesophagus.

to me in favour of this diagnosis—sequelæ after typhoid, although it was six years after the attack of typhoid fever. The two lower ulcers exactly corresponded to healing and healed typhoid ulceration (Fig. 2). The ulcers were chronic, and the symptoms were insidious and probably had lasted over a long period, giving time for the aorta to become adherent to the oesophagus. The appearance of the ulcers was oval in the long axis, base granular, surface shallow, edges smooth and overhanging, margins level, and not irregular and heaped up. (Fig. 1.)

The evidence—partly exclusive, partly of local appearance, partly of history—and the circumstances point to old typhoid ulceration. This is the opinion I myself hold, for it is the

only opinion which is, I think, consistent with the facts. Still an ulcer, of whatever origin, of the oesophagus, situated at the part which is in relation to the aorta so that it perforated, causing fatal haemorrhage, is rare. It might fittingly be placed in the category of "accidents of medicine." Six years had passed since the patient had had the typhoid fever, but the attack had been a severe one, and although the ulcers at the time of death may not have been specific in the sense that they were infected with Eberth's bacillus, still an old ulcer whose base had become fixed to the aorta might, owing to the strain of gymnastics or polo, resume activity, and this is how I view the case. A few days previous to his illness the patient had complained of some discomfort in the chest after gymnastics, and I think that probably this lighted up into activity an old ulcer which was adhering to the aorta—a sequela of typhoid six years previously. The original attack of typhoid, I am informed by the medical man who attended, was typical and serious. The patient had haemorrhage and he was carefully watched for perforation, and convalescence was long.

From general and microscopical appearances the ulcer was an old one. The aorta was with difficulty separated by dissection from the oesophagus in the neighbourhood of the ulcer, showing chronicity. The inflammation from the base of the ulcer had fixed the aorta to the oesophagus, and under the microscope there was an arteritis round the perforation in the aorta. The aorta having become fixed to the base of the ulcer as inflammation proceeded, it became in its turn the base and was involved in the processes going on. As ulceration slowly proceeded the artery became the floor of the ulcer; then softening of the arterial wall occurred and perhaps a little bulging (the arterial wall round the perforation was funnel-shaped and thinned, as if it had been bulging at this point). The bulging occurred, perhaps, when the patient had been doing gymnastic exercises on the day previous to admission. Then came ulceration of the aortic wall forming the floor of the ulcer, and the occurrence of the streaks of blood in the brought-up secretion, and two hours later perforation and the large haemorrhage on July 28th. Then the cessation of the haemorrhage caused by plugging of the small perforation by blood clot, and, finally, after an interval of 24 hours, the displacement of the cork of blood clot and fatal haemorrhage.

The above appears to have been the pathological sequence of events. There remains, however, the cause of the oesophageal ulcer. The general appearance of the ulcer itself, the presence of the two other ulcers, one quite healed and the other healing, at the cardiac end of the oesophagus, the noticeably coated condition of the tongue which the patient said he always had, would suggest that these ulcers had been present for a long while, and it is surprising that they gave rise to practically no symptoms. Perhaps they owed their origin to the attack of typhoid fever in 1910. This is likely, but there is no direct evidence. Perhaps it was a simple streptococcal ulcer, such as one meets frequently in the stomach, and much less frequently in the oesophagus.<sup>4</sup>

The case is, I think, remarkable not only for its rarity, but also on account of the total absence of serious symptoms up to 26 hours previous to death, when some streaks of blood were noticed in some secretion which the patient spat out.

The only subjective signs were a certain degree of discomfort, not amounting to pain, in the chest on swallowing, especially on performing the act of swallowing without swallowing anything in particular, and also in drawing a deep breath.

The objective symptoms were a noticeably foul tongue (which the patient said he always had) and a small rise of temperature, never over 100°, which twice descended to normal after 24 hours in bed.

From this case one may learn that a quiescent chronic oesophageal ulcer may cause no symptoms at all if we except the coated tongue. When the process becomes active there will be discomfort or pain located indefinitely about the level of the ulcer back and front. It is only when perforation into a vessel, organ, or cavity occurs that a definite diagnosis can be made. Perforation into a vessel large or small, causes obvious symptoms. Perforation into the left pleural cavity, which, I take it, is the commonest site of perforation for an

oesophageal ulcer, causes symptoms (subjective) very similar to those produced by perforating gastric or duodenal ulcers; but the physical signs in the one case are those of acute respiratory trouble (pleuritis), in the other acute abdominal (peritonitis). In the account of such a case of perforating oesophageal ulcer into the left pleural cavity by Dr. Graham W. Christie<sup>5</sup> two clinical points stand out and seem worthy of note: (1) The sudden pain and subjective symptoms caused by the perforation of an oesophageal ulcer into the left pleura suggested peritonitis, though in reality they were due to pleuritis, as was shown by absence of signs of general peritonitis; and (2) in perforating oesophageal ulcer the patient can sit up more comfortably than he can lie down, the opposite being the case in perforating gastric ulcer.

I have to thank Mr. Newlove, pathological assistant, Khartoum Civil Hospital, for helping me to put this little paper together.

Khartoum.

## CHRONIC EMPYEMA: THE VALUE OF DECORTICATION OF THE LUNG.<sup>1</sup>

BY W. H. BATTLE, F.R.C.S. ENG.,

LIEUT.-COL., R.A.M.C. (T.); SENIOR SURGEON TO ST. THOMAS'S HOSPITAL.

In this war there have of necessity been a large number of cases of penetrating wounds of the chest. In many of these there has been an accumulation of blood in the pleura of the side wounded which has cleared up after simple rest in bed. When dyspnoea, cough, or pyrexia has developed paracentesis has been most useful in effecting relief in the symptoms and a quick convalescence. There have been several excellent communications from the medical side which bear out this statement. Sometimes septic infection of the wound has been such that suppuration has taken place in the pleura, and the decomposing clot (and pus) has required evacuation through an incision into the pleura followed by drainage. When this operation has included resection of part of a rib, thus securing a larger opening, the result has been more uniformly satisfactory. In a smaller number closure of the empyema has been incomplete, and a sinus has remained which has proved a source of much discomfort and disability to the patient. Here there will usually be found a cavity of varying size in the pleura, the dimensions of which can be defined by means of a bullet probe, auscultation, and the X rays. This requires exploration under anaesthesia, with enlargement of the track, possibly combined with excision of overlying rib to ensure good drainage. The injection of bismuth paste has succeeded in some instances of moderate sinuses in civilian practice in effecting a cure, but until exploration has proved that no foreign body is there, and no fragment of bone is concealed behind the lowermost rib, its employment is not satisfactory after gunshot wounds. The cases in which the lung has not expanded after the first operation, remains collapsed and bound down to the side of the spine, are luckily few and far between. They are the most serious.

For the cure of an empyema of the most intractable kind, one in which the whole lung is bound down to the inner aspect of the chest cavity, and cannot expand, we have a difficult problem to solve. We are confronted by a cavity the walls of which are rigid and cannot come together to close the space, the ribs are unyielding and the lung so fixed that it cannot expand. It occupies a small part of the chest cavity and is quite functionless. With this local condition there is often a serious general state of exhaustion and emaciation owing to the effects of a prolonged discharge on a system already weakened by an attack of acute disease, or the severe shock of the wound of an important region. The state of the patient will naturally vary according to the duration of the mischief, the intensity of the infection, amount of purulent discharge, and accompanying pyrexia.

The fact that a lung might be released by removal of the covering membrane was not realised until recent years. We had to rely on operations calculated to permit an area of chest wall, which was adapted to the size of the suppurating cavity, to fall in to the level of the lung, from which no aid

<sup>5</sup> THE LANCET, 1915, ii., 17. Case of Perforation into Left Pleural Cavity (male, aged 60).

<sup>1</sup> Abstract of a Clinical Lecture delivered on Jan. 10th, 1917.

was expected. This object was attained by removal of some of the osseous structure of the chest wall, as advised in the operations known by the names of Estlander, Schede, and Depage. In the worst kind of empyema, where the cavity extended to the dome of the pleura, portions of the ribs had to be removed from the lower part of the cavity to the apex. This procedure could not be completed safely at one sitting on account of the attendant shock. Most of us have done one or more of these operations, but with reluctance, for they are mutilating and appear very cruel during their performance. Yet they have been often instrumental in saving life, and ensure closure of the empyema. They resulted, however, in a serious deformity of the chest, and in young people lateral curvature was certain to develop. The most important drawback, however, was the permanent loss of the use of the collapsed and imprisoned lung. The patient was sadly handicapped for the rest of his life by this. Occasionally this operation was accompanied by so much shock and loss of blood that he did not long survive it.

Of these operations the one which is known by the name of Schede has proved most useful, because not only are the ribs excised over the cavity to be obliterated, but the soft structures which have shared in the inflammatory changes which have spread through the costal pleura and become rigid, are also taken away. The remaining soft parts then fall in easily and do not form a rigid wall during later life. Failure generally resulted from inadequate removal of bone.

It is not easy to say to whom the idea of freeing the imprisoned lung, and so obtaining the restoration of what was for all purposes a lost organ, and at the same time a cure of the disease, first occurred. It may be that the possibility of this presented itself to many surgeons and pathologists at various times and in different countries long before the operation was put to the test. In these strenuous times it is not possible to go very closely into the history of the operation. It may be mentioned, however, that Terrier<sup>14</sup> states that Cornil first made the observation that the lung when bound down in chronic empyema could be relieved by removal of the overlying membranous layers so that it might once more expand. The application of the idea to operative surgery is rightly credited to Dr. G. Ryerson Fowler,<sup>1</sup> who operated for the first time on Oct. 7th, 1893. He independently came to the conclusion that the fixation of the lung in cases where it did not expand in old empyema was due to a greatly thickened pleural covering which could be safely removed.

His patient was a man who had been ill for two years and the result fulfilled his anticipations. The lung was retracted to the costo-pulmonary angle above the third rib. "The pleura was isolated by blunt dissection in the direction of the diaphragm until the latter was reached, then peeled off from the latter till the limit towards the mid-line was reached, when it was found to rest against the displaced pericardium, from which, after much difficulty, it was finally detached. This dissection was greatly impeded by the movements of the diaphragm, as well as those of the heart. It was completed by lifting the mass and finally detaching it from the lung above." Considerable expansion of the lung at once ensued and in 24 hours there was vesicular murmur to the level of the seventh rib.

Delorme,<sup>2</sup> to whom Dr. Lund<sup>14</sup> thinks most of the credit should be given for the introduction of the operation, made some experiments on the cadaver with a view of finding a better method of treating old empyema. He reported the results of his experiments to the Congrès Français de Chirurgie about April, 1893. His first operation was performed on Jan. 20th, 1894. The empyema was a tuberculous one and the patient died. His conclusions as to the possibility of freeing the lung have been fully confirmed. It is unlikely that Fowler knew of the experiments of Delorme, and therefore he is entitled to the credit which rightly belongs to the surgeon to whose initiative we owe an improved and successful method of operation for an intractable disease.

At intervals since the publication of Fowler's successful case, contributions have been made to various professional journals in other countries, to which reference can be made by those interested, which confirm Fowler's original estimate of the value of decortication. Modifications have been suggested which have lessened the severity of the operation which he performed at first, thus diminishing the shock produced, which is about the same as that which follows the operation of Schede.

Delorme<sup>2</sup> made a square flap from before backwards, the upper and lower margins following the lines of the third and sixth ribs. This was turned back on the soft parts as a hinge, which was at the anterior border of the scapula. It was afterwards replaced. It has been advised (probably from want of appreciation of the toughness of the enclosing envelope) that incisions sufficient to admit of fingers entering to separate the adhesions should be made. Much time will, however, be saved by the rapid formation of a flap of sufficient size to permit of certain and quick manipulation of the membrane to be removed.

The best time to perform the operation is when a patient with an empyema has recovered from the effects of the operation for evacuation of the pus, and there are still no signs of expansion of the lung. It has been successfully carried out more than three years (O'Dowd) after excision of a portion of rib followed by drainage. The lung even then expanded well and quickly.

In many it is inadvisable to remove ribs, or if sections of the ribs are removed the periosteum and muscles, with other soft parts, may be left. The lung expands in a surprising manner, and of itself may fill up the chest cavity. The importance of the maintenance of a rigid chest wall is evident.

The management of the partly organised material which covers the costal pleura and lung will vary, and surgeons recognise that it is unnecessary to strip off the casing from the pleura and diaphragm as well as from the lung. The object of the operation is to permit of expansion of the lung, and that is effected by limiting the stripping to the covering of the lung itself and the pleura adjoining where the new membrane is thickest. It is not needful to remove the whole of the covering of the costal pleura with the thickened costal pleura also as at first advised. This may be left untouched; the duration of the operation is thus shortened, the loss of blood diminished, and the shock rendered less severe.

The membrane which holds down the pleura may be very thick or very tough, therefore the difficulty in finding the lung will vary. It has been described as over one inch in thickness in one case. The incision should be made into it towards the posterior aspect, commencing above and deepened till the bluish-grey colour of the lung is seen; it is then prolonged to this depth for a varying distance with a pair of blunt-pointed scissors, and the lung at once begins to push through. By taking hold of the membrane on the posterior and then on the anterior aspect of the incision, beginning towards the apex, the whole lung is cleared. The amount of immediate expansion is often considerable, and the lung tends to fill the cavity in a few minutes; for this reason the more accessible parts should be left until the last. The haemorrhage is slight.

Ransohoff<sup>8</sup> has advised that the membrane should be treated by the making of multiple incisions (described as "division of pleura" and "gridironing") at right angles to each other, about a quarter of an inch apart, down to the lung. In cases where there is close adhesion to the visceral pleura this might prove of advantage, especially in tuberculous disease.

The loose attachment of the membrane in most patients renders its complete removal easy, and expansion is more complete. Slight injury of the lung in the process of stripping is of little importance, and haemorrhage is not great. One case of non-expansion during operation is recorded. Possibly more have been met with, but this should not prevent an attempt to free the lung in any patient in whom it appears reasonably likely to succeed. The prognosis in chronic empyema of tuberculous origin is not good. Occasionally fibrous bands are found passing from the membrane into the lung; these should be divided without hesitation. Even inseparable adhesion between the lower lobe and the diaphragm may not hinder a satisfactory result. Fuller expansion may be obtained during the after-treatment and contact of the lung secured with the chest wall by the method of blowing water from one bottle to another by means of a tube. It is not necessary to stitch the lung to the costal pleura, although it has been done with success by some surgeons.

The communication from Mr. Spencer<sup>20</sup> on "decortication for traumatic empyema with complete collapse of the lung" is the only one on this subject which has been published in this country so far as I can ascertain. There are, however, references made to this operation in some of our own text-

books. Unfortunately, these are occasionally founded on a complete misconception of the pathology of the disease and a wrong estimate of the benefits which may be obtained from "decortication."

The question of the anaesthetic which should be used may cause some anxiety in these cases; probably every kind has been tried, including intraspinal injection, but in the following case, where the ultimate result has been so satisfactory, Dr. Z. Mennell kindly gave ether by the intratracheal method. The condition of the patient was satisfactory throughout the operation and respiration perfectly unembarrassed.

At the present time there are several empyemata in the beds under my care at St. Thomas's, in some of which it may be advisable to do decortication of the lungs. The following has proved conclusively the great benefits to be derived from it:

Captain —, aged 28, was admitted to St. Thomas's Home from France on April 23rd, 1915. He had received a perforating wound of the left side of the chest on March 10th during the fight at Neuve Chapelle. He could not be moved for some days, but an operation was done at the base hospital on March 24th, the day after his arrival there, when a portion of rib was excised and a tube put in. "So much pus came away that the quantity could not be measured." On admission to St. Thomas's he was using a drainage-tube which passed through an opening in the sixth rib in the mid-axillary line, and from this there was a profuse purulent discharge. Above the spine of the left scapula there was a sinus with granulating opening which led to a comminuted fracture of the underlying ribs. Both wounds were septic, and he was thin and anaemic, had a rapid pulse, with a temperature which was always higher in the evening (99°–101° F.). He complained of considerable pain in the side, especially at night, and it was necessary to give morphine to relieve this. There was also a paroxysmal cough with much frothy expectoration.

His general condition improved enormously during the next few weeks, and the morphine was gradually discontinued. Attempts were made to leave out the large tube as the quantity of discharge diminished, but they were not successful. There were no signs of expansion of the lung. The breath sounds were absent excepting quite at the apex, and the whole of the left chest was in a condition of pyopneumothorax. As this appeared to be stationary and the general state was much improved, on the advice of Dr. Hector Mackenzie the chest was explored with the view of doing decortication of the lung.

On May 21st, a month after admission, a large oblong flap was made, parts of the fourth, fifth, sixth, and seventh ribs removed above the sinus, and the thoracic cavity quickly opened up. The lung was covered with a thick greyish-yellow, wash-leather membrane which prevented expansion and fastened it down to the posterior and inner part of the space. The cavity extended upwards in the direction of the apex and was apparently limited only by the dome of the pleura. A strip of this dense membrane was now separated with difficulty from the surface of the lung, beginning at a point as high as possible, to the lower limit of the cavity, and from the raw surface thus made the membrane was peeled forwards and backwards. The lung quickly began to expand, and by the time the process of stripping was completed was almost in apposition with the chest wall, in the position of full inspiration. The bleeding was slight. No attempt was made to peel off membrane from the costal pleura or diaphragm. A tube was placed in the lower part of the cavity and the flap sutured in position with catgut after all debris had been washed away with sterilised saline.

There was considerable shock after the operation, but the patient rallied well. For the next few days the chief menace came from attempts at oedema of the right lung, giving rise to dyspnæic attacks associated with a frothy exudate which was profusely expectorated. Relief was almost immediate after the exhibition of atropine hypodermically.

The recovery was somewhat slow, as it was a long time before it was possible to give up the use of the drainage-tube, various attempts to do so being unsuccessful on account of a re-accumulation of discharge. Towards the end of September it was found possible to omit it, and by Nov. 22nd, 1915, he was able to leave for the seaside with the wound closed.

Bacteriological examination showed that the *Streptococcus pyogenes* was the chief organism at work, but there were several others, and it was not considered possible to make a vaccine which would have been of use before operation.

Dr. Hector Mackenzie kindly examined this patient on Jan. 9th, 1917, and has reported as follows: "There was good resonance and vocal fremitus, and the breath sounds were well heard over the whole of the left lung down to the base. The left lung appeared to be expanded and to be acting efficiently. The general condition was very satisfactory." *Continued at foot of next column.*

## REPAIR OF LARGE BONY DEFECTS IN THE SKULL BY MEANS OF A METAL PLATE,

WITH A RECORD OF THREE CASES.

BY C. NOON F.R.C.S. ENG.,

MAJOR, R.A.M.C.; CHIEF RESIDENT SURGEON, THE NORFOLK WAR HOSPITAL.

In the large majority of cases in which there has been loss of substance of the bony parts of the skull, either from trephining or direct injury, there is no need of any operation to repair the bony defect. When only a small piece of bone has been removed by trephining, the edges of the trephine wound will become rounded off and smooth, and the hole in the skull will become filled with dense fibrous tissue, so that after a lapse of six months the defect will be hardly palpable. There are, however, a certain number of cases in which some operation for repair of the extensive damage done should be undertaken. Different methods have been described. Maget has recorded cases of restoration of cranial substance by insertion of an osteoplastic flap out from the external table of the skull in the vicinity. Morestin has described the use of cartilaginous transplants, while Ester has related a series of cases in which he repaired the skull after trephining by means of gold plates. The recorded cases would suggest that the method of repair by means of a plate is satisfactory, simple, and easy.

### *Indication and Contra-indication for Operation.*

There has been considerable discussion as to whether defects in the skull should be closed, but most surgeons would probably now agree that, briefly stated, the indications that some operation should be done are as follows:—

The hole in the skull, if large, should be closed for the sake of freeing the patient from the dangers to which he is subjected by having the brain insufficiently protected, and because the bones of the skull regenerate scarcely at all.

The mental condition of many patients with head wounds is often markedly affected. It is important before doing any plastic operation to observe the patient carefully and to be satisfied that his mental state is good. The best results in these cases will be obtained by operating on patients who are anxious to have "the hole" in the head closed. Those on whom I have operated were all much troubled by the fact that they could feel a large gap in their skulls, and they were all very anxious to have it closed.

*Pain.*—There are two main types of pain from which these cases suffer—namely, headache and severe tenderness in the region of the scar. The headache varies much in severity; all the cases which were operated on complained of it, but it was not of a very severe type. All were improved by the operation. Tenderness over the scar was in one case so severe that the patient could not wear even a soft cap. The operation completely cured this in every case.

*Inability to sleep* is occasionally complained of. This was a prominent symptom in two of the cases operated upon. The operation improved both cases.

*Pulsation of the brain* over the trephined wound was complained of by all the patients operated on. Though not a severe symptom, it appeared somewhat to worry them. The operation cured this in every case.

The condition of the scalp is most important. The scalp wound must be absolutely healed before any operation can be considered. An unhealed scalp is an absolute contraindication to any operation.

#### Operation.

*Preparation.*—The whole head is shaved 36 hours, and again prepared 4 or 5 hours, before the operation. Morphia  $\frac{1}{2}$  grain and atropine  $\frac{1}{60}$  grain are given half an hour before the anaesthetic is administered.

*Operation.*—The head is supported on a sandbag or special rest at a convenient height. A large semilunar incision is made with its base below. The flap should be so arranged as to expose fully the previous trephine hole with a margin of about  $\frac{1}{4}$  inches of skull bone surrounding it. The incision at the margin of the wound divides all the layers of the scalp with the exception of the periosteum. The flap is then dissected up from the periosteum for about  $\frac{1}{2}$  inch at its margins. The periosteum is then divided, and the remainder of the flap consists of all the layers of the scalp, together with the periosteum. At the margin of the trephine hole a quantity of scar tissue will be encountered. It is usually possible to separate it by a series of cuts without any exposure of brain tissue, so that when the centre flap has been raised the trephine hole is exposed, "plugged" with dense fibrous tissue. During the process there is usually free bleeding from the edges of the wound, but a few tissue forceps applied to the edge of the flap are sufficient to stop this, and no tourniquet round the head is necessary. The edges of the flap are then covered with gauze and saline at  $118^{\circ}\text{F}$ . is poured over the wound to stop any general oozing. The edges of the periosteum are then raised from the bone, and the plate, suitably cut, is passed under it, and pressed down flat on the skull. It is fixed in position by a few catgut sutures, the skin is then sutured over the plate, and if necessary a drainage-tube is inserted at one corner of the wound. Dressings are applied with firm pressure. The tube is removed at the end of 48 hours, and the wound is not again disturbed until the tenth day, when the stitches are removed.

#### Notes of Cases.

**CASE 1.**—Gunshot wound of head; destruction of part of right parietal bone; repair by metal plate. Patient aged 24. R.F.A., was transferred to Norfolk War Hospital on April 11th, 1916, complaining of pulsating swelling on right side of head. He was admitted to 15th General Hospital at Alexandria on Feb. 8th, 1916, with injury of right side of head. He was found to be suffering from cerebral compression, giving rise to paralysis of left arm and leg. An operation was done, skull trephined, dura mater opened, and a quantity of blood-clot removed from the surface of brain. He had since suffered from severe headache, with pain and tenderness over wound. The headache was severe, often keeping him awake at night, and the pain and tenderness over the wound were such that he could not wear a cap without discomfort. The pulsating swelling on side of head had gradually decreased, and he had quite recovered from paralysis of left arm and leg. He had no fits, his memory was good, and his mental condition was unimpaired.

On admission to Norfolk War Hospital (April 11th) he was rather pale, but otherwise healthy-looking. Temperature  $98^{\circ}\text{F}$ ., pulse 80, respirations 20. Eyes—pupils equal and reacted to light. Tongue protruded straight; no facial palsy, all cranial nerves appeared normal; mental condition good. In region of right parietal bone was well-marked pulsation, both seen and felt. The operation wound was almost quite healed. On palpation skin over pulsating area was markedly tender; margins of trephine hole could be easily felt; no well-marked cerebral hernia. June 1st: Wound quite healed.

June 29th: Operation; hole in skull closed by silver plate. Wound healed by primary union. Patient was discharged from hospital much improved, all his symptoms having disappeared except occasional slight headaches. The plate in head could scarcely be felt, and gave rise to no trouble.

**CASE 2.**—Shrapnel wound of head; destruction of part of parietal bone; repair by metal plate. Private, aged 26, was wounded in head by piece of shrapnel in May, 1916. Soon after being wounded he was trephined at a casualty clearing station; piece of right parietal bone removed. Progress was satisfactory, and he was admitted to Norfolk War Hospital on May 15th. On admission his general condition was good. Temperature  $98^{\circ}\text{F}$ ., pulse 80, respirations 20. Memory for recent events poor. Did not complain of any headache. Cranial nerves appeared normal. No paralysis, but slight weakness of left leg.

Wound over right parietal region still required dressing; pulsation over this area seen and felt; no cerebral hernia. The wound healed well, and he was discharged to an auxiliary hospital on June 6th. When again seen on August 10th the head wound had quite healed; scar firm and not tender. He complained of severe headache and said the "hole" in the head worried him very much. His mental state appeared fair, his memory had improved.

August 26th: Operation; hole in skull closed by plate. Wound healed by primary union, but four days after operation he became somewhat depressed and refused food. His mental condition gave rise to some anxiety for about 14 days, but he gradually improved and left the hospital apparently quite well on Sept. 17th. The plate in the head could not be felt, and gave rise to no pain or inconvenience.

**CASE 3.**—Shrapnel wound of head; destruction of part of parietal bone; repair by metal plate. Private, aged 22, wounded in head about June 28th, 1916; was trephined two hours afterwards at a casualty clearing station, and piece of right parietal bone removed. On June 30th he was transferred to Calais, and on July 4th was admitted to the Norfolk War Hospital. On admission his condition was as follows: Temperature  $98^{\circ}\text{F}$ ., pulse 80, respirations 20. Mental condition good, cranial nerves normal. No paralysis. Wound over right parietal region; pulsation marked, but no cerebral hernia. His progress was satisfactory, the wound healed, and he was sent to an auxiliary hospital on July 31st. When seen again, on Sept. 4th, he complained of headache, pain in scar, and pulsation of brain troubled him, especially when he moved about. His mental condition was good. On Sept. 19th the hole in the skull was repaired by means of a plate; wound healed by primary union. At end of ten days he was able to get about again. He still complained of headache, but this gradually improved, and he was discharged from the hospital in December. The wound was quite healed and painless. The plate could not be felt and he was much improved by the operation.

## A CASE OF ACUTE OSTEOMYELITIS OF THE SPINE.

BY LESLIE PEARCE GOULD, M.CH. OXON.,  
F.R.C.S. ENG.,  
TEMPORARY SURGEON, ROYAL NAVY.

THE following case of acute osteomyelitis of the spine, recently in the Royal Naval Hospital, Plymouth, is recorded on account of its rarity and the interesting problem in diagnosis which it raised.

The patient, aged 21, schoolmaster R.N., went sick ashore on Sept. 23rd, 1916, complaining of "severe pain in the back and left loin." He stated that he had had a cold in the head about a week before, and that the pain, which he had at first treated as lumbago, had started two days before. He had otherwise been in good health, and had not had any injury. When first seen his temperature was  $103^{\circ}\text{F}$ ., and he looked ill. No physical signs were found to explain the pain, and as the symptoms were not relieved by simple remedies he was admitted to hospital on Sept. 25th, under the care of Fleet-Surgeon R. St. G. Bond, R.N.

On admission his temperature was  $102^{\circ}$ , pulse 102, respiration 32. His skin was dry and flushed, his tongue very dry and beefy-red, and his general appearance suggested a severe toxæmia. He complained of constant pain in the small of the back, radiating round the loins to the umbilicus, the pain being more severe on the left side. There was tenderness to pressure over the upper end of the sacrum and the lower lumbar spinous processes, and the patient could not move freely or sit up, but there was no swelling or deformity of the back. The abdomen was somewhat distended and tympanitic. There was deep tenderness on both sides in the middle line in the umbilical region but no rigidity, and the abdomen moved freely with respiration. There were no abnormal signs in the chest. The urine was normal.

The condition remained much the same on the following two days, the temperature fluctuating between  $99^{\circ}$  and  $102^{\circ}$ , the pulse remaining rapid and the patient looking very ill. On Sept. 27th lumbar puncture was done and 3 oz. of thick creamy pus withdrawn from the spinal canal. From this *Staphylococcus aureus* was subsequently grown. There were no symptoms pointing to meningitis, and it was therefore thought probable that the pus was of extrathecal origin. The same afternoon some paresis of the legs, more marked in the left, developed, suggesting pressure on spinal roots. The knee-jerks were obtainable but weak, and plantar reflexes were flexor. In consultation with Surgeon-General G. R. Turner and Fleet-Surgeon Bond a provisional diagnosis of acute osteomyelitis of the spine was made, and laminectomy decided upon to relieve the pressure upon the cauda equina and to establish drainage.

**Operation.**—A median dorsal incision was made with the centre over the third lumbar spine. On separating the muscles from the left of the spines about 3 oz. of pus were evacuated; no bare bone could be felt by the finger and the pus appeared to be oozing out of a neural foramen. The third lumbar lamina was removed and similar pus at once welled out of the spinal canal. On mopping this away the theca was seen to be intact and pressed forwards against the posterior common ligament. No bare bone was found, and in the absence of any definite localising signs nothing further was done. A tube was inserted down to the spinal canal and the wound stitched up round it. The patient did not suffer shock, but there was no improvement in his condition the following day, except that the paresis of the legs was no longer present. In the evening his temperature reached 104°, his pulse rapidly became worse, and he died from heart failure on Sept. 29th. There were no symptoms of meningitis before death.

**Autopsy.**—On the same day an autopsy was performed. On stripping the psoas muscles from their origins pus was found oozing out of all the lumbar neural foramina into the muscles, where several small and separate pockets had formed. The pus had in addition tracked along the posterior primary divisions of the nerves into the lumbar muscles on each side. On opening the spinal canal pus was found on the posterior aspect of the theca extending from the last dorsal vertebra to the lower end of the sacrum; no extrathecal fat was visible, there was no leptomenigitis. The bodies of the vertebrae and the sacrum were minutely examined for an infective focus without success, but it is regretted that the laminae and transverse processes escaped a close examination owing to their being put aside and mislaid. All the thoracic and abdominal viscera were normal and no septic focus was discovered elsewhere in the body.

**Etiology.**—Acute osteomyelitis of the spinal column is fortunately a very rare disease, and in his exhaustive paper on the subject, written in 1911, P. Grisel<sup>1</sup> was only able to collect 85 recorded cases.

Like acute osteomyelitis of the long bones, it is essentially a disease of the growing skeleton, and—remembering that growth of the spinal column is not complete until the thirtieth year—it will be found that only one case (reported by Makins and Abbott<sup>2</sup> in a woman aged 46) does not fall into this category. The majority of cases occur during the second decade of life, and there are only 15 recorded in patients over 20. A history of injury in the form of a blow or a sprain of the back is forthcoming in about one-quarter of the total number, a fact which may explain the relative frequency of the disease in males rather than females (2 : 1); in a larger number there is some discoverable source of infection, very commonly furunculosis. The responsible organism is almost exclusively *Staphylococcus aureus*; *Staphylococcus albus* and *Streptococcus pyogenes* have been rarely found.

**Morbid anatomy and pathology.**—Any portion of the vertebral column may be affected, but the disease shows a preference for the lumbar vertebrae, which form its site in rather more than 50 per cent. of all cases. The cervical column comes next in frequency and the dorsal column last.

The infection may be limited to the body of a vertebra or to some part of the neural arch, and it may affect one vertebra only or several simultaneously. Further, it may take the form of a simple periostitis without massive necrosis, but more commonly occurs as an osteomyelitis with more or less extensive necrosis.

The gravity of the disease varies largely with its depth from the surface of the body; when the centrum alone is affected the mortality is as high as 60 per cent., while when the neural arch alone is affected it is as low as 25 per cent., and if it were not that in these latter cases the liability to an intraspinal spread is greater, the difference would be still more marked. The reason for this difference is purely an anatomical one. When the focus is in the body of a vertebra the pus usually collects in front of the vertebral column and forms a retropharyngeal, mediastinal, or psoas abscess, according to the level of the disease. When, on the other hand, the focus is in the neural arch the pus naturally tracks posteriorly and points in the back. It is clear that it there permits of earlier recognition and treatment. An acute retropharyngeal abscess may be recognised with equal promptitude, but a mediastinal and a psoas abscess necessarily remain undetected for a longer period, and indeed an acute psoas abscess has only once been opened during life. Not uncommonly an anterior and posterior abscess may develop simultaneously, and the cavities may then communicate with one another. Makins and Abbott<sup>2</sup> record two cases in which an abscess forming primarily in the psoas sheath tracked to the buttock, passing in the one case through the great sacro-sciatic foramen, and in the other over the crest of the ilium.

Of complications the intrathoracic are the most frequent—empyema, pneumonia, abscess in the lung. They may

arise by direct spread or by pyæmia. They call for little comment. Intraspinal abscess has been recorded in 31 out of 85 cases, and 21 of these proved fatal. In 12 cases the bony focus was in the bodies, and 11 were fatal. In 19 cases the focus was in the neural arch, with 10 deaths. It is a complication, therefore, which is far more grave where the focus is anterior to the cord. In origin the abscess is always extrathecal. It may be localised by adhesions and then has been known to cause a compression either of the cord or of the cauda equina, which in one case (Hunt<sup>3</sup>) was relieved by operation; but it is more usually diffuse: meningitis and meningo-myelitis may follow by lymphatic spread, without actual perforation of the meninges, and are always fatal. The only recorded cases of actual perforation of the meninges have resulted from operation (Lucas,<sup>4</sup> Rebizzi<sup>5</sup>). Cerebral abscess and cerebral meningitis have been known to occur by pyæmic invasion (Makins and Abbott,<sup>2</sup> Joel<sup>6</sup>).

**Symptomatology.**—Clinically, the cases fall into two groups.

In the first or fulminant form, fortunately the less common, the patient is taken suddenly and acutely ill with intense pain in the back, a rigor, high temperature, and all the signs of a grave intoxication, and dies within a few days before any local manifestations have appeared to permit of an accurate diagnosis. This group includes the more severe cases with the focus in the body of a vertebra, and the deep-seated abscess which forms is only recognised at autopsy.

The second and larger group presents a clinical picture which in its simplest form closely resembles that of osteomyelitis of the long bones. The onset is abrupt, with localised pain in the back, pyrexia, and the accompanying signs of an acute infection. On the first examination the affected part of the spine is found to be tender and rigid; the patient assumes the supine position and cannot move without severe pain, but there is no swelling of the back. After the lapse of a few days a swelling appears to one or both sides of the mid-line of the back. At first hard and brawny, with dilated veins upon its surface—a point on which Lannelongue<sup>7</sup> lays stress—the mass gradually softens and is recognised as a pointing abscess. The subsequent progress of the case varies with the gravity of the infection and the extent of the complications. Under favourable conditions a sequestrum is found loose at the bottom of the abscess and is removed, the severe symptoms subside, and the drained cavity slowly heals. In a large number of cases, however, the course is by no means so smooth. Symptoms arise which betray the existence of intraspinal suppuration or of the persistence of the infective process, and all too commonly the patient succumbs to meningo-myelitis or septicæmia.

**Diagnosis.**—The difficulties in diagnosis arise entirely in the early stages before the local signs of an abscess have developed, and are well illustrated by the case cited in this paper. The problem necessarily varies with the portion of the spine involved, but in every case the cardinal factor is the co-existence of (a) a grave toxæmia, and (b) persistent, localised pain, tenderness, and rigidity of the back.

The clinical picture may be said to resemble a condensed epitome of Pott's disease without deformity. Thus in the case reported there was first (a) localised pain over the lumbar spine, shortly followed by (b) girdle pains round both loins, and accompanied by (c) local tenderness, rigidity, and pain on movement, and finally followed by (d) the signs of compression of the cauda equina. It is by laying stress on the occurrence of some or all of these signs in association with the evidences of an acute infection that a diagnosis may be arrived at in the early stages. The appearance of an abscess may be delayed for several days, and although operative treatment, which alone offers hope of saving life, must be postponed until this decisive evidence appears, it is clearly of the greatest importance to recognise the disease at the earliest moment, in order not only to prevent the patient from being subjected to the consequences of a mistaken diagnosis, but also to concentrate the attention on the back, and ensure interference as soon as opportunity offers.

The possibility of locating an abscess in the muscles of the back by an exploring syringe at the first stages of induration must be borne in mind, for valuable time may be saved by acting before the abscess is pointing superficially. In the case reported the diagnosis was made as a result of a lumbar puncture undertaken in order to exclude meningitis; with one exception this is the only recorded case in which a diagnosis has been made in this way. The danger of infecting the meninges is so obvious that it cannot be recommended as a routine method of examination. At the same time, owing to the close connexion of the theca with the posterior common ligament, an extrathecal collection will tend to form behind and not in front of the cord, so that the risk is thereby minimised, and if there is clear

evidence that compression paraplegia has developed, lumbar puncture would seem to be a legitimate procedure.

**Differential diagnosis.**—The differential diagnosis necessarily varies with the part of the spinal column affected.

(a) When the focus is in the cervical column there is less chance of an error than elsewhere. A deep glandular abscess may be excluded by the fact that pressure on the vertex causes referred pain in the neck. Makins and Abbott also lay stress on the early widening of the neck from extensive oedema, a sign which points to the shutting up of a small quantity of pus deep in the neck. Meningitis may be excluded by the absence of mental changes and rigidity of the limbs.

(b) Occurring in the dorsal spine the disease has been taken for pneumonia, empyema, typhoid, and peritonitis. Either pneumonia or empyema may result from a forward extension of the abscess, and the mistake is therefore usually that of regarding them as the main disease rather than as complications. Enteric may be simulated when the vertebral bodies alone are affected and the patient rapidly lapses into a "typhoid state," the abscess being totally concealed. The early localisation of pain and the abrupt onset are the features which should focus attention on the spine. Enlargement of the spleen may occur in either case, and is therefore of no diagnostic significance. The confusion with peritonitis is referred to below.

(c) In the lumbar spine the disease has been mistaken for peritonitis, perinephric abscess, meningitis, and Landry's paralysis.

The confusion with peritonitis is due to the frequent occurrence of referred abdominal pain and of abdominal distension. The latter has been noted in several cases and has been variously attributed to the acute toxæmia and to involvement of the sympathetic chain in the abscess. But the mistake is one which should not occur if attention is paid to (i.) the character of the pain, its point of earliest onset and greatest intensity, and to (ii.) the relative mildness of the abdominal symptoms compared with the gravity of the general condition.

Perinephric abscess may be harder to exclude on account of the time that it may remain latent while causing grave symptoms. The points of difference are that perinephric abscess causes entirely unilateral symptoms, with the point of greatest pain and tenderness in the loin external to the erector spinae, while the symptoms of osteomyelitis are central or bilateral, and the abscess when it points comes to the surface either through or internal to the erector spinae, but not outside it.

Meningitis and Landry's paralysis are only likely to be considered in those cases in which there is a rapid intraspinal spread of suppuration, and it is then that a lumbar puncture may be used. If pus be found Landry's paralysis is excluded, and the presence of staphylococci should at once lead to the diagnosis of acute bone infection, which alone can cause a primary staphylococcal meningitis. The possibility of cerebro-spinal meningitis should be definitely excluded by the limitation of symptoms to the back, and by the absence of mental changes and other signs of involvement of the cerebral meninges.

**Treatment.**—Treatment consists in (a) finding and draining the abscess, and (b) as far as possible removing the bony focus. The actual operation required necessarily varies with the individual case.

1. The simplest and most frequent procedure consists in incising and draining a pointing abscess and removing any loose fragments of necrosed bone. This has been done in 41 recorded cases, and the statistics show, as might be expected, that it is most successful where the bony focus is in some part of the neural arch. Of the 41, 23 were of this category, and 22 recovered (84 per cent.). In 15 the focus was in the body of the vertebra, and only 7 recovered (47 per cent.). In some a part of a vertebra has been found loose in the cavity and has been removed at the time of the operation. In a few a subsequent operation has been necessary for the removal of a sequestrum. The operation may be regarded as the routine treatment for osteomyelitis of the neural arch.

2. More elaborate treatment has only been undertaken in 14 cases, where bone has been freely removed in order to drain an extrapleural or extradural abscess, or to remove an extensively diseased portion of a vertebra. The results have been encouraging, for 11 of these 14 cases recovered (78 per cent.), and it must be borne in mind that they were severe cases where the total mortality is high. Laminectomy has been reported seven times; for extradural suppuration, and in 5 cases (Hunt,<sup>3</sup> Donati,<sup>4</sup> Morian,<sup>5</sup> Riese<sup>10</sup>) has been successful. Costo-transversectomy has been successfully performed once to drain an extrapleural abscess (Israel<sup>11</sup>). In the present case it was certainly entirely unsuccessful in establishing free drainage, and arresting the course of the disease. But the autopsy showed that the failure was due to the wide diffusion of the pus into the

posterior muscles and round the theca, and the result is therefore a condemnation not of the operation but of the delay in operating. The figures quoted offer the hope that the present high mortality might be materially reduced if the disease could be recognised and treated at an earlier stage.

I am indebted to Deputy Surgeon-General V. G. Thorpe, R.N., and Fleet-Surgeon R. St. G. Bond, R.N., for permission to publish the case.

## THE CLOSURE OF COLOTOMY OPENINGS PERFORMED FOR WOUNDS OF THE RECTUM.

BY P. LOCKHART-MUMMERY, F.R.C.S. ENG.,

SENIOR SURGEON TO ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM, LONDON; HONORARY SURGEON TO KING EDWARD VII'S HOSPITAL FOR OFFICERS; SPECIAL CONSULTING SURGEON TO THE CITY OF LONDON AND FULHAM MILITARY HOSPITALS.

A TEMPORARY colotomy—that is to say, one which is not intended to be permanent—is a rare condition in civilian practice, and consequently the operation for closing such openings is not often performed. But with the commencement of the present war it was quite early recognised by those surgeons treating cases at the Front that bowel wounds involving the rectum or pelvic colon could only be treated satisfactorily by the immediate performance of a temporary colotomy, so as to deflect the faecal contents and enable the wound to be treated without faecal contamination. Quite a large number of such injuries treated by temporary colotomy are now to be found in the military hospitals; in one week alone I have personally seen three patients who have been sent over from the Front with temporary colotomies due to wounds involving the rectum. It is obvious that an operation for the closing of the colotomy opening will be necessary in all these cases before the patient can be said to have completely recovered from his wound or to be again fit for service, and there are probably very few of the cases in which this will not be possible. As a surgeon to St. Mark's Hospital I have probably had an exceptional experience of such cases, for I have frequently operated for the closure of a colotomy, and it seems to me that the present is a good time to place on record my experience, as it may prove of some value now that a number of such operations will have to be performed.

In my book, "Diseases of the Colon," published in 1910, several pages were devoted to this subject, but my experience since has led me somewhat to modify the views there expressed. It is unfortunate that the operation for closing a colotomy is by no means free from risk. The following table, which is taken from my book, shows the results in 36 cases collected from various sources previous to 1910:—

Opening closed successfully	...	...	...	...	...	16
First operation failed	...	...	...	...	...	9
Repeated operations failed	...	...	...	...	...	6
Patient died as the result of operation	...	...	...	...	...	5

It should, however, be stated at the present time, at any rate in the hands of good surgeons, the risk of failure is certainly not as great as these figures seem to show. In the last two years I have closed eight such openings at the first attempt without a failure. There are two methods available for closing a colotomy: (1) destruction of the spur with subsequent closure of the skin opening; and (2) immediate closure by resection and suture. Of these the first is the easier and by far the safer. The only objection to it is that the condition left is not quite normal, as the bowel remains attached to the abdominal wall and there is often a weak spot which may necessitate the wearing of a belt or support. The second method is attended with decided risks and should not be attempted by anyone who has not had experience of end-to-end anastomosis of the large bowel, but it has the advantage that anatomical restitution of the parts is secured. It is, of course,

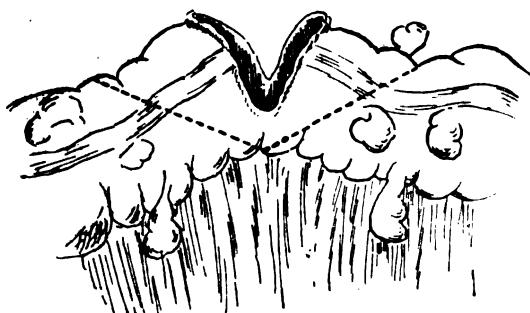

obvious that no attempt should be made to close the colotomy until the original wound in the rectum is quite soundly healed, and, in fact, it is wise to postpone the operation till all the wounds are healed, whether they communicate with the bowel or not.

#### First Method.

*By destruction of the spur.*—For this an enterotome is required. The two best forms of this instrument are one in which a male blade fits into a double female blade, the blades being made of thin steel and with a waved edge, and a second form with ribbed parallel blades in which one blade is provided with spikes which fit into holes in the opposing blade. The enterotome should be put on as follows: The first and second fingers of the surgeon's left hand are passed into the bowel, one finger in the upper and one in the lower opening, and are moved about until only the double thickness of bowel wall can be felt between the fingers. The enterotome, with the blades open, should then be passed into the bowel along the fingers with one blade in each portion of bowel, the fingers acting as guides. At least 3 to 3½ inches of the spur should be caught between the blades at the first application, and the blades should then be screwed firmly together to prevent any possibility of slipping. The spur must be completely divided for from 3 to 4 inches, rather more, in fact, than appears to be necessary. This is to allow for cicatricial contraction in the subsequent join. If possible the spur should be completely removed, so that no spur at all can be felt after the instrument is separated. This will certainly require more than one application of the enterotome. I have never known it to take less than two applications. The screw at the back end of the enterotome should be tightened up each day until it is as tight as it will go. The instrument generally causes a certain amount of pain during the first 24 hours for which, if necessary, morphia must be administered. It takes from four to five days for the instrument to become loose, and a day or two should then be allowed to elapse before applying the instrument to what is left of the spur. When the spur has been completely divided an operation should be done to close the external opening. The mucous membrane should be separated from the skin and muscles and inverted with catgut sutures, and the muscles and deep parts closed over it, also with catgut. As there is considerable risk of sepsis it is advisable to provide a drain. The drain, however, should not be placed through the original wound, but through a stab wound made 2 inches away from the primary wound. As a rule, by this method, which is comparatively safe and easy of application, primary union is secured. It will certainly fail, however, unless the spur is very thoroughly divided.

#### Second Method.

*By immediate resection.*—The two risks of this method are leakage from the line of union, which is necessarily inside the peritoneal cavity, and sepsis. It is obviously not easy

to be certain of sterilising the skin of the abdominal wall and the mucous membrane of the colotomy opening, and failure to secure this will result in peritonitis or sepsis in the wound. The bowels having been previously thoroughly cleared, the abdominal wall and the mucous membrane of the colotomy opening should be well iodined. The mucous membrane of the opening should then be carefully dissected out and closed with silk sutures. The wound should be dabbed over with iodine again and the instruments and gloves changed. The wound should then be deepened on one side until the peritoneal cavity is reached and opened. With one finger inside the abdomen the bowel should be separated from the skin all round with scissors and the loop

drawn well out of the abdominal cavity. The whole wound area should then be carefully packed off with towels or large swabs. No attempt should be made to stitch up the original opening in the colon, but the involved portion of colon should be cut out by a V-shaped resection, the apex of the V being towards the mesenteric attachment and the base containing the original opening (see illustration). It will generally not be necessary to cut through the bowel at the mesenteric attachment, but those portions opposite the mesenteric attachment should be freely cut away on both sides of the opening. It will be seen that the bowel is cut across very obliquely; this ensures a good and uniform blood-supply to the whole of the cut edge, which would not be the case if the bowel were cut transversely. It also ensures the lumen of the bowel at the point of union being, if anything, larger than the normal lumen, which compensates for any subsequent contraction of the line of suture. The two ends of the bowel are now accurately sewn together with catgut. The suture should be started on one side of the bowel and carried first across the mesenteric attachment to the opposite side and should take up all the coats. It finishes at the point where it began, and a peritoneal stitch is subsequently put over the first line of union in order to make all secure. The bowel is then dropped back into the abdominal cavity; the ragged hole in the abdominal wall, where the original hole was, is trimmed up and sewn together in layers. It is advisable to provide drainage either by means of a small tube or, better, by a piece of rubber tube an inch wide passed well down to the back of the abdomen on the outer side of the colon and drawn out through the lower end of the incision. This drain can be shortened on the second day, so that it only passes through the thickness of the abdominal wall. Drainage is necessary because *B. coli* infection in the neighbourhood of the anastomosis is very difficult to avoid with certainty, and if drainage has not been provided may cause very serious trouble. The colon bacillus is always present in large numbers in the sigmoid, whereas the small intestine contains few infective organisms; consequently drainage is not necessary when joining up the small bowel, but always advisable when dealing with the large bowel.

After this operation the bowels should be opened on the second day, either with a small enema or a dose of salts, and be kept acting daily. There is no advantage in locking up the bowels for a long time, and the dangers of subsequent trouble are much greater if the patient is once allowed to become constipated.

Hyde Park place, W.

## Clinical Notes: MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### A NOTE ON THE USE OF "BIPP" FOLLOWING THE OPERATION OF BONE-GRAFTING.

BY H. STEWART BRANDER, M.D. ABERD.,  
CAPTAIN, R.A.M.C.

Albee's admirable and fascinating book on bone-grafting will undoubtedly be of great service to surgeons at the present time. The technique of the operation of bone-grafting rendered necessary by the character of wounds caused by modern projectiles requires careful consideration owing to the fact that in these wounds cicatricial tissue is often extensive and the blood-supply consequently poor. Seeing that one must undermine the scar tissue in order to expose the ends of the bone to be grafted, and at the same time avoid the well-known risk of re-lighting infection in a wound which has been healed for months, I venture, in order that it may possibly be of help to some other surgeons, to record my experience with the use of "Bipp" following a bone-grafting operation. This I do because, in my opinion, the strictest aseptic precautions alone, are not always sufficient. The following is a history of the case:—

Corporal, R.A.M.C., aged 26 years, wounded by shrapnel at the Lancashire landing, Gallipoli, on July 11th, 1915. Transferred to a military hospital in this country on July 27th, 1915. Patient had a compound fracture of left radius. X-ray showed radius fractured in two places—viz., about junction of middle and upper thirds and at

junction of lower and middle thirds. From the history of the case it is evident that there was much purulent discharge from the wound due to necrosed bone. The sequestrum was removed on Oct. 13th, 1915, and the wound healed about eight weeks afterwards. Patient was discharged from the Army on June 8th, 1916, as medically unfit. As a Chelsea pensioner he applied for treatment at the War Hospital, Keighley, and was admitted under my care on Nov. 13th, 1916. On admission to this hospital there was a healed scar 4 in. by 2½ in. on the extero-anterior aspect of the left forearm. The scar was very adherent to underlying structures. There was marked wrist-drop and apparently considerable loss of muscular tissue. The proximal and distal ends of the radial fracture could be readily felt at about a distance of 2 inches from each other. This was also well seen in skiagram.

Employing strict aseptic precautions, I operated on Nov. 26th, 1916. I took the graft from the tibia and followed Albee's technique throughout, except that a Hey's saw was used instead of the motor-driven circular-saw used by him. A long, curved incision was made on the front of the forearm well away from the scar. This was completely undermined and found to be adherent to the fractured ends of the radius, most of the muscular tissue in the proximity of the fracture having been destroyed either at the time patient was wounded or had subsequently sloughed. On completion of the operation the forearm was put up on a splint midway between pronation and supination. At the end of a week I dressed the wound for the first time and found that, although the skin incision had healed by first intention, part of the original scar tissue about the size of a five-shilling piece had sloughed, exposing about an inch of the graft. My first impression was that the operation was doomed to failure. Employing very strict technique according to Rutherford Morison's method, however, I "Bipped" the sloughing surface and renewed the "Bipp" every ten days, with the result that the skin wound is now (nine weeks after operation) healed and the union of the graft to radius strong. Skiagram shows the graft in excellent position.

Having had excellent results with "Bipp" in compound comminuted fractures, hernia cerebri, &c., its use after this bone-grafting operation suggested itself to me. In this connexion I wish to take the opportunity of thanking Lieutenant-Colonel Sir Berkeley Moynihan for advising and encouraging me, on one of his official visits of inspection at this hospital, to persevere with "Bipp" in the treatment of troublesome comminuted fractures; also Colonel Robert Jones for the opportunity he gave me of seeing a bone-grafting operation at the Military Orthopaedic Hospital, London.

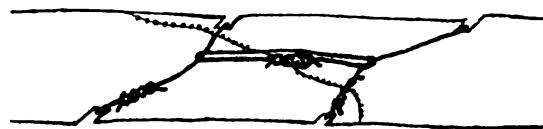

War Hospital, Keighley.

#### A NOTE ON THE SUTURING OF FRACTURED BONES BY ABSORBABLE LIGATURES.

BY KENELM H. DIGBY, M.B. LOND., F.R.C.S. ENG.,  
HO TUNG PROFESSOR OF CLINICAL SURGERY AND PROFESSOR OF ANATOMY, UNIVERSITY OF HONG-KONG.

THIS preliminary note refers to a method first worked out upon isolated bones which were specially broken for the purpose, and upon the broken limbs of cadavers. No one should attempt the method in a living patient until he has tested it for himself and practised the technique on dead bones (human or other animal). The union is not very strong, but it is claimed that, in conjunction with careful splintage, it will maintain the fragments in accurate apposition in selected cases.

The method may be illustrated by taking the instance of an oblique fracture of a long bone. After an incision has exposed the fracture two oblique cuts, at right angles to the

fracture line, are made on the surface of each fragment. These are easily made on the more exposed fragments by means of a hack-saw and on the deeper or more buried fragments by a Gigli's wire-saw. Two stout ligatures of chromicised catgut, guaranteed to resist absorption for at least 30 days are slipped into the grooves and knotted tightly. A third ligature uniting the two oblique ones is employed to tighten them still further (see diagram). It is absolutely essential that the ligatures be very tightly

drawn. For this reason the ends of the catgut must be clamped in artery forceps so that a maximum force can be used in tying the knots. The wound is then closed and the limb placed in appropriate splints.

The method has the following advantages over the use of plates and screws: (1) The operation is much more speedy and requires no special instruments; (2) no foreign body is left in the tissues such as may provoke an effusion of lymph, favouring the occurrence of sepsis, or, at a later period may set up rarefying osteitis and a permanent weakness.

#### NOTE ON THE USE OF PHYLACOGEN IN PUERPERAL SEPSIS.

BY J. H. REYNOLDS, M.B., C.M. EDIN.

THE following two cases may prove of interest to those who are so unfortunate as to run up against puerperal sepsis, and are not near enough to a laboratory to have a vaccine prepared, or cannot wait for it.

CASE 1.—Patient, aged 26, married, a strong healthy primipara. On Dec. 12th, 1913, she had been in labour some hours before I was called, and was disappointed in her nurse, but was satisfied to have the services of a friend whom I found sitting on the bed clad in a greasy old fur motor-coat. It subsequently transpired that she was waiting to go into hospital with a view to operation, the history suggesting tubal mischief. I at once borrowed the nurse from another case near by, who was perfectly satisfactory, and the confinement took place in a normal manner. Only two examinations were made, one on first seeing the patient, and the other after the liquor amnii was expelled. On the third day the pulse became more frequent, on the next the temperature started to rise, and intra-uterine douches of peroxide were given twice daily. In spite of these and other measures, the disease ran a severe course, and on the thirteenth day a clot was detached from the placental site during douching and lodged in the lower lobe of the left lung. She collapsed at once, and began to cough violently, later on bringing up bright blood and mucus. That decided me to try mixed infection phylacogen (P. D. and Co.), and I was able to inject some that afternoon. The symptoms improved with astonishing rapidity, and on the fourth day of the injections the patient was not only out of danger, but well on the way to recovery.

CASE 2.—Patient, aged 30, married, primipara. Five days before confinement, which occurred recently, her nurse brought her to me and called my attention to a mammary abscess. This was opened at once and swabbed out with chloroform. It healed before the confinement, which started with vomiting and weak pains which died away. Several small abscesses were noted on the buttocks and were painted with tr. iodi. After 24 hours the patient had a frequent and weak pulse, so she was given an injection of morphia and atropine which induced a few hours sleep; food could then be taken. The pains set in more vigorously but were not very strong, and as soon as the os was sufficiently dilated the membranes were ruptured, allowing the escape of a large amount of liquor amnii. Pains became more vigorous and the head reached the vulva, but after an hour so little progress was made that the child was delivered by forceps; its weight was 10½ lb. I had to wait three-quarters of an hour for the first pain after that, and expressed the placentae, as with the pain there was free haemorrhage. It came away entire. From the first day the temperature was elevated and well within 24 hours the lochia were offensive. Much the same treatment was followed out as in the previous case, but on the seventh day, as the temperature reached 102° F., I decided to use phylacogen again, and started injection on the following morning. After two injections all untoward symptoms ceased and on the third day the patient's condition was that of a woman who had a normal labour.

Of course, two swallows do not make a summer, but these are the only occasions on which I have needed phylacogen. The first case was losing ground till it was used, and the result was wonderful. In the second the patient, like the first, was a strong woman, but in this case I had the advantage of an excellent nurse. There is no doubt in my own mind that this was a case of primary inertia which passed into secondary. It is true that the symptoms were not nearly so severe, as she never had a rigor, although she felt very cold the day before I used the phylacogen. Still, the fact remains, as her chart shows, she made no real improvement till phylacogen was used, and I was nervous about her, because, rightly or wrongly, I looked upon the case as an infection before delivery—a condition I had never seen before.

## Medical Societies.

### HARVEIAN SOCIETY.

#### *Diagnosis in Dyspepsia.*

A MEETING of this society was held on March 1st, Dr. AMAND ROUTH being in the chair.

Dr. ROBERT HUTCHISON read a paper on Diagnosis in Dyspepsia. He defined dyspepsia as a disturbance of digestion caused by organic disease or functional disorder of the stomach. Owing to the widespread nervous connexions of the stomach and its close relations to other organs in the abdomen dyspepsia was prone to be simulated by disease elsewhere than in the stomach itself. Amongst such conditions, in which vomiting was chiefly the deceptive symptom, were pregnancy, uræmia, pulmonary tuberculosis, obstruction in the urinary passages (uro-kinetic dyspepsia) or colon, cerebral tumour, gastric crises of tabes, migraine, moveable kidney, nervous or hysterical vomiting, and, possibly, vicarious menstruation. Gastric pain might be simulated by gall-stones, angina pectoris and angina abdominalis, mucous colitis, and chronic appendicitis. Extra-abdominal causes had also to be thought of—e.g., pleurisy, spinal caries, myalgia, and herniae. Finally, air-swallowing (*eructatio nervosa*) was often mistaken for the flatulence of dyspepsia. Having eliminated the possibility of simulation, one had next to determine whether the symptoms were due to organic disease in the stomach or to perversion of its functions. If the patient complain of *severe* pain, or if there be much wasting, or if vomiting be a prominent symptom, the presumption was in favour of organic disease and of the necessity for surgical treatment. The organic diseases which have to be differentiated are: (1) ulcer, which is characterised especially by pain coming on at a definite interval after food; (2) carcinoma, in which pain is more constant and wasting and loss of appetite are prominent features; (3) stenosis of the pylorus and hour-glass stomach, in both of which vomiting is pronounced; and (4) gastritis. The differential diagnosis of these by symptoms, physical signs, and the use of special methods such as test-meals and X rays was considered in some detail. Midway between the organic diseases and functional disorders of the stomach were two conditions which partook to some extent of the character of both. These were: (1) the painful dyspepsia of young women, which is variously known as gastralgia, acute ulcer, gastric erosions, haemorrhagic gastralgia, and gastrostaxis; and (2) gastropostosis. The diagnostic features of these were described, and it was pointed out that they were not cases for surgical treatment. If simulation cases and cases of organic disease had been eliminated one might conclude that the case was one of functional dyspepsia. Further differentiation now depended upon the question of classification. Various classifications of functional dyspepsia had been suggested. One might adopt an etiological basis, dividing cases according to their supposed cause—e.g., (1) those due to physical causes, such as fatigue, unsuitable diet, defective chewing, and so on; (2) mental causes, such as over-work; and (3) moral causes, such as worry and depressing emotions. This classification, though unsatisfactory, was of some use in radical treatment. Or one might adopt a purely symptomatic division—e.g., into "flatulent," "acid," and other types. Such a basis, though often had recourse to, was apt to lead to unsatisfactory and rule-of-thumb therapeutics. The most scientific plan was to divide cases according to the nature of the disorder of function present. Now the physiological functions of the stomach are three: (1) secretory; (2) motor; (3) sensory; and any of these may theoretically be disordered in the direction either of excess or defect. Hence one got as secretory disorders hyperchlorhydria and achylia, as motor disorders atony and hypertony, and as (theoretical) sensory affections hyperesthesia and anaesthesia. These disorders might also occur in various combinations with one another, or along with organic disease. The differential diagnosis of these functional affections was then considered in detail.

## Reviews and Notices of Books.

#### *A Practice of Gynaecology.*

By HENRY JELLETT, M.D. Dub., F.R.C.P. Irel., Master, Rotunda Hospital, Dublin, &c. With 374 illustrations, many in colour, and 11 coloured plates. London: J. and A. Churchill. 1916. Pp. 618. Price 21s. net.

THE present volume represents the fourth edition of Dr. Jellett's "Short Practice of Gynaecology," which he has extended from a work written primarily for students and practitioners to one of a more advanced nature. The book has been considerably enlarged and altered in form and is a much more ambitious work than its predecessor. The text has been very largely rewritten and a large number of new illustrations added. Chapters on Radio-therapy in Gynaecology and on Vaccine Treatment in Gynaecology have been contributed respectively by Dr. Walter Stevenson and Dr. R. J. Rowlette. In view of the recent advances made in the use of X rays and radium in the treatment of various gynaecological affections the chapter on this subject is one of much interest. As Dr. Stevenson points out, the technique of the radio-therapy of deep structures has been developed to a large extent in the treatment of diseases of the uterus, and the results are such that there is a decided tendency to see if this treatment can replace the use of the knife in many gynaecological affections. He gives a clear and succinct account, free from technicalities, of the methods of using X rays, radium, and radium emanations in gynaecological cases. His description of the use of emanations is particularly interesting since this method is coming more and more into use. It has the great advantage of cheapness, emanations are supplied by an increasing number of institutions, and they can be collected in any shape or size of glass vessel suitable for the requirements of the case to be treated and without any risk of loss or permanent diminution of the value of the parent radium. The method of using emanation needles containing emanation glass capillaries, as devised by Professor Joly and the author, is described and strongly recommended; it certainly seems to have many advantages. The chapter on vaccines contributed by Dr. Rowlette contains a helpful account of this method of treatment in its relation to diseases of the pelvic organs.

The revision of the book and the choosing of new matter have been well done, and the whole forms a complete and good text-book which should be appreciated by students. In a further edition we think that the section dealing with "Atmocausis and Zestocausis" might well be omitted; these operations have never met with much favour, have been abandoned even by most of their former advocates, and if an action of this kind is desired it can be more safely and effectually obtained by the intra-uterine application of radium. The illustrations are good and a number of coloured plates have been included taken from Rudolf Jolly's "Atlas of Microscopic Diagnosis." It seems a pity that the author and publishers should have had to go abroad for these drawings.

Dr. Jellett has also written a simplified and shortened edition of the above book (*A Short Practice of Gynaecology for Medical Students*. 1917. Price 15s.). It is intended for the use of students by whom the larger book may be found too full. It has been shortened to 424 pages and contains only 316 illustrations and ten coloured plates, otherwise it is essentially the same book and requires no separate notice.

#### *Trattato dei Neoplasmi Maligni.*

Preceduto da uno Studio sulle Infezioni Chirurgiche in Generale. Di Professore D. B. RONCALI, Direttore del R. Istituto di Patologia speciale Chirurgica della R. Università di Padova. Volume Secondo. Con 133 figure nel testo e dieci tavole a colori. Torino: Unione Tipografico-Editrice Torinese. 1916. Pp. lxxix + 1040. L.34.

NEARLY six years ago we reviewed, at some length, the first volume of this work, which is now completed by the publication of the second volume. The story of malignant new growths is here treated on the same large scale to which attention was called in our review of Vol. I.; and the two volumes together form the most complete and exhaustive treatise in any language upon this very difficult subject.

This volume covers the fourth, fifth, and sixth parts of the whole work. These are : 4. Etiology of Malignant Growths. 5. Pathogenesis of Malignant Growth. 6. Therapy of Malignant Growths. Each of these subjects is dealt with very fully, and with careful criticism of all the work which has been done in relation to them from Hippocrates to 1914. Part 4 begins with an interesting account of the various views which were held as to the cause of cancer before the cell was discovered. The main part of this section is devoted to a very careful study of the various cellular theories which have been held, finishing with an account of the many parasitic theories which have been advanced since Nepveau's work in 1872.

The author, after obvious consideration, leans towards a parasitic cause; he thinks that there is a *quid vivum* of parasitic nature and foreign to the organism, and he shows in great detail that as in physiology ontogenesis is a recapitulation of phylogeny, so in pathology the genesis of cancer is a recapitulation of the genesis of inflammation. This section is the most difficult and also unsatisfactory on account of the disparity between the enormous amount of work which has been done on the etiology of cancer and the very small amount of exact knowledge we have concerning it. Part 5 deals with the predisposing causes of cancer and their modifications. Part 6 gives a very detailed account of the means at our disposal for alleviation of the symptoms, or possibly cure, of cancer. Under Therapy are included natural, prophylactic, palliative, symptomatic, and surgical therapy, and the account given is clear and quite free from prejudice. This section completes an enormous monograph, which is remarkable throughout for its accuracy of treatment, clearness and fairness, and which will be for many years valuable as the most complete résumé of our present theories and knowledge of cancer. Although the researches of the author have led him to believe in a parasitic theory of the origin of cancer, his statements and criticism of the work of others are fair and impartial, and he does not pretend to any finality in his views. He quotes the following from John Hunter in his preface : "Never ask me what I have said or what I have written ; but if you will ask me what my present opinions are, I will tell you." He has done so.

#### A Text-book of Pathology.

By W. G. MACCALLUM, Professor of Pathology in the College of Physicians and Surgeons, Columbia University, New York. London and Philadelphia : W. B. Saunders Company. 1916. Pp. 1085. Price 35s. net.

Professor MacCallum spoils an otherwise excellent book by the method in which he deals with his subject. Regarding the lesions of the human body as the different results of various forms of disturbance and injury, he divides his book into a series of chapters dealing with these different types of injury and describes various diseases as illustrations of them. The result is that a good many of the chapters contain a curious medley of subjects, such, for instance, as in Chapter XIV.—sero-fibrinous and fibrino-purulent pericarditis, pleuritis, peritonitis, appendicitis, endocarditis, lobular pneumonia, puerperal infection, pyæmia, &c.—a mixture which in a text-book becomes confusing. For a series of lectures and as a method of illustrating lectures Professor MacCallum's plan has many advantages, but it is not suitable to a text-book. As the author particularly states that the book is not intended as a book of reference, he somewhat disarms criticism. His work is, however, uneven. The subject of uræmia, for example, is dismissed in a paragraph of eight lines, and we are told that we are still in the dark concerning it. In view of the much greater emphasis given to the subject of nephritis, so cursory a treatment of uræmia is a mistake. There are much less important lesions which are treated at greater length. The paratyphoid infections are another case in point, this chapter being quite inadequate.

We do not agree with Professor MacCallum's conception of inflammation as a purely vascular phenomenon. His views on this subject are altogether too narrow, and his rigid separation of the phenomena of repair from those of inflammation is not in practice tenable. Nor does it seem correct to classify compensatory hypertrophy of a paired organ, such as the kidney, as an example of repair. The chapter on obstructions of the alimentary canal (Chapter XX.) is clumsy, again because of the author's rigid adhesion to

his method of presenting the subject. Such things as acute pancreatitis and gastric ulcer have to be dragged in as appendices in small print. The section on gastric ulcer is again inadequate, and we cannot agree that there is nothing specially characteristic about the several types of ulcer of the gastric wall.

There are 575 illustrations, many of them coloured, chiefly from drawings which are one and all excellent. We have seldom seen a better set of drawings in a text-book of pathology. They would be improved from the student's point of view if some indication of the extent of the magnification were added to the microscopical drawings. Fig. 16 is unfortunate as an illustration of intussusception associated with infarction of the intestine, for it illustrates multiple agonal or post-mortem intussusceptions in which infarction does not occur. Fig. 337 suffers from the wording of the legend which reads as though the collapse of the vertebrae causes the compression of the cord. The figure admirably illustrates the fact that it is the caseous material which causes the compression and not the bony displacement.

In the preface the author states that he has given references to literature which have been chosen so as to direct the student to readable and comprehensive papers which review the subject and give more complete references. The overwhelming preponderance of references to German literature in these lists makes them useless to the great majority of English students, at all events. Taken as a whole, however, the book is a good one, and can be recommended.

#### 1. Sanitation in War.

By Major P. S. LELEAN, C.B., R.A.M.C., Assistant Professor of Hygiene, Royal Army Medical College. Second edition. London : J. and A. Churchill. 1917. Pp. 336. Price 6s. net.

#### 2. Practical Sanitation.

By GEORGE REID, M.D. Aberd., D.P.H. Eighteenth edition. London : Charles Griffin and Co. 1916. Pp. 267. Price 6s. net.

1. THE second edition of Major Lelean's handbook has followed the first with a speed which does not justify the inveterate modesty of his preface. The "nomadic life of the service" may have prevented the author from pigeonholing his information in an office, but not from marshalling in his brain in orderly sequence all the essential facts of the great new system of sanitation which is one of the outstanding features of the Army Medical Service. The sanitary officer has turned his drawbacks into benefits, and has shown that intelligence and ingenuity brought to bear on bully-beef tins and petrol cans can result in a system of hygiene on a grand scale not always obtained by the expensive apparatus employed by our local authorities at home. The book itself has been carefully revised for the second impression, and the most notable addition is Chapter VIII., on Some New Departures in Field Sanitation, which is a collection of admirable pen-and-ink drawings with explanatory notes. Sanitation in peace, when it comes, will need to take notice of this monograph.

2. Dr. George Reid has seen 18 editions of his handbook for sanitary inspectors in the quarter of the century which has elapsed since he first published it. No recommendation is therefore necessary, but we may note that the book shows signs of careful revision. Some minor blemishes to which attention was called three years ago have been rectified.

#### JOURNALS AND MAGAZINES.

*The Annals of Tropical Medicine and Parasitology.* Vol. X., No. 4.—The first article in this number of the *Annals* is a report on the X ray examination of dysentery and other cases, by Captain C. Thurstan Holland, R.A.M.C. (T.). The author in his investigations followed the method of Glasson, described in his paper on the localisation of dysenteric ulcers by X rays, including the giving of large doses of bismuth subnitrate for at least six days beforehand. The results, however, showed nothing which might not equally well have been seen on plates taken in similar circumstances from persons not suffering from dysentery. Captain Thurstan Holland observes that "in ulcer of the stomach bismuth does not adhere to the raw surface of the ulcer, and the X ray diagnosis of gastric or duodenal ulcer cannot be made from this point of view" and he adds, "the question immediately suggests itself, Why, when it is proved

beyond any question that bismuth does not adhere to the surface of gastric or duodenal ulcers, should it adhere to ulcers in the lower bowel?" An interesting joint contribution comes next, supplied by Mr. A. Malins Smith and Mr. J. R. Mathews, on the intestinal protozoa of non-dysenteric cases. These observers, while working at the Liverpool School of Tropical Medicine on the protozoa of patients suffering from dysentery, had opportunities of examining, for the presence of protozoa, 250 patients who had entered hospital with illnesses other than dysentery. Of these 75, or 30 per cent., had protozoal infections; 20 had *Entamoeba histolytica*, either alone or along with one or more other infections; 48 had *E. coli*; 20 *Giardia (Lamblia) intestinalis*; 5 *Chilomastix (Tetramitus) mesnili*; and 4 *Trichomonas hominis*. It is, the authors say, significant that 8 per cent. of a mixed population of non-dysenteric cases should be carriers of *E. histolytica*; and it is still more significant when it is considered that more than half of the 250 patients examined had never been out of strictly temperate regions and therefore presumably had not been exposed to the infection of amoebic dysentery, or only exposed in the very smallest degree. Of the 250 patients 123 had been in tropical or subtropical countries. If only those are considered who had been in districts where *E. histolytica* was prevalent, the percentage of carriers of amoebic dysentery among them was 15.4. That this high percentage of positive cases should exist among those who had been exposed to infection and who were not suffering from dysentery is perhaps the most striking result of their investigations. Of the 20 patients who had *E. histolytica* in their stools, 3 had a history of dysentery, while 17 had no such history; these latter are what is termed "contact carriers." The authors believe that no such large number of contact carriers has previously been reported.—Mr. Henry F. Carter, lecturer on entomology in the Liverpool School of Tropical Medicine, contributes Some Remarks on the Spirochaetes occurring in the Faeces of Dysenteric Patients. Of 554 patients admitted to hospital for dysentery or related disease, 313, or 56.5 per cent., showed spirochaetes. He examined the stools of 100 other patients free from pathogenic amoebæ, 41 of whom were shown to be infected by spirochaetes. From these results he concludes that spirochaetal infections of the alimentary canal are almost, if not quite, as prevalent in non-dysenteric as in dysenteric cases.—A Preliminary Statement on the Treatment of Entamoeba Infections by "Alcresta Ipecac," is contributed conjointly by Professor J. W. W. Stephens and Dr. Doria L. Mackinnon, protozoologist to the First Western General Hospital, Liverpool. "Alcresta ipecac," it appears, is the trade name for an absorption compound of ipecacuanha alkaloids with hydrated aluminium silicate; it is made up in tablets, each containing 10 grains of "Rio ipecac," U.S.P. It is claimed that alcresta ipecac passes through the stomach unchanged and liberates alkaloids in the alkaline intestinal secretions, and that patients taking it suffer little, if at all, from the nausea and sickness that are so unpleasant a feature of some other forms of emetic treatment. The majority of the patients responded well to the treatment, and after being subjected to a pretty severe microscopical test were discharged from hospital as cured. The results on the whole compare favourably with those obtained by hypodermic injections of emetine hydrochloride.—The next paper is a first report on the protozoal findings in 910 cases of dysentery examined at the Liverpool School of Tropical Medicine from May to September, 1916, and is furnished jointly by four contributors—viz. Mr. H. F. Carter, Dr. Doria Mackinnon, Mr. J. R. Mathews, and Mr. Malins Smith. Of the 910 patients, 410, or 44.2 per cent., showed protozoal infections either alone or in mixed forms. 91 had *E. histolytica*, and 169 had *Giardia intestinalis*. The other infections noted included *E. coli*, *T. intestinalis*, and *C. mesnili*. The authors make a comparison of their results with those of previous investigators on the subject.—Dr. A. Breinl and Dr. H. Prie-tley, of the Australian Institute of Tropical Medicine, supply a Note on the "Arnhem Count" in Healthy Aboriginal Children of Northern Australia, in continuation of previous investigation. The authors believe that the results of the "Arnhem Counts" of Northern Australian native children living in a healthy district form a link in the proof that climatic changes in the tropics can be held responsible for the

altered blood conditions of inhabitants of the tropics, and that it is not necessary to resort to endemic disease as an explanatory factor.—This number completes Vol. X. of the *Annals*, of which a table of contents is appended, with an index of authors and also a general index.

The *North American Review* for January contains a very topical article by Mr. A. Lawrence Lowell, entitled "The Year and the World," attached to which are notes on the German peace proposals, on the violations of international law which have taken place in the course of the war, and on the future financial and commercial position of the United States and our own country. Further articles on the "Position of America in the Trade of the World," on "Italy's Relation to the War," on the "Food Situation in Austria-Hungary," and on the significance behind the construction and activity of the present British Government form a valuable commentary on important phases of the existing international position. A brief article, also by Mr. Lowell, entitled "A League to Enforce Peace," concludes with the following warning to the American people:—

There is no use in seeking to minimise the obligations that our nation would undertake; but no nation, and especially no rich and powerful nation, can be wholly isolated in the world to-day. If it stands alone, it must run a risk of collision, of a struggle with a dangerous antagonist, perhaps more than one enemy, and perhaps alone. Our people must seriously consider whether the security against war is not worth the cost of the insurance, and whether we should not be wise, whether we have not some duty, to take part in the policing of the world. Such an opportunity as will be presented at the close of this war is not likely to come again.

## Reports and Analytical Records FROM THE LANCET LABORATORY.

### VITAMOGEN.

(WILLIAMS AND CO., 24, HOLBORN, LONDON, E.C.)

We have already reported upon this preparation in our analytical columns, but we understand that it is now produced at a lower temperature with the object of securing an increased activity of the vitamins present. This is so far confirmed by our recent examination, since the preparation gave a very marked response for active enzymes. This shows that the temperature used in the course of preparation has been controlled at a point above which their activity is likely to suffer. Vitamogen yielded a small quantity of basic substance when extracted with 90 per cent. alcohol. The microscope showed the presence of pulse and cereal starches. The following analysis which we have made shows, apart from vitamins, that the preparation contains all classes of food substance: Moisture, 7.00 per cent.; mineral matter, 7.50 per cent. (equal to 2.50 per cent. phosphoric acid); protein, 24.96 per cent.; sugar, 20.83 per cent.; starch, 26.25 per cent.; fat, 1.51 per cent.; cellulose or fibre, 11.95 per cent. The preparation is largely soluble in cold water, the total soluble matters amounting to 62.80 per cent. The vitamins, of course, belong to a group of basic substances, but vitamogen also contains, as will be seen from the analysis, a rich proportion of phosphoric acid, derived partly from mineral salts and partly from organic phosphorus compounds.

### (1) ALBULACTIN; (2) CYSTOPURIN.

(THE BRITISH PURCHASERS OF THE SANATOGEN COMPANY,  
CHENIES-STREET, LONDON, W.C.)

Both these products are stated now to be British-made. According to our examination, they are, at all events, identical in composition with the products formerly reported upon in our columns—albulactin in THE LANCET of Jan. 7th, 1911, and cystopurin in THE LANCET of Oct. 11th, 1913. 1. Albulactin is a white, decidedly alkaline powder which swells into a gummy mass when treated with water. It represents the albumin of milk, which occurs in a larger proportion in human milk than in cows' milk, and the suggestion is that the addition of albulactin in cows' milk suitably treated has decided advantages in infant feeding, and a certain amount of evidence is brought forward on this point. On acidification albulactin does not produce a curd,

but a milky, uniform, finely divided deposit. Our analysis gave the following results: moisture, 12.80 per cent.; mineral matter, 3.20 per cent.; protein, 84.00 per cent. The preparation gives a much more marked reaction for sulphur than does casein, which serves to distinguish to some extent milk albumin from milk protein. 2. Cystopurin is a simple combination of hexamethylenetetramine with sodium acetate, which has been used in bacterial affections of the urinary tract. Apart from its antiseptic action, it also acts as a diuretic, while the presence of sodium acetate is calculated to induce an alkaline condition. There are differences of opinion as to whether hexamine should be administered under conditions favouring an acid urine or, on the other hand, an alkaline one.

#### AMBRINE.

(THE ANGLO-FRENCH DRUG CO., LIMITED, GAMAGE BUILDING, HOLBORN, LONDON, E.C.)

We have had an opportunity of examining ambrane, and it consists chiefly of paraffin wax, while it shows a small saponifiable value. The addition of oleum succini (oil of amber) is declared. The latter has some reputation as a local application in rheumatism. The main thing, however, in ambrane is the paraffin wax, which has been used considerably lately in the dressing of burns. This preparation is well adapted for the purpose owing to its purity and constant melting-point. It is supplied in the form of a cake of a light chocolate colour, which measures in length 6 inches and in width 4 inches, and about two-thirds of an inch thick. According to tests we have made, it has a melting-point of 122° F., which renders its application convenient. A full account of the use of ambrane in the Navy will be found in THE LANCET of Feb. 3rd, 1917, p. 201. Sir Arthur May, the Medical Director-General of the Navy, has arranged that every ship in the Navy, where burns are so frequent and serious a form of injury, shall be equipped with an outfit for their treatment by paraffin wax.

## THE CONTROL OF VENEREAL DISEASES.

### *War, Venereal Disease, and Workers' Insurance in Germany.*

Dr. Kaufmann,<sup>1</sup> President of the German Government Insurance Department (Reichsversicherungsaamt), has collected the experiences of the past years, including the first period of the war, gained by the German empire in its dealings with venereal disease and insurance. The campaign against venereal disease in Germany has been so speeded up by the emergencies of the war that, brief as is the period with which this book deals, an immense amount of work done, and of schemes for the future after the war, come under consideration. Dr. Kaufmann gives some interesting figures. For the past 20 years the frequency of venereal disease in the German army has shown a steady decline, which continued even during the first year of the war. In this year the incidence of venereal disease was only 14.4 per 1000, as compared with 137 in 1895. It seems to have come as a surprise to the Germans that their armies in the fighting-line were less subject to venereal disease than the forces stationed within Germany's own frontiers. Indeed, the difference between the incidence of venereal disease in the armies at home and abroad seems to be remarkably great. Hence the necessity for that vigorous campaign against venereal disease throughout Germany inaugurated, apparently, by the temporary administrator of Belgium, von Bissing. Dr. Kaufmann describes the conduct of this campaign, the machinery and organisation of which are those of the Workers' Insurance. This organisation, which has done so much to suppress alcoholism and tuberculosis, has begun to establish dispensaries for the subjects of venereal disease, including not only the discharged soldier, but every insured person in Germany. The author touches on the delicate subject of specialist *versus* general practitioner in connexion with treatment, and emphasises the importance of expert treatment. He also discusses the problems associated with the quack, whose activities in tinkering with the disease and blackmailing its victims are notorious, notably in Southern Germany.

<sup>1</sup> Krieg, Geschlechtskrankheiten, und Arbeiterversicherung. (Published by F. Vahlen. Price M.2.)

### Council Schemes.

Dr. Charles Templeman, medical officer of health of Dundee, has drawn up a scheme for that city, suggesting co-operation with the neighbouring authorities. He proposes that the town council shall come to an arrangement with the laboratory at the infirmary or the University College, and use the out-patient department of the infirmary as the treatment centre. The infirmary directors were willing to provide eight beds at a weekly cost of 35s. per bed.—At Leicester special medical officers, male and female, have been appointed for the treatment centre at the out-patient department of the Royal Infirmary, with attendance two days a week. A local branch of the National Council for Combating Venereal Diseases has been formed, of which Dr. C. K. Millard, medical officer of health of Leicester, is one of the honorary secretaries.

### *Notification of Venereal Diseases.*

Writing on the campaign against venereal diseases in this country in the *Münch. med. Wochenschr.* of Jan. 11th Dr. A. Blaschko, who contributed a report to our Royal Commission on Venereal Diseases, states that in well-informed circles in Germany, as in England, compulsory notification is not considered an advisable measure at present. He mentions the drastic proposals of the Munich Medical Society,<sup>2</sup> only to condemn them, adding that they are in such flagrant contradiction with the experience of daily practice as to be certain to meet with opposition from those possessing practical knowledge.

### *Early Preventive Treatment.*

Mr. Stanley R. Tattersall, a ship's medical officer, writes:—

For some months past I have been issuing packages containing one tube of mercurial ointment and one of an organic silver preparation. The appreciation given to these packages has not been encouraging. The majority of men do not go ashore with the conscious intention of sexual indulgence, the desire being rather proportional to the amount of alcohol consumed. When sexual desire becomes urgent they have either forgotten about the package or are too lazy to use it. Even the exceptions do not show inclination to apply for the outfit, though this is issued gratuitously. The demand at Dr. Rentoul's price<sup>3</sup> of 5s. would be nil. Slot machines would, in the present state of public opinion, make their customers unpleasantly conspicuous. The best preventive is probably "information." Some time ago I lectured on venereal diseases to all men under my care. For seven months afterwards no case of the kind occurred on board.

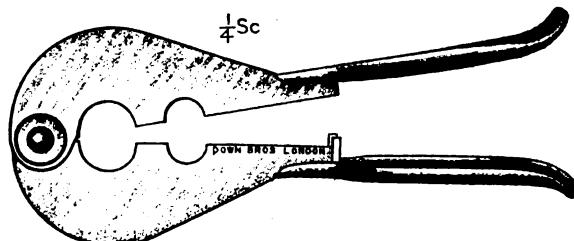

<sup>2</sup> THE LANCET, 1916, II., 1068.

<sup>3</sup> THE LANCET, Feb. 3rd.

## New Inventions.

### AN AMPUTATION RETRACTOR.

I DESIRE to bring to the notice of surgeons, and particularly those who may be handicapped by lack of assistance in the matter of amputations, a simple little instrument (see illustration) which obviates the necessity of a second pair of hands during any amputation. It is intended to hold back the flaps while cutting through bone, and to those who, like myself,

have been repeatedly called on during this war to perform amputations single-handed and with despatch, I feel sure the instrument will appeal, and once used will prove its value and indeed justify its right to a place in every properly equipped theatre.

The instrument has been made for me by Messrs. Down Bros., St. Thomas's-street, S.E.

COLLINGWOOD FENWICK, M.D.,  
late Surgeon-Major Armée Française.

# THE LANCET.

LONDON: SATURDAY, MARCH 10, 1917.

## The Mobilisation of the Medical Profession: the Position of Dentistry.

THE necessity of providing an adequate medical service for our ever-increasing armies still presses upon the professional committees whose duty it is to assist the War Office in this direction. It has been evident for some time that all the medical men who are prepared to take a temporary commission with alacrity, or who can accept such a commission without serious disregard of the pecuniary side of the matter, are already with the colours; the work of the Central Medical War Committee is growing very delicate, as the claims for exemption are seen more clearly to be based upon individual difficulty of circumstance or upon general shortage of medical men in the neighbourhood. As we state elsewhere, the Central Medical War Committee and the Committee of Reference of the English Royal Colleges have now selected their representatives for the Conference appointed at the instance of the Director-General of National Service, and it is generally expected in the medical profession that the deliberations which will ensue ought to settle promptly some of the difficulties which at present surround the mobilisation of the medical profession. Sir DONALD MACALISTER, who is to act as chairman of the Conference, will find himself in a position that will give full play to his genius for management.

It is possible that in the near future the same necessity for dealing economically with man power will arise with regard to the dental profession, as there is no question about the great importance of skilled dental aid in assisting to maintain the health of the community. We feel quite sure that the dental profession, if called upon, will freely and willingly adapt itself to any conditions which those in authority may consider necessary. The British Dental Association, with a view to the possibility of the mobilisation of dentists, has already taken steps to obtain all available information and statistics, which will be forthcoming when the call is made. The best manner in which to utilise the dentists will require careful consideration, for the number of qualified practitioners is strictly limited. Approximately there are 5000 dentists on the Register for a population of 40 millions. Of these about 2300 are of military age, and it is calculated that at the present time 1000 are serving the country either in the Royal Army Medical Corps, as dental surgeons to the Navy or Army, or as combatants. The number of dentists available for the civilian population is therefore some 4000, and if those of military age are called up, only 2700 will remain, a number

totally inadequate for the needs of the community. Before the war the harmful effect of dental disease on the public health was appreciated by the medical and dental professions, but the condition of the teeth of the soldiers has drawn public attention to the question and the nation is beginning to realise the value of healthy teeth. The importance, then, of an adequate supply of dentists for the needs of the nation must be kept clearly in view by the Government authorities.

How best can the supply of qualified dental surgeons be utilised? In the first place, it would seem advisable to create a Central Dental Committee to work in co-operation with the Central Medical War Committee. The dentists should be enrolled in a similar manner to that which has been adopted with medical men. Those of military age, if not required for the dental needs of the Army, should not be taken as combatants, but should be used for dental service as the fittest occasions arise. For instance, the manufacture of munitions has created large communities in districts previously but sparsely populated, and in such cases arrangements might be made for a supply of qualified men. The depletion of our dental hospitals of adequate staffs must be avoided, for these institutions are a public necessity, and already work has been curtailed owing to the shortage of students. In the case of dental practitioners, with some years of general hospital experience, more use should be made of their services in connexion with the treatment of gunshot injuries of the jaw and the diagnosis of cases where dental disease is suspected as a factor in the general condition.

## The Sphere and Future of Midwives.

AT a recent meeting of the Incorporated Midwives' Institute resolutions were passed upon matters affecting the employment of midwives of considerable interest to medical men. One of these resolutions contained an expression of strong opposition to the enforced notification of pregnancy as being likely to prevent the early engagement of a medical man or midwife to attend an expectant mother. Another resolution affirmed the belief that the midwife is the proper person to give antenatal care, because under the rules of the Central Midwives Board she is "responsible for the patient from the time of booking." The difficulty of providing effectively for antenatal care upon a large scale by employing exclusively for its administration the trained women who seek admission to the Midwives Roll at the hands of the Central Midwives Board was suggested by a third resolution, which contained a request that the Council of the Incorporated Midwives' Institute should endeavour "to discourage the depletion of the ranks of the midwifery profession, due to midwives taking up the less arduous and better paid work of health visitors." The same far-reaching resolution affirmed the desirability of educating public opinion as to the importance of adequate attendance at childbirth, "which can

only be attained by improving the status of the midwife and ensuring that she is sufficiently paid." To what source those responsible for this resolution were looking for an increase of the midwife's earnings was not revealed, and there may have been reason behind this reticence.

But if the introduction of infants into the world under conditions which will prevent wastage of life is to be attended with fewer elements of risk and less disappointing results, it is clear that the pecuniary side of the situation must be faced. At the present time the saving of infant lives has been rendered doubly valuable to the State by the occurrence of a devastating war, but the same cause has rendered the obtaining of money for public purposes more difficult than usual. Arrangements which might have been made whereby more adequate fees were received by medical men or midwives attending women in labour, and by those entrusted with their antenatal care, are now much more difficult to contemplate, and yet all public authorities would be well advised to consider them. The National Insurance Acts possess the necessary machinery through which the cost of the increased care of both mother and infant at the time of childbirth, and before and after the event, might be met, but the Commissioners cannot be expected to welcome any proposals for increased expenditure, and only the national nature of such a call upon their funds would be likely to move them. It would not be fair or reasonable, however, to subsidise the midwife, by the means suggested or by any other, to the exclusion of the medical practitioner. The fact that the working classes in many instances cannot pay adequate fees for attendance in childbirth affects medical men and midwives alike, and assistance in the one instance and not in the other would be unjust, though this is a view which the public will not necessarily appreciate. And here with regard to the education of public opinion a point suggests itself as worthy of consideration. The reports of the deliberations of the Central Midwives Board, which we publish from time to time, show that the Board has constantly to summon before it for disciplinary purposes women who have failed to obey its regulations in matters affecting the safety of their patients. The majority of these cases, it may be noted, fall under three headings: either the midwives have failed to recognise symptoms, or they have not advised that a medical man should be called in, or they have neglected prescribed precautions of cleanliness. In what proportion do these things apply to the two classes of midwives now practising—i.e., to those who were admitted to registration because they were practising before the Act came into force, or to those who have since been admitted after passing the tests of training and capacity which the Central Midwives Board imposes? In a recent pamphlet published by the Women's Industrial Council Miss J. F. MACKINTOSH states that during the past year of 102 penal cases in only 32 were the midwives certified, and of the 62 women removed from the Roll "far the larger proportion" were practising before the passage of the Midwives Act.

In a lecture recently delivered at the Royal Institute of Public Health on the rôle of the midwife and the protection of motherhood, the lecturer, Lady BARRETT, M.D., referred to the unsettled relationship, in their respective spheres of influence, of the midwife and the trained health worker; through a want of clear definition of their individual duties some misunderstanding has unfortunately arisen between these two indispensable classes of women. The midwife, owing to her long and undisputed jurisdiction over the destinies of the new-born baby, not unnaturally resents any suspected interference with her prerogatives. On the other hand, many of the highly trained and enthusiastic women who have been appointed as health visitors, and attached to the Public Health Service, may have gone beyond their legitimate provinces in repairing what they have considered the loss of golden opportunity on the part of the midwives. There can be no doubt that neither doctors nor midwives have sufficiently taken into account in the past the vast importance of prophylactic measures in the care of the pregnant woman. Lady BARRETT pointed out that the work of midwives and health visitors is for the most part distinct; it may overlap occasionally when the resulting difficulties must be overcome by tact and a little give-and-take on each side. The midwife, she said, should not resent the visits of a health visitor to the home during pregnancy any more than should a doctor, and the same tolerance should be extended to visits after the midwife has given up the case. A wise health visitor will not give advice to a mother regarding her personal health when the mother is already in the professional hands of a doctor and in receipt of those ministrations that according to the Act are expected from a qualified midwife. She can well occupy herself with matters of sanitation, housing conditions, and social economy. For the moment there appears to be some real difficulty in arranging the special niches which the health visitors and the midwives are to fill in those extremely useful institutions called antenatal clinics. In these there is undoubtedly work for both, but without whole-hearted co-operation between all concerned, including the parents, they cannot fulfil their possibilities for good. The future of the calling of the midwife requires close attention; it is endangered not only by some factors which the midwives can themselves control, but by others where they require the sympathetic assistance of the public, the medical profession, and welfare workers.

ROYAL SOCIETY OF MEDICINE.—At the Section of Electro-Therapeutics on Friday, March 16th, at 8.30 P.M., an address will be given by Professor W. M. Bayliss, F.R.S., on "The Origin of the Electric Currents Led Off from the Human Body."

ARMENIAN RED CROSS AND REFUGEE FUND.—The second annual report of this fund shows a record of useful work. During the year 1916 £4146 was collected and £5000 spent in the relief of the Armenian sufferers from the war. In addition to the provision of food, clothing, and medical necessities, an orphéauge has been built at Alexandrapol, the expenses of which are 1000 roubles per month. The address of the honorary secretary is 35a, Elstam-road, Kensington, W., and the bankers are London and South-Western Bank, Holland Park branch.

## Annotations.

"Ne quid nimis."

### RECENT WORK ON CEREBRO-SPINAL FEVER.

In the recently published fasciculus of the *Times History of the War*,<sup>1</sup> among other subjects dealt with is the epidemic of cerebro-spinal fever which early in 1915 gravely threatened the troops in training throughout the British Isles. The latest account states that in January, 1915, the Director-General of the Army Medical Services invited the Medical Research Committee to come to his assistance, and that immediately after this a plan of campaign was drawn up. This account is not quite accurate, for it ignores the valuable work that was done by Colonel W. H. Horrocks, C.B., A.M.S., Adviser on Sanitation to the Army Council, and by Surgeon-Colonel R. J. Reece, H.A.C., assistant medical officer to the Local Government Board, who from the time that cerebro-spinal fever was made compulsorily notifiable in September, 1912, had been watching the behaviour of the disease among the civil population. These two experts were asked by the Director-General to prepare a scheme for administering measures for the prevention and control of cerebro-spinal fever among the troops. For this purpose Surgeon-Colonel Reece was seconded by Sir Alfred Keogh from his regiment to devote his whole time to supervise the arrangements. A full account of this pioneer work was published in the *Journal of the Royal Army Medical Corps* in June, 1915. The scheme, which is still in operation, has proved very successful. The various Army Commands in England, Wales, Scotland, and Ireland were divided into suitable areas, in each of which a laboratory under a skilled bacteriologist was established, and, in addition, a special record-keeper was appointed in each area to make out lists of persons attacked and to obtain accurate information as to the sanitary environment, &c., in every case as it occurred. Both the district bacteriologists and the record-keepers made periodical reports to the War Office. At an early stage the newly established laboratories in England and Wales were inspected by Surgeon-Colonel Reece, who also at the same time instructed the district officers in their duties in connexion with cerebro-spinal fever. A part of the original scheme was the appointment of a skilled bacteriologist whose services would be available as a consultant, and to undertake research work, as the characters of the disease were not yet thoroughly known. The carrying out of this portion of the scheme was made possible by the Medical Research Committee agreeing to defray the cost of the consultant, who should give his whole time to the work. Dr. Mervyn Gordon, assistant pathologist to St. Bartholomew's Hospital, who had previously done admirable work in connexion with the bacteriology of cerebro-spinal fever for the Local Government Board, was appointed to the post, receiving the honorary rank of Major in the Royal Army Medical Corps. A central laboratory was established at the Royal Army Medical College, Millbank, and later, when the work had greatly increased, Dr. T. G. M. Hine was appointed assistant bacteriologist, with the honorary rank of Captain. The value of the services of these two expert bacteriologists has already been recognised by the Army Council, and Major Mervyn Gordon has been promoted to

honorary Lieutenant-Colonel and Captain Hine to honorary Major. In elucidating the various scientific problems associated with cerebro-spinal fever the Medical Research Committee had the co-operation, and assistance also, of several expert bacteriologists in various parts of Great Britain. The details of the bacteriological operations of the central laboratory are described correctly in the excellent narrative given in the *Times History of the War*.

### THE DIET OF THE BRAIN-WORKER.

THE amount of fuel required in the economy of the man whose employment entails bodily exercise in greater or less degree has been fully discussed during the last few months, but the brain-worker still remains in doubt as to the minimum intake of food which he requires. The text-books have so far contented themselves with pointing out that brain-work, of whatever grade of intensity, is associated with a scarcely measurable increase in metabolism. Professor W. M. Bayliss, in a course of lectures delivered last autumn at University College, London, and now forming the basis of a useful little manual,<sup>1</sup> comes to the rescue of the brain-worker and suggests that there is another consideration besides the actual quantity of energy developed by mental activity which should be taken into account. The oxygen consumed by any organ is an index of the food required by that organ. Experimental results prove that, although the actual consumption of oxygen in the nerve centres is not great, it has to be supplied at a high pressure. This is shown by the fact that even momentary stoppage of the food-supply causes immediate unconsciousness, although the oxygen of the blood still remaining in the brain cannot have been exhausted. Professor Bayliss suggests the analogy of an electro-magnet wound with thin wire which does not need much current to actuate it, but which, owing to the high resistance of the wire, requires a high voltage to drive the current through. It is, at any rate, possible that efficient mental work may require food to be presented at high pressure, and that a brain-worker should take a diet of energy value equivalent to that of moderate muscular work. The question deserves further consideration.

### TWO SIGNS OF THYROID ABSCESS.

THYROID abscess is usually considered a very rare condition. However, in the *Boston Medical and Surgical Journal* of Jan. 18th Dr. F. H. Lahey has reported three cases which he has seen within a few months among a large number of thyroid cases coming under his observation. He has also pointed out two signs which do not appear to have previously received attention—viz., limitation of chin elevation and depression of the chin on the sternum when swallowing. In two of the cases there was a history of tonsillitis and in the other the abscess appeared during recovery from bronchopneumonia. One case was sent to the hospital as a cyst of the thyroid, and had practically every appearance of that condition, as well as the two signs mentioned. In all the cases there was a tender swelling across the neck and corresponding, for the most part, to the outline of the thyroid gland. In one case there was some redness of the skin over the swelling. In the other two the skin was normal. There was fluctuation in all the cases,

although it was not easy to appreciate, as pus here is overlain by two sets of muscles. Dr. Lahey regards his two new signs as important in cases suspected of thyroid abscess. They are brought about by the action of the sterno-hyoid, sterno-thyroid, and omo-hyoid muscles on the abscess beneath them. The pain would result from tightening of these muscles. Tightening in swallowing would be prevented by depression of the chin upon the sternum. Elevation of the chin would stretch these muscles, causing pressure on the abscess and pain. Depression of the chin upon the chest is the natural position then for the patients to assume in swallowing. The treatment is simple—incision and drainage. It is important, however, to dissect carefully down to the gland, under local anaesthesia, and to cut the fibres of the sterno-hyoid transversely for a short distance on each side of the median line, as the longitudinal tension of the sterno-hyoid and sterno thyroid produces a tendency for any other incision to come together, thus interfering with drainage. On establishing drainage in these three cases recovery was rapid and uneventful.

#### THE TUBERCULOSIS PROBLEM.

IN his recent address at the Royal Institute of Public Health Dr. T. D. Lister dealt with the tuberculosis problem as it has been altered by conditions of war. It was desirable, he said, owing to the reduction in funds now available for what are called "complete schemes," to begin by stock-taking. He agreed with Dr. Maxwell Williamson, medical officer of health of Edinburgh, who recently stated that the whole method of tuberculosis treatment should be reversed, and the money at present spent on sanatoriums should be devoted to re-housing. As a result of his study of industrial tuberculosis, Dr. Lister had come to the conclusion, already expressed in our columns,<sup>1</sup> that the present campaign is wrongly based. The real aim should be to carry the lessons of the sanatorium into the workshop and the home. He condemned the policy laid down by the Departmental Committee as one of academic perfection, foredoomed to failure. Tuberculosis officers can be much better employed in visiting doctors than in visiting patients. The criticism and supplanting of the general practitioner that are now going on in this and other movements are a matter for regret. Dr. Lister spoke strongly, adding that one futility was being followed by another, and that the money available was being frittered away in collecting statistics for reports, instead of used to prevent the economic loss from consumption. This, he said, was the real national problem of the disease, and was known to be due to environment, the bacillus being a comparatively harmless pest to the majority of town-dwellers, who were becoming immunised. Sanarelli's views of the history of the disease in relation to industrial urbanisation were brought under review, and Dr. Lister said that all we were doing at present was to watch national immunisation overtake national infection in urbanised populations. He would place the treatment of tuberculosis entirely in the hands of the general practitioner, who should be encouraged and helped in urban areas to join in forming the staffs of properly equipped out-patient institutions for all classes of disease as well as tuberculosis.<sup>2</sup> But he held, of course, that the prevention of tuber-

closis was a matter for central administrative measures by the Local Government Board. In any area, he said, action should be taken if the deaths or notifications exceeded a figure to be called "the administrative index." This index would be a high multiple of the average incidence of mortality or of notifiable tuberculosis, a term requiring precise definition. By stating the administrative index high enough, only a few incursions of central authority would be necessary at first to destroy some of the worst hotbeds of the disease. Dr. Lister's suggestion is in effect an adaptation to chronic infection of the principles already adopted in the case, say, of a serious outbreak of typhoid or scarlet fever. It would, of course, take as many years to show its effects in tuberculosis as such methods take weeks in acute infections. But many other strongholds of disease would be affected by thus dealing with tuberculosis, the test disease of urban conditions, and both the factors of intensity of infection and of bad environment would equally come under consideration when the sole guide was an administrative index.

#### THE SUMMER TIME ACT.

THE Committee appointed by the Home Secretary to inquire into the social and economic results of the Summer Time Act of 1916 recommends the renewal of summer time for this year and in the future, the period suggested being from the second Sunday in April to the third Sunday in September. Most of the difficulties foreseen by the fearful in the application of the Act did not come to pass. The objection that hardship was involved for the very early riser on account of the reduction in his vitality in the early morning hours was submitted to the Health of Munition Workers Committee. The reply was that:—

The temperature of the human body is not constant, but is known to exhibit a distinct cycle during the 24 hours. A modification in the hours of work and rest leads to a corresponding modification in the hours of highest and lowest temperature. Thus, a party of Arctic explorers found that a complete reversal of their hours was followed within a few hours by a similar reversal of their temperature curves. The alleged curtailment of the hours of sleep for children has apparently been substantiated in certain districts, but the Committee concludes that on the whole the children benefited by summer time. The proposed earlier return to normal time in the autumn is a concession to the weaving sheds of Lancashire, in which the artificial light may raise the temperature unpleasantly in the earlier mornings of the second half of September.

#### INSANITY AND THE WAR.

THE annual report of the Royal Edinburgh Mental Hospital for the year 1916 contains some interesting remarks by the physician-superintendent, Dr. George M. Robertson, on the exceptional circumstances produced by the war and their bearing on mental institutions. For 1915 and 1916 the admissions attributable to alcohol were 7 per cent. and 7·7 per cent. respectively; the average annual percentage for the preceding seven years was 12·6 per cent. There can be no doubt, therefore, that alcoholic insanity has been decidedly less since the war began, and there is no statistical evidence in Dr. Robertson's hands that alcoholism as a cause of insanity has increased among women. It is true, of course, that increase of occasional drunkenness and of transient forms of mental disturbance of alcoholic origin may have occurred apart from the cases that come under the purview of the

<sup>1</sup> THE LANCET, 1910, II., 1122.

<sup>2</sup> THE LANCET, 1912, II., 1612.

asylum superintendent. Speaking generally, there are no signs of increase of insanity last year among the civil population. A decided fall in the number of females admitted under Dr. Robertson's care suggests that the effect of war work has been, so far, on the whole beneficial and less injurious than the semi-employed and shut-in lives that many women formerly led. Bereavement as an alleged cause of insanity has not proved itself in any way potent, probably because the blow is softened by psychological factors that can readily be imagined. A certain type of mind, however, is prone to seek consolation for its sorrows in the domain of so-called spiritualism, and Dr. Robertson sounds a wise note of warning in this connexion. He does not consider that those who are unversed in normal, and particularly in morbid, psychology are qualified investigators, and, least of all, that those who are wishing and longing for and unconsciously expecting certain manifestations from friends they may have lost make reliable observers. Accordingly, he regards the publication of "Raymond" at this time as much to be deplored. Such words from an eminent psychiatrist will, it is to be hoped, carry proportionate weight. Amateur and biased inquirers into the subject are, as a rule, quite unaware that "if they would meet those who are hearing messages from spirits every hour of the day, who are seeing forms, angelic and human, surrounding them that are invisible to ordinary persons, and who are receiving other manifestations of an equally 'occult' nature, they only require to go to a mental hospital to find them. It is true that the modern physician, by a long study of these phenomena, has come to regard them as symptoms of disease, and has renounced the doctrine of possession by spirits, though it had the double merit of simplicity and of antiquity to support it. If honest mediums do exist who hear inaudible messages, or feel communications without words, or see forms invisible to others, the mental physician accustomed to symptoms is inclined to regard their 'gifts' as being, if not morbid, at least closely related to the morbid, with no element of anything 'occult' about them."

Another annual report where the question of the war in its relation to insanity receives critical consideration is that of the Crichton Royal Institution at Dumfries. The physician-superintendent, Dr. C. C. Easterbrook, has analysed the histories of the 157 admissions of 1916, and in 19 (12 per cent.) a connexion between the two was apparent or traceable. Of these 19 patients two were women. In every one of the series the common factor of pre-existing nervous or mental instability was definitely determined to have been present. In other words, the influence of the war on these particular individuals has been to expose and accentuate their inherent weakness, whereas the normal individual is braced up and stimulated and his latent qualities of resistance are developed by the strain and stress of these times.

THE Lettsomian lectures of the Medical Society of London on "War Surgery of the Abdomen" will be delivered at 11, Chandos-street, Cavendish-square, London, W., on March 19th, 22nd, and 23rd, by Colonel Cuthbert Wallace, A.M.S. On April 2nd a discussion on "The Operative Treatment of Arterio-Venous Aneurysm," will be introduced by Colonel Charters Symonds, A.M.S., and Captain R. H. Jocelyn Swan. The time in each case is 8.30 P.M.

## NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

### Lahore Medical College.

THE annual presentation of prizes to the students of the Lahore Medical College and Medical School was made recently by the Hon. Colonel Harold Hendley, Inspector-General of Civil Hospitals, Punjab. The report stated that the new buildings with their up-to-date theatres and class-rooms were now available and all the discomforts and difficulties of the past had come to an end. 234 and 304 students are now on the rolls of the college and school respectively as compared with 176 and 269 in 1915. The total of 538 students exceeded that of the preceding year by nearly a hundred. 103 students had been refused admission to the school owing to want of accommodation. The only remedy suggested for this hardship is the separation of the school from the college, for if the former were re-established in another city it could be so expanded as to admit all students who apply.

### The Cultivation of Medicinal Plants in India.

At the last sitting of the Calcutta session of the Industries Commission Major A. T. Gage, I.M.S., Director of the Botanical Survey of India, gave expert evidence concerning the working of his department and the correlation of its activities with those of the economic botanists in the Forest and Agricultural Departments. He said that given the necessary staff and equipment it should be quite feasible to undertake the systematic cultivation in India of any or all of the species of drug-yielding plants and also the improvement of their quality. So far as he was aware no organised attempt had yet been made to discover what drugs were in demand in India and could be cultivated with advantage. At present there were 3000 acres actually under cinchona plantation in Bengal, and he saw great possibilities for an organisation devoted to the proper development of medicinal plants in India.

### Sub-Assistant Surgeons in Conference.

The eleventh annual conference of the All-India Sub-Assistant Surgeons' Association was recently held in Madras, and was attended by representatives from Bombay, Poona, Baroda, Ahmedabad, Indore, Gwalior, Agra, Meerut, Lucknow, Calcutta, and Burma, in addition to members from the Madras Presidency. Surgeon-General W. B. Bannerman, C.S.I., was in the chair. The chairman in his presidential address said that during his long years of service in India he had learned to respect and esteem the sub-assistant surgeon as a man who had, in most cases, gained his present honourable position by hard work in adverse circumstances and who could be relied upon to help in time of need.

### New Hospital for Rangoon.

At a recent meeting, presided over by the Lieutenant Governor, it was decided to take steps to collect funds for the erection of a new general hospital to be called the Lady Chelmsford Hospital.

### Vaccination in the United Provinces.

The prejudice against vaccination is breaking down, a fact which is indicated in the report of the Sanitary Commissioner for the United Provinces. The percentage of successful vaccinations in relation to the birth-rate shows a steady rise year after year, and last year reached nearly 72. A million and a half vaccinations were performed during that year, as against a million and a quarter during 1909-10. Concurrently with the increase in the number of persons vaccinated the mortality from small-pox has declined in the United Provinces to 0.05 per 1000 of the population from 0.38 in the previous year, and 0.13 in the quinquennial average.

### Overcrowding in Simla.

The question of the overcrowding of Simla forms the subject of some pointed remarks in the report of Colonel Hendley, officiating Sanitary Commissioner of the Punjab, which has just been published. Colonel Hendley considers that it may eventually be found necessary to limit the population of Simla by levying a heavy poll-tax and so making it difficult for persons not in employment to live there.

### A Gardening Corps for the Mesopotamian Field Force.

In order to meet the inadequacy of the present supply of fresh fruit, vegetables, and garden produce for the use of the Mesopotamian Field Force the Madras War Fund has offered

to raise and equip a number of units for gardening purposes, a unit being estimated as being able to cultivate 15 acres. The General Officer Commanding in India has accepted the offer of four such units which, with any further units organised, will form the Madras Gardeners Corps and be placed under the command of a European superintendent.

## MEDICINE AND THE LAW.

### *The Need for the Criminal Law Amendment Bill.*

CASES which it should be possible to deal with more effectually when the Criminal Law Amendment Bill is passed are at the present time of frequent occurrence. Mr. Francis recently sentenced a girl, pronounced by the police to be a disseminator of contagion, and of the worst personal character, to six months' imprisonment in default of finding a surety for her good behaviour, and declared that it was the only course open to him. He passed on the same day a like sentence on another girl of the same class, and heard "an unusually large number" of cases of soliciting soldiers. On the same day Mr. Chapman had before him nine women charged with soliciting soldiers in one locality alone (Waterloo Bridge-road), as well as two more from that district one of whom had two charges of procuring made against her. Presumably all these women would have been dealt with under the new law in its original form. Of the danger there can be no doubt. Whatever views may be held as to compulsory examination in any circumstances, the existence of the emergency cannot be disputed.

### *Adoptive Public Health Measures.*

The recently-issued report of the Local Government Board for Ireland contains instructive evidence of the limited amount of advantage to be derived from measures connected with the public health when they are made adoptive instead of compulsory. The notification of tuberculosis under the Tuberculosis Prevention (Ireland) Act, 1908, is stated to have made steady progress, and to extend to 79 sanitary districts. These, however, can only be described as containing "over a third" of the population of Ireland. Nevertheless, so far as the experiment has gone, it seems to be regarded as successful, some local bodies having passed resolutions in favour of its universal adoption. The Notification of Births Act, 1907, has now been made general by the Extension Act passed in 1915. Under the adoptive system Belfast county borough and Dublin county borough were the only two districts in Ireland in which the Act was put into operation. As it is observed in the report that infant mortality in urban districts in Ireland is considerable and "affords ample scope for a substantial reduction," the experiment now being tried upon a large scale should supply interesting results.

### *Criminal Lunatics and Broadmoor Asylum.*

In the House of Commons recently Mr. T. M. Healy, K.C., asked the Home Secretary a series of questions regarding the detention of Irish criminal lunatics. The reply elicited was to the effect that in several instances men charged with criminal offences out of Great Britain and found by the court to be insane are confined in an asylum in England, including at least one who was tried in Ireland, and that the authority for the practice was the Criminal Lunatic Asylum Act, 1860. It was added that the matter was one of convenience and that Broadmoor was a regular prison for the purpose. The statute referred to by Sir George Cave in his answer to Mr. Healy is known as the Broadmoor Act, as well as by the title quoted above. It enables the Crown to appoint any asylum or suitable place in England to be an asylum for criminal lunatics, but Broadmoor is the only asylum which has been so appointed. Under Section 2 of this Act a Secretary of State may direct to be conveyed to, and kept in, such an asylum any person for whose safe custody during its pleasure the Crown is authorised to give order, or any person coming within the terms of that section. Under other Acts (14 and 15 Vict., C. 81; 47 and 48 Vict., C. 31) criminal lunatics in India who are European British subjects, and criminal lunatics in other British possessions where they cannot conveniently be confined or suitably treated are removable to England, and may be committed to Broadmoor.

## THE SERVICES.

### ARMY MEDICAL SERVICES.

#### TERRITORIAL FORCE.

Lieut.-Col. A. M. McIntosh to be temporary Colonel whilst holding the appointment of Assistant Director of Medical Services.

### ROYAL ARMY MEDICAL CORPS.

L. C. Bruce (Captain, R.A.M.C., T.F.) to be temporary Major whilst employed at the Military War Hospital.

Capt. A. T. J. McCrea to be local Major whilst employed on embarkation duties.

A. de W. Snowden to be temporary honorary Major whilst serving with the British Red Cross Hospital, Netley.

To be temporary Captains: Temp. Lieuts. F. W. Lyle and R. C. L. Batchelor.

Temp. Hon. Major C. H. Miller, having ceased to be employed with the British Red Cross Hospital, Netley, relinquishes his commission.

Temp. Capt. F. G. Heard relinquishes his commission on account of ill health.

Temporary Lieutenants relinquishing their commissions: A. Neville, M. Jenkins.

### SPECIAL RESERVE OF OFFICERS.

Lieutenants to be Captains: B. J. Daunt, W. Saunderson, H. J. Wright, D. Columbos, W. E. Dickinson, H. T. Lamb, C. C. Harrison, F. B. Jago.

To be Lieutenants: F. C. A. Frith, F. Portas, J. R. Harris, C. W. Armstrong, and W. G. Verlaque (from University of London Contingent O.T.C.), M. W. H. Miles, M. Morrison.

### TERRITORIAL FORCE.

Major G. G. Turner is restored to the establishment.

Capt. (temp. Major) T. B. Wulstenholme to be acting Lieutenant-Colonel whilst commanding a Casualty Clearing Station.

Capt. L. C. Bruce is seconded whilst holding a temporary commission in the Royal Army Medical Corps.

### APPOINTMENTS IN THE INDIAN MEDICAL SERVICE.

It was recently announced that after the last open competitive examination for admission to the Indian Medical Service no similar examination would be held during the continuance of the war, but that such appointments as might be required to meet the absolutely indispensable needs of the Service would be made by nomination by the Secretary of State. To assist him in making these appointments, which, as already announced, will be limited in number to the absolutely indispensable needs of the Service. Mr. Chamberlain has appointed a Selection Committee who will summon and interview such applicants as may appear to be *prima facie* suitable and make recommendations for appointment. Applications for appointment should be addressed to the Secretary of the Military Department India Office, Whitehall, S.W., and should contain concise particulars of the applicant's medical degrees and career. Applicants must be over 21 and under 32 years of age at the time of application. Particulars regarding pay, promotion, &c., in the Service can be obtained from the Secretary, Military Department.

## URBAN VITAL STATISTICS.

(Week ended March 3rd, 1917.)

*English and Welsh Towns.*—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18,000,000 persons, the annual rate of mortality was equal to 18·4, against 22·5 and 21·0 per 1000 in the two preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 18·0, or 3·8 per 1000 less than that recorded in the previous week; in the remaining towns the rates ranged from 5·8 in Cambridge, 6·8 in Enfield, and 9·1 in Coventry, to 28·4 in Wigan, 29·6 in Bath, and 30·6 in Tynemouth. The principal epidemic diseases caused 350 deaths, which corresponded to an annual rate of 1·0 per 1000, and included 174 from measles, 51 from infantile diarrhoea, 47 from diphtheria, 43 from whooping-cough, 9 from scarlet fever, and 4 from enteric fever. The deaths from measles showed a further increase on the numbers in the five preceding weeks, and caused the highest annual rates of 4·2 in Wigan, 5·5 in Wimbledon, 5·8 in Ford, and 6·5 in Warrington. The 829 cases of scarlet fever and the 1436 cases of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 16 and 18 in excess of the numbers at the end of the previous week. Of the 6120 deaths from all causes in the 96 towns, 243 resulted from violence. The causes of 57 of the total deaths were uncertified, of which 12 were registered in Birmingham, 8 in Liverpool, and 6 in London.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death rate was equal to 17·9, against 20·1 and 19·6 per 1000 in the two preceding weeks. The 362 deaths in Glasgow corresponded to an annual rate of 16·9, against 18·0 per 1000 in London, and included 13 from whooping-cough, 2 each from measles, diphtheria, and infantile diarrhoea, and 1 from scarlet fever. The 136 deaths in Edinburgh were equal to a rate of 2·4 per 1000, and included 5 each from measles and whooping-cough, and 1 each from enteric fever and diphtheria.

*Irish Towns.*—The 195 deaths registered in Dublin were equal to an annual rate of 25·5, or 1·3 per 1000 below that recorded in the previous week, and included 7 from measles, 3 from infantile diarrhoea, and 1 from enteric fever. The 169 deaths in Belfast corresponded to an annual rate of 22·4 per 1000, and included 3 each from measles and infantile diarrhoea, 2 each from whooping-cough and diphtheria, and 1 from enteric fever.

THE King has appointed Mr. Alfred Murray Gray and Lieutenant-Colonel G. B. Stanistreet, R.A.M.C., Esquires of the Order of the Hospital of St. John of Jerusalem in England.

## Correspondence.

"Audi alteram partem."

### TUBERCULOSIS AND THE WAR.

To the Editor of THE LANCET.

SIR.—Referring to the portion of your leading article of Feb. 17th dealing with the tuberculous soldier, it appears that possibly the best solution is *in medio tutissimum ibis*. The suggestions of both Dr. T. D. Acland and Dr. E. H. R. Harries can be reconciled by keeping the tuberculous soldier still undischarged from the Army, and allowing him a few days' furlough with his family, before ordering him into a sanatorium. Men are very human, and it hardly savours humanity to condemn a man to three months' residence in a sanatorium, in his own district, after, say, a year in France, without allowing him a reasonable chance of seeing his relatives. The time thus occupied could be made use of by requiring his attendance at the dispensary, so that his class and treatment could be carefully considered, on behalf of the Insurance Committee. Quite a considerable number will be found not to require sanatorium treatment (Class 1), but would do better with light work, if permitted. In many instances light work of military character would be very beneficial to prevent the development of the loafing habit, which is so dangerous to the mentality of the early tuberculous case. Suitable cases (Class 2) would then be ordered into the sanatorium, with the requisite authority. Discipline, which is now our main difficulty, could thus be maintained. Then the tuberculosis officer could also be consulted on the question of pensions and allowances.

There are still left the hopeless cases of men who should have been under treatment long anterior, and who, ordinary humanity and British sense of justice demand, should be given decent conditions to terminate their lives, sacrificed in the interests of their country. The advanced cases are a distinct problem in finance. If they still remain in the Army the Insurance Committee would be reimbursed for their expenses, but not in a lump sum, as at present, for their passage may be protracted. The present procedure makes a contest between the economic and patriotic feelings of the Committee.

If these views are correct, all cases should be undischarged until their classification and treatment have been reported on by the tuberculosis officer, who is to have charge of the case, and pensions and allowances could then be apportioned by the Board, after being provided with his views, in accordance with the actual requirements of the case, the country's interest, and honour.

I am, Sir, yours faithfully,

H. A. ELLIS,

Tuberculosis Medical Officer, County Borough of Middlesbrough.  
March 2nd, 1917.

### A PLEA FOR THE EARLIER POST-OPERATIVE RAYING OF BREAST CANCER.

To the Editor of THE LANCET.

SIR.—It is unnecessary for me to advocate the raying of all cases of carcinoma, at least of the breast. Most surgeons send their hospital patients to the X-ray department so soon as the patient has regained strength sufficient to allow of her being moved. The system for which I now wish to put in a plea is merely the logical extension of this. "If it were done, when 'tis done, then 'twere well it were done quickly," and, I may add, the surgeon should make a point of seeing that it is done in all cases, and not leave this important, perhaps vital, matter to the discretion of an adviser who may, perhaps, have no knowledge on the subject.

The best time to administer the X-ray is undoubtedly at the operation. Then we can give two or more full skin doses without having to take the skin into consideration, but when I have proposed this course to surgeons I am met with the objection that it adds to the length of an operation already too lengthy. Whether this objection is a valid one I cannot say. Patients did very well after the operation

20 years ago, when I should say the average time taken was double what it now is, and in any case it is perhaps more the loss of blood than the length of operation which is detrimental.

I have recently had occasion to witness one or two operations for breast cancer, and as far as I am capable of judging, the present technique is perfect. Not much more progress can be made in shortening the operation, but as bleeding causes most of the delay, any improvement must take place in the method of checking this. I was much struck some years ago at the rapidity with which bleeding was checked by the use of the De Keating Hart air-cooled high-frequency current, called by him fulguration. I saw this employed in desperate cases of malignant disease, not for the purpose primarily of checking bleeding but for its reputed effect in preventing recurrence. I had also the opportunity of inspecting some of the patients who had been operated on at various periods, and I was struck by the suppleness of the scars and by the small amount of distortion caused, in spite of the large amount of tissue destroyed by the disease and removed at the operation. I was told by the surgeon that the fulguration did not delay but actually seemed to help healing. I did not see it used on closed wounds, however, and it might turn out detrimental to them. Here, it seems to me, is the direction in which to look for a means to shorten the operation for breast cancer, and the time saved by these means could be utilised to give the parts a thorough raying before the wound is closed. With the Coolidge tube two or three doses could be given in 15 minutes. This preliminary raying could then be followed up by a series begun as soon as the stitches are out.

It is true that excellent results are obtained in many cases of breast cancer now by operation alone, but the radiographer sees also many failures. If we and the surgeons could join our forces together more efficiently we might see still better results, and in any case there is no excuse for not trying.—I am, Sir, yours faithfully,

J. J. GRACE, F.R.C.S. Eng.,

Chief Assistant, X Ray Department, St. Bartholomew's Hospital, Welbeck-street, W., March 5th, 1917.

### SPIROCHÆTAL JAUNDICE.

To the Editor of THE LANCET.

SIR.—I have seen several letters regarding the nomenclature suggested to be given to the "spirochætosis icterohæmorrhagica" which has appeared at the various fronts of the belligerents in Europe. It appears to me that neither "spiroc. icterohæmorrhagica" nor "spirochætal jaundice" is quite appropriate. I would respectfully suggest that it be called "spirochætosis ictero-albuminurica," (1) because it has not yet been satisfactorily proved that the disease observed in Japan is the same as has been noticed in Europe. (2) or because "haemorrhage" is very rarely found in European cases, whilst "albuminuria" is, in fact, always present.

It appears to me also, not appropriate the name "spirochætal jaundice," because in Egypt, Indo-China, and the Arabian coasts of the Red Sea is endemic a relapsing fever with jaundice. The nomenclature I suggest, "spiroch. ictero-albuminurica," indicates the etiology, the two principal and constant symptoms, and the seat of the disease (*causa sedesque morbi*). I am, Sir, yours faithfully,

Rome, Feb. 28th, 1917.

Prof. UMBERTO GABBI.

### ECONOMY IN FEEDING.

To the Editor of THE LANCET.

SIR.—The medical profession is in a position to serve the imperial cause in a modest way by offering advice to patients in the matter of foodstuffs. A rigorous diet is twice blessed—it is patriotic and it encourages health, especially among the idle rich. Among persons of moderate estate it constitutes no mean agency in the encouragement of household economy. Among households visited by me in my daily work I find many persons eager to adopt suggestions which I have made in this matter. I recommend two meatless days in the week and a meatless luncheon every day. A luncheon dietary which I am told is strictly followed in many houses consists of oatmeal porridge, followed by salads or fruit. Many patients have told me that even after war is over they intend to follow the dietary suggested, since never before

meatless days and meatless luncheons were instituted in their household economy had they experienced better health, and never before had housekeeping money gone as far. Moreover, even without any persuasion, servants follow the example of economical living set by the heads of households.

I am, Sir, yours faithfully,

Streatham Hill, S.W., March 2nd, 1917. H. WALTER VERDON.

\* \* Servants cannot follow examples, however good, without detailed instructions, and these in too many instances cannot be forthcoming. Moreover, emergency instructions are not much good; the training ought to have preceded the existing situation.—ED. L.

## OFFICIAL MEDICINE AND THE THRIFTY SPIRIT.

To the Editor of THE LANCET.

SIR,—“I thank Thee that I am not as other men are.” These words sprang to my mind as I read the letter of your correspondent under the above title in your issue of Feb. 24th, and my heart burned within me to reply, but I felt sure that abler pens than mine would deal with the writer and forbore. Doubtless those who could answer have more precious work to do, or in the good old English way (*the mens concia recti*) feel that it would be undignified, but as many who read the unworthy libel may believe that silence implies a knowledge of guilt, I will venture to say a word.

There are three charges:

1. That the diners were guilty of unpatriotic waste. The answer is that the dinner was a simple, strictly “Devonport” meal, and that no one *could* have eaten more than he would have done at home. Is it more wasteful for 60 men to dine together than at 60 different tables? When communal meals are urged as a war economy it is rather silly to blame men for saving the expense of 60 separate dinners by agreeing to dine together. Those who shared it must have smiled bitterly at the charge of “feasting” and “overstepping the Controller’s food allowance.” I know I enjoyed my bread-and-cheese supper when I finished my day’s work at midnight!

2. That the honour to Sir Alfred Keogh should be postponed till after the war. The King thinks otherwise, and that it is well to cheer and encourage his soldiers and sailors during the war, and if ever a man deserved the encouragement of the approval of the profession he honours—*now*—it is the Director-General, whose work has been hindered and injured by the ignorant criticism of jealous enemies in high places and—with shame be it said—by the attacks of members of the medical profession.

3. That the Royal Society of Medicine is not doing its “bit” for the war. This last only accuses the accuser, for it proves that he has grossly neglected his duty as a Fellow, and knows nothing of the war activities of his *confrères*. Immediately on the declaration of war those responsible for the work of the society set themselves to consider what it could do to help, and it would scarcely be an exaggeration to say that almost the whole work of the society since then has been directly or indirectly war work.

You, Sir, could not allow the space were I to attempt to catalogue its war activities, but I know that not once but many times has it received the warm thanks of the War Office for its help, and that scarcely a day passes that letters and messages are not received from Whitehall. Does the writer of the attack know that the War Office at its own expense keeps a special telephone attendant at 1, Wimpole-street, and has installed a private telephone wire exclusively for war work? He is ignorant, too, of the abstracts, translations, reports, and even books and instruments which are being sent to medical officers at the various fronts, and have brought to the society heaves of grateful letters. I know something of these things, because I consider it my duty to know what any society with which I am connected is doing for the war, and if possible to help it. If your correspondent knows of anything useful the society could do, and is not doing, I am authorised to say his suggestions will be cordially received.

I am, Sir, in proud humility,

March 7th, 1917.

A PUBLICAN AND SINNER.

## Obituary.

### THE LATE PROFESSOR DÉJERINE.

FRENCH science has suffered a severe loss in the death of Professor Déjerine on Feb. 26th. Born at Geneva on August 3rd, 1849, of French parents, he studied medicine at the Paris hospitals, graduating in 1879 with a thesis on the nervous lesions of ascending paralysis. From this time on he devoted himself to the study of nervous diseases and their pathological anatomy. Chief of the clinic in 1879, he was elected to the hospital staff in 1882, becoming professor in 1901. Occupying in succession the chairs of history of medicine and clinical medicine, he found his proper place in the Salpêtrière clinic, where, after Raymond, he succeeded Charcot. His work marked distinct progress in the knowledge of nerves and of the central nervous system. He had as frequent collaborator Mme. Déjerine, née Klumpke, the first woman to hold the title of interne at the hospitals, and especially in the remarkable work, “Anatomie du Système Nerveux.” Of other important works, the “Traité des Maladies de la Moelle Épinière” was written in collaboration with Dr. Thomas, and a chapter, “Sémiologie du Système Nerveux” appeared in Bouchard’s “Text-book of Systematic Pathology.” Dr. Déjerine devised a method of examining the spinal cord in thin serial sections, which notably advanced the study of the pathological lesions of nervous tracts. His influence may be seen in the history of our knowledge of most nervous diseases—e.g., tabes, myelitis, radiculitis, aphasia. His great gifts were recognised during his life-time: in 1908 he was elected member of the Academy of Medicine, and he was an officer of the Légion d’Honneur.

LOUISA WOODCOCK, M.D., B.S. LOND., M.A. T.C.D., PHYSICIAN TO ENDELL-STREET MILITARY HOSPITAL, LONDON; PHYSICIAN TO OUT-PATIENTS, NEW HOSPITAL FOR WOMEN.

Dr. Louisa Woodcock, whose death on Feb. 17th in her fifty-second year we briefly recorded a fortnight ago, was educated at Cheltenham, where she studied classics, especially being attracted by the Greek language and literature. Passing on to Somerville College, Oxford, she took Honours Schools in morphology and zoology, spending a further year in the study of philosophy. In recognition of this work the University of Dublin awarded her the degree of M.A. From Oxford she entered the London (Royal Free Hospital) School of Medicine for Women, obtaining in 1900, after a six-years’ course, the degree of M.B. Lond. with honours in medicine and the M.D. in medicine four years later. At this hospital she held the Mabel Webb Research Scholarship in Pathology. After qualification Miss Woodcock took the first resident appointment opened to women at the Royal Free Hospital, that of house physician, and was then in succession pathologist and demonstrator of clinical pathology. At the New Hospital for Women, Euston-road, after holding resident posts, she became pathologist, and in 1907 physician to out-patients, and held the senior post at the time of her death.

In addition to these appointments Dr. Woodcock had a varied clinical experience which broadened her outlook and gave her a conscious security in her many fields of work. She was part-time assistant medical officer to the London County Council, doing special work on children’s eye-sight; she was medical officer to the Epileptic Colony at Chalfont

St. Peter, medical inspector to Bedford College, to the London Collegiate School for Girls and the Camden School for Girls, as well as medical officer under the Elementary School Teachers Act. She was also at one time Research Scholar at the London School of Economics.

When the war came yet other duties were added to a life already full to overflowing. Dr. Woodcock became treasurer to the Women's Hospital Corps from its inception in August, 1914, and did much organising work for the corps while it was at work both in Paris and at Wimereux. When the military hospital was opened at Endell-street she became physician, welcoming the opportunity of increased usefulness, but giving out energy more than she could afford, until the willing spirit could no longer dominate a constitution far from vigorous.

Dr. Woodcock's busy life and multitudinous duties gave her little time for writing, and apart from a report on melanoma of the eyelid (1903) and the recital of a case of glanders in THE LANCET (1906), her most important piece of work was to write, in association with Mrs. Sidney Webb, a report on the domiciliary treatment of the sick poor under the English Poor-law.

In social life Dr. Woodcock was regarded by many as very reserved, and so no doubt she was. One who knew her well ascribes this reserve in part to the result of temperament, in part to force of habit, and for the reason that, possessing so full a nature and a mind so well stored, she loved to be "at home" within, considering, ordering, planning—here, indeed, was her workshop. "But," he adds, "though reserved, Dr. Woodcock was capable of the closest and deepest friendship, and in its cause of a devotion and self-sacrifice which knew no bounds."

"As a physician, Dr. Woodcock found her true vocation. She was of the type which Peter Mere Latham used to delineate in his clinical lectures to the students at St. Bartholomew's Hospital about the middle of the nineteenth century; her science was supplemented by her art, both were warmed by a large humanity. On such lines she went her quiet ways, herself the mistress of her life. Perhaps the justest measure of our success in life will be found in the extent to which, individually, we are minded in the sense of loss which we leave behind. Judged thus, Miss Woodcock's success has been, without doubt, a great achievement."

HORACE BENGE DOBELL, M.D. ST. AND., M.R.C.P.LOND., CONSULTING PHYSICIAN, ROYAL HOSPITAL FOR DISEASES OF THE CHEST, LONDON.

THE death of Dr. Horace Dobell, on Feb. 22nd, at Parkstone Heights, Dorset, in his ninetieth year, removes a figure well known in London medical circles in the "seventies."

Horace Benge Dobell was the son of John Dobell, of Cheltenham, and after apprenticeship to a local surgeon entered St. Bartholomew's Hospital in 1845. Qualifying M.R.C.S. he commenced practice with a success which justified his removal to Harley-street in 1864. His attention was chiefly directed to diseases of the chest and pulmonary tuberculosis, and he was elected in 1858 to the staff of the Royal Hospital for Diseases of the Chest in City-road, becoming consulting physician in 1874. Leaving London in 1882 on account of his wife's health he settled at Bournemouth, where he practised as a consulting physician, R. L. Stevenson being among his patients at this time. In 1892 he retired from practice and built himself a house at Parkstone, over-looking Poole Harbour, where he lived until his death.

Dobell was a member of the old school before specialism developed, and while he aspired to be master of one part of his art he kept up his general knowledge. Extremely observant, his accuracy in diagnosis and skill in treatment were exceptional. Patient, sympathetic, and rapid, though never in a hurry, his patients became closely attached to him, and on his last birthday he received many letters of congratulation from those whom he had previously attended and from the children and even grand-children of old patients. He had seen the birth of modern medicine—when he went to St. Bartholomew's Hospital Paget possessed the only microscope there—and it was his hobby to follow its growth. From 1869 to 1877 he published a series of reports on the progress of medicine in different parts of the world. Earlier in his career the Royal Society had published his researches on the "Action of Light

on Animal Organisms," but the work was not continued. Long after retiring from practice he gave a sum of money to the Royal College of Physicians of London to endow lectures for research in bacteriology. His medical works include "Bacillary Consumption: its Nature and Treatment" (1889), "Diet and Regimen in Sickness and Health," of which the seventh edition appeared in 1882, and several others on various aspects of diseases of the chest. At the time of his death he was senior Member of the Royal College of Physicians of London and consulting physician to the Royal Albert Orphanage, Bagshot.

Dr. Dobell came of an artistic family. He was a fine artist himself, always illustrating his own books, and skilful in everything requiring manipulation, including music. In 1849 he married Elizabeth Mary Fordham, of Odsey House, Herts, who died in 1908. There were three daughters of the marriage, two of whom are living.

#### PETER HUGH MONTGOMERIE MACKELLAR, M.A., M.B., O.M. GLASG.

We announce with much regret the death on Feb. 20th, at the age of 72, of Dr. P. H. Montgomerie Mackellar, who was for many years a member of THE LANCET staff.

Dr. Mackellar was the son of Edward Hugh MacKellar and of Johanna Parkins MacKellar, daughter of Duncan Montgomerie of Buchanan. He received his education at the Loretto School, Musselburgh, Scotland, and entered Glasgow University, where he was a gold medallist, qualifying M.B. in 1866 and taking his M.A. degree in the same year and the C.M. five years later. After obtaining his medical qualification he entered the service of a shipping company as surgeon and made several voyages to South America, collecting specimens of the flora and fauna of the countries he visited and presenting them to his old teachers on his return home. Before leaving Scotland he held an appointment at the City of Glasgow Fever Hospital, afterwards becoming medical officer to the Joint Counties Asylum at Abergavenny. Coming to London, he was appointed assistant medical officer to the District Small-pox Hospital at Stockwell, and later medical officer at the Fever Hospital of the Asylums Board there. In 1873, on the occasion of an epidemic of relapsing fever, Dr. Mackellar made his first contribution to our columns in a careful description of the cases admitted to the hospital.

Dr. Mackellar was a man of marked originality of mind, which expressed itself in a singular absence of convention combined with an extreme tenacity of purpose. His schooling did not begin until he was 10 years of age, although taught to read at home, and he attributed his success at school and college to this mental freedom of his early years. At college he came specially under Kelvin's influence in natural philosophy, Lister's in medicine, and their influences were ruling factors in his life. While never neglecting an opportunity of adding to his medical knowledge, he found time for many recreative studies, which contributed to make him a broad scholar. He possessed a sound knowledge both of chemistry and mathematics, while engineering, wood turning, and wood engraving also occupied some of his attention. He was a proficient Latinist, could read French, German, and Italian fluently, and could speak the first tongue idiomatically.

His body was interred at Fulham New Cemetery on Feb. 27th.

#### THE LATE MR. ROBERT BRUCE.

Robert Bruce, M.R.C.S. Eng., L.S.A., D.P.H. Camb., who died in London on Feb. 3rd at the age of 63, was educated at the City of London School and St. Bartholomew's Hospital, qualifying in 1875 as L.S.A., and becoming in the following year a Member of the Royal College of Surgeons of England. He later obtained the Public Health diploma of Cambridge. After holding a resident appointment at the Borough Hospital, Birkenhead, he came to London, where he succeeded his father in practice at Old-street, St. Luke's, moving later to Finsbury. At this time he was a district surgeon to the City of London Lying-in Hospital. In 1890, on account of his wife's health, he went to Milford, where for 26 years he was untiring in the work of his profession and in promoting in other ways the well-being of his adopted home. The Milford Cottage Hospital owes its origin to his initiative. Outside his private practice Mr. Bruce was district medical officer and public vaccinator for the Lymington Union, Admiralty surgeon and agent, and surgeon in charge of the troops at Hurst Castle. He was a justice of the peace for the county of Southampton.

## The War.

### THE CASUALTY LIST.

The following names of medical officers appear among the casualties announced since our last issue:—

#### Killed.

Walker, Surg.-Prob. G. P., R.N.V.R.

#### Died.

Capt. G. S. Husband, D.S.O., I.M.S., received his medical education at Edinburgh and qualified in 1904. He entered the Service in 1907, and his D.S.O. was awarded early in June last year.

#### Slightly Wounded.

Surg. F. G. E. Hill, R.N.

### OBITUARY OF THE WAR.

#### JAMES FROUDE FLASHMAN, M.D. SYDNEY.

LIEUTENANT-COLONEL, AUSTRALIAN ARMY MEDICAL CORPS.

Lieutenant-Colonel J. F. Flashman, who recently died of pneumonia in France after a few days' illness, was a graduate of the University of Sydney, qualifying M.B. in 1894 and M.D. in 1897, and remaining there in practice at 183, Macquarie-street. He

came over with the Australian troops, and from November, 1915, until January, 1917, was attached to the 3rd London General Hospital at Wandsworth, where large numbers of the troops are treated. In January he wished to be nearer the front line, but soon succumbed to the inclement weather prevailing there.

Lieutenant-Colonel H. E. Bruce-Porter, to whose account of Colonel Flashman in the *Gazette of the 3rd London General*

*Hospital* we are indebted for the personal details, speaks of him as a man who threw himself heart and soul into the life and work of the hospital. "During the time he was here he endeared himself to everyone, both staff and patients, with whom he came in contact, and his cheery smile was good to see." We join with Colonel Bruce-Porter in heartfelt sympathy to Colonel Flashman's widow and children.

### DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

Able Seaman B. G. Richardson, Royal Naval Division, youngest son of Dr. C. Richardson, of Leeds.

Capt. N. West, M.C., Royal Berkshire Regiment, second son of Capt. C. J. West, R.A.M.C., of Newbury, Berks.

### THE HONOURS LIST.

The following awards to medical officers are announced:—

#### Distinguished Service Order.

Temp. Capt. Charles Owen Donovan, R.A.M.C., attached North Lancashire Regiment.

For conspicuous gallantry and devotion to duty. He displayed courage of a very high order over a period of 48 hours in attending to a large number of wounded of his own and other units in a shallow muddy trench, which was continually subjected to heavy fire. On another occasion he dressed several wounded officers in the open. He was severely wounded.

#### Military Cross.

Temp. Capt. George Noel Braham, R.A.M.C.

For conspicuous gallantry and devotion to duty. He with four others worked continuously under intense fire, and succeeded in rescuing several wounded men from the advanced dressing station, which was untenable. He set a fine example of courage and determination throughout.

#### Temp. Capt. John Crawford, R.A.M.C.

For conspicuous gallantry and devotion to duty. He took a party of stretcher-bearers to the position and proceeded to attend to the wounded under heavy fire. He set a fine example of courage and coolness throughout.

#### Temp. Capt. John Ferguson, R.A.M.C.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in tending to the wounded under the most intense hostile fire. Later, although himself wounded, he remained at his post until all the wounded men had been dressed.

#### Capt. Alaister Fraser Lee, R.A.M.C.

For conspicuous gallantry and devotion to duty in attending to a very large number of wounded under continuous heavy shell fire. He was thrown down and wounded by the explosion of a shell, but continued to perform his duties in the most gallant manner.

#### Temp. Capt. William Douglas Reid, R.A.M.C., attached Manchester Regiment.

For conspicuous gallantry and devotion to duty. He displayed great courage and skill in tending the wounded under heavy fire. Later, although himself wounded, he continued to dress the wounded of all units. He has previously done fine work.

#### Capt. David Christopher Vey, R.A.M.C., Spec. Res., attached East Lancashire Regiment.

For conspicuous gallantry and devotion to duty. He attended to the wounded in an open trench under very heavy fire. Later, he assisted to bring in many wounded men from the advanced trenches. He set a splendid example of courage and determination throughout.

#### Capt. Cyril James Berkeley Way, R.A.M.C., Spec. Res.

For conspicuous gallantry and devotion to duty. He repeatedly led his bearers through intense enemy barrages. He personally rescued several wounded men from shell-holes under machine-gun fire.

#### Capt. Charles Kingsley Parkinson, Aust. A.M.C.

For conspicuous gallantry and devotion to duty. He brought several wounded stretcher-bearers into the dressing-station under very heavy fire, thereby undoubtedly saving many lives. He set a splendid example of courage and determination throughout.

#### Foreign Decorations.

The following decorations conferred upon British medical officers are announced:—

#### By the King of Italy.

Officer of the Order of the Crown of Italy.—Fleet-Surg. R. Hughes, R.N.; Staff-Surg. T. W. Myles, R.N.

#### By the President of the French Republic.

Croix de Guerre with Palm.—Capt. A. G. Whitehorne-Cole, R.A.M.C.

### MENTIONED IN DESPATCHES.

The following names are to be added to those mentioned in the despatch received from Field-Marshal Sir Douglas Haig, G.C.B., reported in THE LANCET of Jan. 13th, p. 82:—

Col. R. E. Roth, D.S.O., V.D., Australian A.M.C.; Maj. H. L. St. V. Welch, Australian A.M.C.

### THE CENTRAL MEDICAL WAR COMMITTEE.

During the week the Executive Subcommittee have been considering the financial aspects of the mobilisation scheme for doctors, as well as the matters to be discussed at the forthcoming Conference arranged at the instance of the Director-General of National Service under the chairmanship of Sir Donald MacAlister. The Central Medical War Committee will be represented at the Conference by Mr. T. Jenner Verrall, the chairman of the Committee; Mr. Bishop Harman and Dr. Alfred Cox, the honorary secretaries of the Committee; Dr. C. Buttar, the chairman of the Executive Subcommittee; Mr. E. B. Turner; and Dr. B. A. Richmond, secretary of the London Panel Committee. The Committee of Reference of the English Royal Colleges will be represented by Dr. Frederick Taylor, and Sir Rickman Godlee, with Mr. F. G. Hallett, the honorary secretary of that Committee. Mr. Neville Chamberlain has accorded an interview already to Dr. Taylor, Mr. Verrall, Dr. Buttar, and Mr. Bishop Harman, at which the work of the Central Medical War Committee was fully explained, and there is no doubt that this clearing of the ground will be of use in the forthcoming Conference. The Scottish Medical Service Emergency Committee will be represented at the Conference by Dr. John Adams, vice-chairman of the Scottish Committee of the British Medical Association; Dr. John C. McVail, deputy chairman of the National Health Insurance Commission of Scotland; and Dr. Norman Walker, the convener of the Emergency Committee. Sir Donald MacAlister should therefore be presiding over a very business-like as well as representative group.

### THE WAR CRIPPLE: THE MINISTRY OF PENSIONS SCHEME.

The important statement made by Mr. Barnes, Minister of Pensions, last Tuesday in the House of Commons clears up the intentions of the Government towards the soldier crippled in the war.<sup>1</sup> Mr. Barnes described with candour the care and welfare of disabled men as the most backward part of the work of the Ministry, and announced that he had at last arrived at an agreement with the War Office on the crucial question: When should the wounded or invalidated man be discharged from the military hospital? His own original view that the man should be retained by the War Office until he was wholly cured or pronounced to be incurable had been modified by his experience of the effect of hospital life and discipline on the man's nervous temperament, and the agreement was now as follows:—

The War Office undertook to keep the wounded or invalidated man in the appropriate military hospital as an in-patient, so long as there was accommodation for him, and would include in the treatment appropriate manual curative treatment. After the man had been invalidated out, or declared to be no longer fit for service, the War Office would keep him in hospital another three weeks. During that time facilities would be given to the representative of the local Statutory Committee to see the man and the hospital authorities. Generally speaking, those three weeks were intended as a jumping-off place within which arrangements might be made for the man's subsequent treatment. As soon as the man was invalidated a card would be made out indicating the sort of treatment he needed. A duplicate of the card would be made, and one copy given to the man and one sent to the district in which he intended to reside. By these means the man would be saved from floating about the country without being in contact with any authority or body. The War Office also undertook to treat the man in his own district as an out-patient.

Mr. Barnes passed in review with warm commendation the various voluntary agencies which had up to now befriended the disabled sailor and soldier: instancing St. Dunstan's Hostel, the Star and Garter Home, the Queen Mary Convalescent Hospitals at Roehampton, the Hospitals for Orthopaedic Cases, the Scottish Red Cross, which dealt with the limbless men on the Clyde, the English Red Cross, and the Soldiers' and Sailors' Aid Society; and finally the War Pensions, &c., Statutory Committee. He then stated that he had sanctioned the setting up of a further Committee responsible to the Ministry of Pensions to deal in the first place with disabled soldiers requiring institutional treatment. This Committee was presided over by Colonel Sir A. Griffiths-Boecawen, Parliamentary Secretary to the Ministry of Pensions, and included Sir Walter Lawrence, representing the War Office, Mr. Cyril Jackson, vice-chairman of the Statutory Committee, and the Hon. Arthur Stanley, representing the British Red Cross. What is intended to be the relation of this new committee to the Statutory Committee itself Mr. Barnes did not state, but presumably the mechanism of the local Statutory Committees up and down the country will be utilised.

The Ministry intended, Mr. Barnes said, to provide new institutions for the disabled men and to make use of the material help, as well as the experience, of the Red Cross Society. One such institution had already been started for neurasthenics at Golders Green, London, N.W., and one for epileptics at Chalfont St. Giles, Bucks.

The difficulty in deciding on the allocation of the cost of dealing with the discharged war cripple between the State and the Approved Societies under the National Insurance Act had been met, he said, by an agreement that additional sickness should be a charge upon the State. Presumably this charge will also cover the added work thrown upon the panel practitioner, whatever this turns out to be in practice. The number of disabled men at present drawing pensions Mr. Barnes gave as 140,275, with an additional 65,000 or so medically unfit and 65,000 men in hospitals who had not yet reached the pension stage.

In the absence of military discipline after discharge from the Service, what pressure it was proposed to bring upon the disabled man to induce him to undergo proper treatment and training Mr. Barnes stated thus: The man who refuses treatment is to be fined half his pension; and the man who agrees to train for a new occupation is to be given

full pension, full separation allowance for his wife, and have his special training fees paid for him.

Mr. Barnes dealt also with the question of the medically unfit, of whom he was told that 100,000 had been passed into the Army, describing them as "veritable weeds, who never should have been there at all." Some of them, he said, had concealed their ailments, and thousands had not done more than two or three days' service. As the State must assume some responsibility for them, he proposed to put these men back where the State had found them with a small gratuity on a scale which had been drawn up. In exceptional cases the gratuity would amount to £100.

### *Sir Henry Norman's Report on the Treatment and Training of Disabled and Discharged Soldiers in France.*

The publication of the full text of Sir Henry Norman's report<sup>2</sup> has been delayed until the Ministry of Pensions Scheme was ready. Sir Henry Norman received a request on Sept. 21st last from Mr. Lloyd George, then Secretary of State for War, to report upon the French system and method of dealing with the problem of the medical treatment and training of disabled and discharged soldiers in France, both from the medical and administrative standpoints. The report as now printed begins with an account of the history and development of French administrative control, going on to describe in detail the principles of re-education of the war cripple and the means at disposal for carrying it out, and ending with suggestions regarding the treatment of disabled soldiers in the United Kingdom.

Sir Henry Norman describes the results of the French system of treating disablement as marvellous, and stated in the House of Commons on Tuesday that total disablement had almost ceased to exist in France. But he also fully realises the difficulty of voluntary re-education, saying:—

The difficulty is this. The Service of Health, which is part of the Ministry of War, deals, of course, only with soldiers. A man needing an artificial limb is sent to a centre of surgical equipment, which is always attached to a military hospital, and while receiving hospital treatment he may follow a course of re-education to fit him to return to his old trade or to take up a new one. This, however, is entirely voluntary; the best men gladly avail themselves of the opportunity, but a large number do not. These men, who often spend months in hospital, have the greater part of the day free; they are given leave, and spend their time sitting about the grounds or walking the streets, with results frequently disastrous to themselves. .... The inability of the State to control a man after he is discharged from the Army constitutes a very difficult problem, which will have to be faced in both countries.

Mr. Barnes's scheme faces these difficulties, and, it is to be hoped, may afford a solution of them; but Sir Henry Norman regards the half measures proposed as unsatisfactory. He calls attention also to the long waiting list at Roehampton and the Military Orthopaedic Hospital, Hammersmith. Further instruction may be derived from his characterisation of the strong and weak points of the French system:—

The strong points of the French system are the deep and universal sympathy felt for the disabled soldier; the national determination to do everything possible for him who has done so much for France; the keenness of all Ministers and officials to spare no effort and overlook no channel of usefulness; the readiness of Parliament to provide ample funds; the high scientific and specialist knowledge that is being devoted to the subject; and the desire that every part of France shall be prepared to offer to the disabled man the opportunity to return physically and intellectually re-equipped to civil life. All these things evoke one's profound admiration.

The weak points appear to be the absence of effective and authoritative coöordination; the dispersion of precious effort along parallel and even conflicting lines; the rivalry of different Ministries, none of which is willing to be dispossessed of functions it has exercised for a long time and which it regards as of paramount national importance; the retention by the military authorities of some activities which appear essentially those of civil administration; the undecided conflicts of technical opinion; and the increased expenditure resulting from the foregoing situation.

\* H.M. Stationery Office. Price 4d.

HAWARDEN CASTLE HOSPITAL.—Mr. Henry Gladstone has lent Hawarden Castle to the War Office for use as a hospital for wounded officers. Accommodation will be provided for 250 patients.

<sup>1</sup> See THE LANCET, March 3rd, p. 344.

**WOUNDED ALLIES RELIEF COMMITTEE.**—Twenty-two large cases of drugs and other hospital requisites have been sent out for the relief of the Roumanian Army by the committee. The contents of ten of these cases came from the Wounded Allies Relief Branch of the Kensington War Hospital Supply Depôt, 176, Cromwell-road, S.W., and included, among other things, 10,590 assorted swabs, 6369 bandages of various kinds, and considerably over 200 splints.

**THE WORK OF THE RED CROSS.**—The annual report and statement of accounts of the British Red Cross Society and the Order of St. John for the year ending October, 1916, is a record of a vast field of beneficent labour. Specially noteworthy is the lowness of the administration expenditure. Including the work at home and in all the theatres of war, excluding hospitals, this amounted to £85,298, or 6 67d. for every sovereign received. The income for the year was £3,064,232, an increase of more than £1,000,000 on the previous year. The total expenditure in 1916 was £1,815,353; of which the following details are of interest:—

Transport of wounded naturally accounts for the largest single item of expenditure. On the purchase and equipment of ambulances, soup kitchens, cars, wagons, and cycles—of which the societies now have 2522 in all, mostly working abroad—£205,593 were spent. Working costs—upkeep and maintenance—amounted to another £182,111. Transport of wounded cost £23,000 less than in 1915 for personnel, largely because, with the growth of their organisation, the Army authorities have taken over certain of the former Red Cross activities. In all, 1829 of the societies' ambulances are working in France and Flanders, others being spread over Egypt, Salonika, Mesopotamia, East Africa, Russia, Italy, and some 440 working at home.

Among their conclusions the committee state—

It is becoming increasingly necessary to determine the relative responsibilities of the Government and of organisations such as ours in this matter of the treatment and after-care of the men who have been disabled. The question is a very grave one, for such treatment must necessarily be continued for many years after the war. Its solution will depend in great measure on the pensions and allowances granted to disabled men, but to a still greater extent to the provision which the State may make for fitting these men, so far as possible, to take their part again in the civil work of the community.

The Report can be obtained, price 1s., from 83, Pall Mall, London, S.W.

The sale of gifts on behalf of the British Red Cross Society and the Order of St. John will be held on March 22nd and following days at Christie's Sale Rooms in King-street, St. James.

## Medical News.

**MEDICAL SICKNESS ANNUITY AND LIFE ASSURANCE FRIENDLY SOCIETY.**—The usual monthly committee meeting of this society was held on Feb. 16th, Dr. F. J. Allan being in the chair. The large number of claims arising from influenza during the previous month of necessity made the experience in excess of the expectation; but there is now a cessation of these claims, and appearances point to a possibility of a normal spring. For the first time for many years the half-pay experience of the society has been less than the expectation, and this is no doubt due to the more careful and rigorous medical examination that was enforced after the first year or two of the society's existence. After a period of inactivity of many years there has been introduced a new annuity table, which offers most facilities required for members desirous of obtaining deferred annuities. The society, therefore, now transacts the three forms of insurance for which it was originally founded, that is to say, sickness benefit during incapacity while a member is in active practice, annuity when this sickness benefit ceases, and life assurance to his representatives should he die. The annual report for 1916 was considered at this meeting and will be presented at the annual meeting of the members on March 27th. The society has laboured under more difficulties, it is thought, than any other insurance company; as dealing only with a specified profession, the majority of whose members are serving in H.M. Forces in various parts of the world, it is impossible to expect the normal increase

in new business which would have been experienced in ordinary times. In spite of this the report, as a whole, is satisfactory. Applicants for sickness insurance are no longer limited in the amount for which they can insure, provided such amount does not exceed three-fourths of the average professional earnings, and this regulation is being taken advantage of by many of the existing members in view of the high rates prevailing for locum tenens and cost of living generally. All further information may be obtained from the secretary, Medical Sick Society, 296, High Holborn, W.C.

Mr. W. Petersen has given £1000 to All-Saints' Hospital for Genito-Urinary Diseases, Vauxhall Bridge-road, for the endowment of a bed in memory of his son, who was killed in action.

**ASSOCIATION FOR PROMOTING THE TRAINING AND SUPPLY OF MIDWIVES.**—The twelfth annual meeting of this association will be held at 9, Queen Anne-street, London, W., on Thursday, March 22nd, at 3.30 P.M. The chair will be taken by Major A. P. Luff, R.A.M.C. (T.), and an address on Midwifery and Government Subsidies given by Dr. George Reid, county medical officer of Staffordshire.

**CHARITY ORGANISATION SOCIETY.**—The third of a series of lectures organised by this society on social subjects will be held at 34, Queen Anne's-gate, S.W., by invitation of Lady Glenconner, on Wednesday, March 21st, at 3.30 P.M. The lecturer, Dr. F. N. K. Menzies, principal assistant medical officer, London County Council, will deal with the prevention of consumption. Questions and discussion are invited after these lectures.

**MEDICAL MISSIONS IN CHINA.**—A joint conference of the National Medical Association of China and the China Medical Missionary Association was held from Jan. 24th to 30th at Canton, under the joint chairmanship of Dr. W. H. Venable and Dr. Wu Lien Teh, the respective presidents of the two associations. Valuable papers were read dealing with the medical work of the various missions, public health, and education. In the course of the proceedings the foundation-stone of the new Kung Yee Medical College was laid.

**THE MENTAL AFTER-CARE ASSOCIATION.**—At the annual meeting of this association, held on March 1st under the chairmanship of the Lord Mayor, Dr. Henry Rayner submitted the annual report, showing a substantial increase in the number of patients dealt with as well as a satisfactory financial situation. From this it appeared that gratitude often took the form of a repayment, in part of least, to the association when the patient's outlook became brighter. During the past year applications on behalf of 508 persons were received—viz., 371 women, 131 men—33 per cent. more than in 1915. 630 visits had been paid and 154 situations found. 203 patients spent varying periods in cottage homes. A successful branch is in operation in Birmingham. Sir William Collins, M.P., in proposing the adoption of the report, described the association as the guide, philosopher, and friend of those who, happily recovered from their acute mental condition, sought to take their place in the world again. Sir D. Brynmor Jones, who seconded the resolution, pointed out the useful place which the association filled, inasmuch as the discharge of a patient from an asylum did not necessarily imply immediate fitness to resume control of property or business without assistance.

**QUEEN CHARLOTTE'S LYING-IN HOSPITAL.**—At the recent annual meeting of governors it was reported that there had been a large increase in the number of patients admitted to the wards in 1916—namely, 2075 as compared with 1817 in 1915—and 2053 had been attended at home by the hospital midwives. Of the in-patients 407, and of the out-patients 911, were the wives of sailors and soldiers. In order to cope with the increasing work of the ante-natal department, a new and temporary out-patient department has been opened adjoining the hospital, and a physician, Miss Frances M. Huxley, M.D., has been appointed in charge. An infant consultation centre is also being opened, and a physician, Miss Margaret G. Thackrah, M.D., has been appointed in charge. The number of emergency cases admitted, the report stated, had been greater than ever. Last year there were 183, many of them being admitted in a grave condition and suffering from severe complications. The work has been carried on under difficult conditions owing to shortage of nurses, but the training school has maintained its reputation, only one candidate having failed to pass the Central Midwives Board examination out of 113 candidates. The Ladies' Association continues to give valuable assistance. A strong appeal is being made for liberal support to enable the committee to pay off the balance, nearly £2000, of the accumulated debt and to meet the cost of maintenance during the current year.

## Parliamentary Intelligence.

### NOTES ON CURRENT TOPICS.

#### Legislation on Venereal Disease.

**LORD RHONDDA**, the President of the Local Government Board, formally introduced in the House of Lords on March 6th a Bill to prohibit the treatment of venereal disease otherwise than by duly qualified medical practitioners, and to prevent the sale of quack remedies.

The text of the Bill is as follows:—

(1) In any area in which this Act is in operation, a person shall not, unless he is a duly qualified medical practitioner, for reward either direct or indirect, treat any person for venereal disease or prescribe any remedy therefor, or give any advice in connection with the treatment thereof, whether the advice is given to the person to be treated or to any other person.

(2) In any area in which this Act is in operation, a person shall not sell, offer for sale, supply, offer to supply, or dispense any drug or medicinal or other preparation as a remedy for venereal disease, unless the remedy is dispensed on, and in accordance with the written prescription of a duly qualified medical practitioner, and is supplied for the use of the person for whom the remedy has been prescribed: Provided that nothing in this section shall affect (a) the sale or supply of any such drug or preparation by, or to, a duly qualified medical practitioner; or (b) the wholesale sale or supply of any such drug or preparation.

(3) If any person acts in contravention of any of the provisions of this section, he shall be liable on conviction on indictment to imprisonment, with or without hard labour, for a term not exceeding two years, or on summary conviction to a fine not exceeding one hundred pounds, or to imprisonment with or without hard labour for a term not exceeding six months.

(4) In this Act the expression "venereal disease" means syphilis, gonorrhoea, or soft chancre, or any disease of the genito-urinary organs which may reasonably be suspected to be venereal disease.

The Act, if it becomes law, is to operate in any area to which it is applied by order of the Local Government Boards in the United Kingdom.

#### Criminal Law Amendment Bill.

A Grand Committee of the House of Commons began the detailed consideration of the Criminal Law Amendment Bill on March 6th. Having postponed the consideration of Clause 1 (punishment of acts of indecency with girls under 16), the Committee proceeded to deal with Clause 2, which prohibits under penalty sexual intercourse by a person suffering from venereal disease. The progress made with the consideration of the clause was not very great, and at the conclusion of the sitting the first subsection was still under examination. That subsection, as it was originally printed in the Bill, runs:—

A person who is suffering from venereal disease in a communicable form shall not have sexual intercourse with any other person or solicit or invite any other person to have such sexual intercourse.

An amendment was inserted in the subsection which provided that the person suffering from the disease should not only not have sexual intercourse with any other person, but should not "wilfully communicate such disease in any other manner to any person." Some discussion arose on the application of the penalties to solicitation by infected persons.—Answering Sir WILLIAM COLLINS, Sir GEORGE CAVE, the Home Secretary, said that he would ask the Committee to omit Subsection 3 from the Bill. That is the provision which runs:—

Where any person is convicted of any of the offences mentioned in the Schedule to this Act, the Court may, if they think fit, for the purpose of ascertaining whether that person is suffering from venereal disease in a communicable form, order that person to submit to such medical examination and tests as may be requisite for that purpose. If the person is a female, the examination and tests shall be conducted, if she so desires, by a female doctor.

He (the Home Secretary) thought that there were good reasons for inserting such a provision as this, but there was strong opposition to it. As it was thus shown to be controversial, he would not press for its insertion. The Committee left off its proceedings at this stage.

#### Pensions for Disabled Soldiers and their Dependents.

In the House of Commons on Tuesday a very detailed statement was made on the subject of pensions to disabled soldiers, and to soldiers' widows and dependents by Mr. BARNEs, the Minister of Pensions.<sup>1</sup> One other point which Mr. Barnes touched on is interesting to the medical profession. Power is to be taken under the Royal Warrant to retain a penny in each half-crown from the pension of any widow for any benefit which the Government may devise. If a scheme of medical benefit is devised (Mr. Barnes said) this would enable the Government to place the 400,000 women and children under the doctors' supervision. He intimated that he would be glad to have the mind of the House on the matter. F.W.

## HOUSE OF COMMONS.

WEDNESDAY, FEB. 28TH.

#### Health of Troops in East Africa.

Answering Mr. O'GRADY, Mr. MACPHERSON (Under Secretary for War) said: The composition of the East African Expeditionary Force has been varied from time to time according to the climatic and other conditions under which it was operating. It was long since recognised that in the event of the German forces retiring into the malarious south-eastern portions of their colony it would be desirable to reduce the number of white troops employed to a minimum. Steps were accordingly taken to provide coloured units to replace white. At the present moment the bulk of the white troops have been withdrawn or are in process of being withdrawn, whilst arrangements have been made to give other white units a period of rest and recuperation in a healthy climate. In regard to certain reports of the hardships undergone by the troops in East Africa which have gained currency, the following extract from a telegram from General Smuts may be of interest: "The complaints are exaggerated perversions of the admitted fact that the hardships have been unusually great in this campaign." The health and rationing of the troops and the provision of adequate transport, mechanical and other, is constantly engaging attention.

THURSDAY, MARCH 1ST.

#### The Health of the Army.

In the course of his speech introducing the Army Estimates, Mr. FORSTER (Financial Secretary to the War Office) said: While I am speaking of Mesopotamia, may I refer to a subject which engaged a deal of attention last year—namely, the condition of the Medical Service. Since the estimates were introduced last year, the War Office has become directly responsible for the medical arrangements in that theatre of war. We have received frequent reports from the medical and sanitary authorities of that force. The Special Sanitary Committee made an exhaustive examination of the conditions existing there, and the general conditions now existing may be regarded as fully satisfactory. During the summer there was necessarily some considerable sickness, but the admission ratio has steadily diminished since then, and I think the health of the Army at present may be considered satisfactory. An abundant supply of nurses and other medical personnel has been furnished in hospitals for that area. These hospitals have recently been visited by a representative from the War Office, who reports that they are not unequal to any of the hospitals which we have at the other fronts. In France, Salonika, and Egypt the general condition of affairs is satisfactory. A great strain has at different times been put upon the medical resources in the various theatres of war, but the difficulties have been met. We have had to contend with a good deal of malaria in East Africa owing to the exceptionally unhealthy climatic conditions in which we have had to carry on our operations. I think nothing in this war is more striking than the triumph of science over disease, wholly upsetting the experience of former wars.

#### Enteric Fever.

One of the most remarkable phenomena is the almost total disappearance of enteric fever, that dread scourge which in former wars has decimated our armies even more effectually than the efforts of the enemy. This is the more surprising when one considers the vast numbers of men, their density on the ground, and the poisoned condition of the soil, especially in France. I think it will interest the House if I give the last weekly returns from the various fronts of the numbers in hospital suffering from typhoid. In France there are 4 cases, in Salonika 9, in Egypt 3, and in Mesopotamia 3, making a total of 24. The number of cases of typhoid fever amongst British troops in France up to Nov. 1st last year was 1684, paratyphoid 2534 and indefinite cases 353, a total of 4571 cases of the typhoid group of diseases. Compare that with what happened in South Africa. In South Africa there were nearly 60,000 cases admitted to hospital and 8227 deaths. And the army in France is infinitely larger than was the army in South Africa. The admission ratio for typhoid fever amongst the troops in France who have not been protected by inoculation is 15 times higher than amongst those who have been inoculated and the death ratio 70 times higher. I think that the narration of figures like these bears eloquent witness to the debt which we owe to the medical service.

#### Hospital Services.

At home during the past year (Mr. Forster proceeded) a system of convalescent hospitals, command depots, and orthopaedic hospitals has been developed and extended. Arrangements have been made with the Ministry of Pensions by which the problem of the training and treatment of the discharged soldier will be more effectively dealt with, and arrangements have been made to link up the treatment in the military hospitals with that afforded to discharged

<sup>1</sup> This statement is summarised on p. 393.

soldiers on the out-patient system under the local committees of the Statutory Committee on War Pensions. The strain on the Medical Department in providing accommodation for the sick and wounded from the various fronts overseas has been very great, but we have received, and we continue to receive, the most valuable assistance from the voluntary hospitals which have been established throughout the country by persons to whom we are greatly indebted. The system of utilising the services of the members of the various Voluntary Aid Detachments has been highly successful. Those ladies serve abroad in large numbers and they are highly appreciated by members of the nursing profession. A system of Voluntary Aid hospitals has been invaluable in linking up the military medical system with the large number of sympathetic workers amongst the civil population, and I am glad to take this opportunity of saying how deeply indebted we are for the assistance we have received. The work of the British Red Cross Society is too well known to need any encomiums. The great resources of the society have been ungrudgingly placed at the disposal of the Medical Department on many occasions. A special committee has been recently established by that society, upon which are representatives both of the War Office and the Ministry of Pensions, for dealing with certain classes of disabled soldiers, such as neurasthenics, epileptics, and other cases requiring institutional treatment. This still further strengthens the link between the military hospitals and the civil institutions.

#### *Venereal Disease.*

I think it should be generally known that the venereal rate in the Army to-day is no higher than it is in ordinary times of peace. The absence of statistics for the general population in pre-war days renders it impossible to say whether the number of cases of venereal disease in the Army is higher than in a corresponding portion of the civil population of corresponding ages. We are making every effort to reduce the rate still lower. The National Council for the Control of Venereal Diseases has given us great assistance by providing lecturers specially chosen to lecture to troops in camps and barracks. These lectures have been largely attended and much appreciated.

Mr. TENNANT commented on the marvellous immunity of the Army from epidemic disease. "I think the House will agree," he added, "that the person more responsible than any other for the happy state of affairs is the Director-General of the Medical Services, Sir Alfred Keogh."

#### *R.A.M.C. Territorial Officers.*

Major WHEELER drew attention to the position of the junior officers of the Royal Army Medical Corps Territorial Branch. He gave figures relating to their pay in comparison with that of regular and temporary officers of the R.A.M.C. Both as to pay and conditions of service the officers of the Territorial Branch were at a disadvantage, and their case was worthy of the consideration of the War Office.

Mr. MACPHERSON (Under Secretary for War) announced that the Secretary for War had appointed a committee to inquire into the various anomalies of promotion, not only in the Territorial Force, but in the New Armies. He had no doubt that the point raised by the honourable and gallant Member concerning the Territorial R.A.M.C. men would be included in the terms of reference.

#### *Military Medical Boards and Classification of Recruits.*

Mr. NIELD moved—

That, in the opinion of this House, the classification of recruits for the Army by military medical boards, particularly of men who have been previously examined upon attestation under the Derby scheme and rejected as unfit, has been productive of great and unnecessary hardship as well as expense by reason of the large number of such men, while undergoing training, being found unable to perform the military work required of them in the class to which they have been assigned, whereby they have had to be sent for hospital treatment and have occupied accommodation and medical attendance urgently required for returned wounded men; and this House is of opinion that an inquiry is urgently needed to alter and standardise these medical examinations and to ascertain the extent to which hospital accommodation and expense has been expended which with proper care might have been avoided.

The honourable Member said that great waste was taking place in hospitals because men who were taken into the Army and had been unable to stand the strain of training had been relegated to hospitals and filled beds which were urgently wanted for wounded men. There was also the waste of man power occasioned by withdrawing men from civil occupations when they ought to be left in them. All over the country medical boards refused to re-examine attested men. The honourable gentleman went into great detail in individual cases, which, he said, showed laxity of the medical authorities under the tribunals scheme. He had a list of men who had been passed in certain categories in a way which no possible system could justify. He called particular attention to the case of men who were suffering from gastric trouble. He also referred to the careless

way in which he said some medical examinations were conducted.

Mr. SNOWDEN seconded.

Mr. MACPHERSON, in replying, said a million and a half men had probably been examined in a comparatively short time. It would have been exceedingly surprising if out of such a large number some mistakes had not been made. One per cent. of the number would amount to 15,000 cases, and he thought it might be safely said that mistakes had not been made in greater number than that. In fact, probably a less number had been made. Of course, to get out accurate statistics would cost an enormous amount of time and expense, but he was sure it would be found not only that the mistakes had been small in number, but, on the whole, recruiting medical boards had done extraordinarily well. The suggestion which pervaded the speeches of the two honourable members was that the military doctors were responsible. As a matter of fact, the boards in the main were composed of civilian practitioners belonging to the Territorial Force and the Special Reserve. He had taken 63 medical boards and had found that the proportion of civilian to military doctors was as two to one, and the proportion of civilian to military doctors would work out at a very much higher rate if it were not necessary to have a medical man of military experience as president of the Board. He must, therefore, deny that the R.A.M.C. doctors were responsible.

- Mr. SNOWDEN: I did not make that suggestion.

Mr. MACPHERSON went on to say that it had been stated that the medical men were receiving secret instructions from the War Office. That was rather a monstrous charge to make. They were professional men and in a great many cases were men of very high professional and social reputation. He could not imagine medical men of that status and character accepting secret instructions of any sort. He had a greater faith in the British medical practitioner. At the head of these boards was a distinguished practitioner, Colonel James Galloway. He was the man who was responsible for the conduct of the boards and his qualifications, as the House would appreciate, were very high. To suggest that he was in any way responsible for secret instructions to boards was stretching common-sense. The point had also been made that the re-examination of attested men was very unsatisfactory. There, again, when they were dealing with a specific case it was almost impossible to answer. In recent statistics he found in the time covered by the opening period of this year that in a total of 2000 only 13 broke down in training. This was certainly not a high percentage when the different classes from which the men were drawn and the training that was undergone were considered. He would engage to make all inquiries in the cases that had been submitted to him.

Mr. NIELD: Will the honourable gentleman regard gastric cases as a class apart and give special directions?

Mr. MACPHERSON: I will bring the cases mentioned before the proper authority.

The motion was withdrawn.

MONDAY, MARCH 5TH.

#### *Payments to Panel Practitioners.*

Mr. CHANCELLOR asked the representative of the National Health Insurance Commissioners whether he was aware that certain Insurance Committees declined to pay the balances due to practitioners in respect of the year 1915 unless a special form of receipt and discharge was signed; and whether, as these moneys were payable unconditionally, he would take steps to see that the doctors concerned should receive equitable treatment and thus, by assuaging irritation, lighten their burdens during the pressure of work consequent upon the depletion of their numbers through enlistment.—Sir E. CORNWALL replied: No particular form of receipt has been prescribed by the Commissioners, but I shall be glad to consider in any particular case which my honourable friend has in mind any proposals in this direction calculated to remove irritation or lighten the pressure of work falling upon medical men, especially in view of the depletion of their numbers.

#### *Brandy for Hospitals.*

Sir G. TOUCHE asked the representative of the Treasury whether he was aware that the application of the restrictions governing the withdrawal of spirits from bond was resulting in hardship in the case of hospitals, both military and civil, on account of the inability of retailers to supply the small quantities of brandy necessary for their consumption due to their inability to show an average, owing to their varying needs which were dependent on the nature of the cases under treatment, and that representations made on behalf of the Great Northern Central Hospital to the Customs authorities pointing out that their consumption was two gallons every ten days, that they were now using their last two gallons, and that their suppliers were unable to withdraw a further quantity from bond, only resulted in a promise to place the subject before the Board

with a view to an inquiry being held and a statement that some weeks might elapse before a decision was arrived at; and, in view of the fact that the application of the restrictions in such cases could not be in the public interest, and having regard to the necessity for the maintenance of an adequate supply of brandy for use in the treatment of wounded soldiers, would he take such steps as would procure a modification of the regulations in so far as they governed the supply of brandy to hospitals.—Mr. BALDWIN wrote in reply: The Board of Customs and Excise informs me that, while they can identify the case referred to, they had no knowledge that the situation was as described in the question. No representations have been made to them by the hospitals as to the effect upon them of the present regulations, but they are inquiring further into the case of this hospital.

TUESDAY, MARCH 6TH.

*American Medical Men.*

Answering Mr. R. LAMBERT, who asked whether the Army Medical Department would relax the rule which deprived them of the services of medical men holding American degrees, Mr. MACPHERSON (Under Secretary for War) said: The War Office is in constant touch with members of the medical profession. Duly qualified American doctors are being employed.

**Appointments.**

*Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

DUNCAN, D., M.B., C.M. Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Chester-le-Street District of the county of Durham.  
DYSON, WILLIAM, M.D. Vict., Dermatologist to the Salford Royal Hospital; GIBSON, ROBERT, M.D., Ch.B., to hold the office *pro tem.*  
MACALPIN, J. BARLOW, M.B., Ch.B. Vict., F.R.C.S. Eng., to take charge of the Genito-Urinary Department at the Royal Salford Hospital.  
MAGDONALD, M., M.D. Glasg., Acting Medical Officer of Health *pro tem.* to the Deptford Borough Council.  
MALLINICK, S., M.B.C.S. Eng., L.R.C.P. Lond., Assistant Tuberculosis Officer for the Cardigan and Middleton-in-Wharfedale Sanatoria.  
OLIPHANT, F. B., M.B., C.M. Edin., Certifying Surgeon under the Factory and Workshop Acts for the Bridport District of the county of Dorset.  
SMITH, F. L., M.D. Durh., Medical Officer of the Grimoldby District of Louth.

**Vacancies.**

*For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.*

ASHTON-UNDER-LYNE, LANCS, DISTRICT INFIRMARY AND CHILDREN'S HOSPITAL.—Assistant House Surgeon. Salary £160 per annum, with usual emoluments.  
BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Female House Surgeon. Salary £200 per annum.  
BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £250 per annum, with apartments, &c.  
BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Female House Surgeon. Salary £160 per annum, with board, &c.  
BRISTOL ROYAL INFIRMIERY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.  
BURNLEY UNION.—Resident Assistant Medical Officer. Salary £250 per annum, with rations, &c.  
BURNLEY, VICTORIA HOSPITAL.—House Surgeon. Salary £160 per annum, with board, &c.  
BURRY INFIRMARY.—Junior House Surgeon. Salary £150 per annum, with board, &c.  
CAMBRIDGE, COUNTY MENTAL HOSPITAL.—First Assistant Medical Officer. Also Junior (Second) Assistant Medical Officer, unmarried. Salaries £200 and £200 respectively, with board, &c.  
CARLISLE, CUMBERLAND INFIRMARY.—House Surgeon. Salary £200 per annum, with board, &c.  
CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House Surgeon. Salary £200 per annum, with board, &c.  
DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant House Surgeon, unmarried. Salary £150 per annum, with board, &c.  
GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £250 per annum, with board, &c.  
LEEDS PUBLIC DISPENSARY.—Second Female Resident Medical Officer. Salary £200 per annum, with board, &c.

LIVERPOOL, BROWNLOW HILL INSTITUTION.—Resident Assistant Medical Officer. Salary at rate of £300 per annum, with rations, &c.  
MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Senior House Surgeon. Salary £250-£300 per annum.  
MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road.—House Surgeon. Salary £120 per annum, with board, &c.  
NEWCASTLE UPON-TYNE EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary £300 per annum.  
OLDHAM ROYAL INFIRMARY.—Second House Surgeon. Salary £250 per annum. Also Third House Surgeon. Salary £200 per annum. With board, &c.

PETERBOROUGH INFIRMARY.—House Surgeon. Salary £150 per annum for first six months, £200 after, with board, &c.

PORTSMOUTH ROYAL HOSPITAL.—House Surgeon for six months. Salary £250 per annum, with board, &c.

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford.—House Surgeon. Also Casualty Officer.

READING, ROYAL BERKSHIRE HOSPITAL.—House Surgeon for six months. Salary £250 per annum, with board, &c.

ST. GEORGE'S HOSPITAL, Hyde Park Corner, S.W.—Lecturer on Mental Diseases.

SALFORD ROYAL HOSPITAL.—Junior House Surgeon. Salary at rate of £150 per annum, with board, &c.

SOUTHAMPTON BOROUGH ISOLATION HOSPITAL.—Resident Medical Officer. Salary £200 per annum, with board, &c.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician and Junior House Surgeon. Salaries £150 and £120 per annum respectively, with board, &c.

SUNDERLAND ROYAL INFIRMARY.—Female House Surgeons. Salaries—Senior, £250; Junior, £200 per annum, with board, &c.

WARRINGTON INFIRMARY AND DISPENSARY.—Senior and Junior House Surgeons. Salary £200 and £150 per annum respectively, with board, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Gravesend.

**Births, Marriages, and Deaths.****BIRTHS.**

COWEN.—On March 1st, at Imperial-terrace, Blackpool, the wife of Captain E. G. H. Cowen, R.A.M.C., of a son.

DICKSON.—On March 4th, at Nelson Place, Newcastle, Staffordshire, the wife of Robert H. Dickson, F.R.C.S.—a son.

FITZGERALD.—On March 1st, at St. Margaret's, Ashburnham-gardens, Eastbourne, the wife of Captain R. Desmoden Fitzgerald, R.A.M.C., of a son.

GARDNER.—On March 2nd, at Albert-road, Whalley Range, Manchester, Muriel, wife of Lieutenant A. Linton Gardner, R.A.M.C., of Watermead, Ilfracombe, of a son.

JOHN.—On Feb. 25th, at "Tandderwen," Old Colwyn, to Katharine (née Spencer), the wife of Captain R. B. John, R.A.M.C.—a son.

**MARRIAGES.**

CADDELL—WHELAN.—On Feb. 22nd, at the Chapel Royal, Savoy-Captain (Acting Lieutenant-Colonel) E. D. Caddell, M.B., M.C., R.A.M.C., to Margaret Frances, only daughter of Mr. and Mrs. C. Pratt Whelan, Allesbury-road, Dublin, and Rochfort, Greystones, Co. Wicklow.

FARNFIELD—WINDSOR-WATSON.—On Wednesday, March 7th, 1917, at All Souls', Hastings, by the Rev. H. Collinson, B.A., John Stewart Farnfield, M.R.C.S., L.R.C.P., London, to Annabel Windsor-Watson, widow of John Watson, solicitor, Liverpool.

## Notes, Short Comments, and Answers to Correspondents.

### FERNS AS A SOURCE OF STARCH.

To the Editor of THE LANCET.

SIR.—With reference to the annotation in THE LANCET of Feb. 24th and Professor A. E. Shipley's suggestion regarding the use of the rootstock of the common brake (*Pteris aquilina*) as a possible source of starch for food and industry, there seems to be some doubt as to its capabilities in these directions, judging by the remarks of various writers. The best account I have been able to find is in "The Ferns of Great Britain, &c.," by Anne Pratt (Mrs. John Pearless in 1866), as follows:—

The ancients are supposed to have used both the fronds and stems of the Brake in diet-drinks, and medicine, for many disorders have, at various times, been made in our country from this fern. It is very astringent, and has been recommended for dressing and preparing kid and chamois leather; while both in this and other lands the ashes, from the alkali which they contain, were found serviceable in the manufacture of soap and glass until discoveries in chemistry suggested the use of other materials for the purpose. This very astringency seems to render the Brake unsuitable for the food of man, though some writers think that nutriment would be afforded by its large rhizome. This is often ground to powder and mixed with the flour in bread eaten in some parts of Normandy; but, perhaps, like the admixture of pine bark with the flour used in some countries in the north of Europe, it adds rather to the quantity than to the nutritious quality of the bread. The rootstock of this brake, however, as we are informed by Humboldt, serves the inhabitants of Palma and Gomera, in the Canary Islands, for food. They grind it, he says, to powder and mix it with a small quantity of barley-meal. This composition is termed "*gofio*"; and the author adds that the use of so homely a diet is a proof of the extreme poverty of the people of these islands. This naturalist saw both the Brake and our common Northern Hard Fern growing in the Canaries in great luxuriance, though never attaining the size or stateliness of the arborescent forms of Equinoctial America. Tree ferns frequently afford food to the natives of the lands in which they are found. Dr. Joseph Hooker, in his recent "Himalayan Journal," says that ferns are more commonly used for food than is supposed. He tells us that both in Sikkim and Nepal the watery tubers of an *Aspidium* are eaten. So, also, the pulp of one tree-fern affords food, but only in times of scarcity, as does that of another species in New Zealand, *Cyathea medullaris*. Their pith is composed of a coarse sago—that is to say, of cellular tissue with starch granules. The Esculent Brake (*Pteris excelsa*), a fern very similar to our Bracken, is a very troublesome plant to the agriculturist in his attempt to clear the land in New Zealand, and Polack calls it "the interminable fern-root." The rootstock is much used by the natives as food, as it is also in the Society Islands and in Australia, where it is the most extensively diffused edible root. In the latter country this plant is called *Tara* by the aborigines, a name which in the southern hemisphere is given to several roots which are eaten, and also to rice. Mr. Backhouse states, with some of the natives of Australia, the meal made of the inner portion of the upper parts of a tree-fern. He says that it was too astringent to be agreeable to his palate, and little improved by cooking, but that it was something like a Swedish turnip in substance.

The fronds have been used in the manufacture of beer and are still used as packing material for fruit, keeping it fresh and cool and imparting neither colour nor flavour; but in the "Diary of Henry Machyn, Merchant Taylor of London," written in 1552, we read of a wicked man who was placed in the "pelere" for "selling pots of strawberries, the whiche the gott was not alif fulle, but filled with forne."

I am, Sir, yours faithfully,

London, March 3rd, 1917.

PTERIS.

**PRUDENTIAL ASSURANCE COMPANY, LIMITED.**  
THIS company has just issued its sixty-eighth annual report for the year ending Dec. 31st, 1916. The assets of the company in all branches as shown in the balance-sheet are £99,123,746, being an increase of £4,328,948 over those of 1915. Of these assets over £17,750,000 are in British Government securities; this represents an increase compared with last year of about £4,500,000. During the year the company has lent or sold to the Treasury under the various mobilisation schemes securities of a nominal value of £6,955,159, and in the same time the Government has continuously availed itself of the services of the company and its officials, and the report states that it has been a matter for congratulation that the services so rendered have met with the greatest appreciation. The indoor and outdoor staffs have been further depleted during the year by naval and military demands, and the company is now supplying more than 10,000 men to the fighting strength of the nation. The directors record their admiration of the spirit with which the staff, male and female, have carried on the business of the company, a task which the war has rendered difficult of accomplishment. The Prudential Voluntary Aid Detachments of the Red Cross Society have continued their work throughout the year; the number of casualties met at the various railway stations and conveyed to London homes and hospitals have now reached a total of 156,000. Two

motor ambulances were purchased by the voluntary subscriptions of the outdoor staff of the company and presented to the Red Cross, and a motor omnibus was presented by Mr. Thomas Wharrie, whose death, after 24 years' continuous service on the board, the directors deplore. The board propose to fill the vacancy by the appointment of Mr. Alfred Corderoy Thompson, who has served the company for nearly 45 years and who has held the office of manager since 1907. The directors desire that he should retain his present office of general manager, which will necessitate an alteration in the articles of association of the company. The war claims during the year in both the ordinary and industrial branches number 52,433, and amount to £1,077,568. The total paid up to the present on this account since the outbreak of war exceeds £1,850,000 in respect of over 88,000 claims. The strain imposed upon the company by the operation of the Courts (Emergency Powers) Act and the necessity of reserving funds to meet the liabilities which this Act creates and other strains owing to war have reduced the surplus shown on the financial operations of the year, and profit-sharing schemes have either had to be temporarily suspended or modified. Mr. J. Burn, actuary, in his valuation report states that the war claims of the year have been very heavy, the amount paid in the industrial branch being almost double that paid in the previous year. He also emphasises the strain imposed by the Act referred to as "a severe burden upon the company's resources."

### THE PRICE OF FISH.

To the Editor of THE LANCET.

SIR.—I do not propose to comment on the price of fish generally, but to compare the values and prices of two favourites with many less wealthy folk. These favourites are bloaters and fresh herrings and, on Sundays especially, winkles (if a winkle is a fish, a point which I seem to recollect a learned judge could not decide; to some it is a contemptible sea-snail). Winkles are now in London 4d. a pint (except in the very poorest districts, where they are 2d.). I bought a pint and obtained 154 shells, weighing 19 oz. The empty shells weighed 15*1*/<sub>2</sub> oz. and the actual winkles 3*1*/<sub>2</sub> oz. This equals 1*1*/<sub>2</sub> d. per pound for winkles, or just over 1d. an ounce. (Before the war winkles in shells were 2d. a pint, equal to 8*1*/<sub>2</sub> d. a pound for the yield.) I bought two bloaters costing the same money as the winkles, 4d. (2d. each). They weighed, with heads on, 10*1*/<sub>2</sub> oz. and without heads 8*1*/<sub>2</sub> oz. This equals 7*1*/<sub>2</sub> d. a pound for bloaters. I also bought two fresh herrings costing the same money, 4d. (2d. each). They weighed, with heads on 9*1*/<sub>2</sub> oz. and without heads 8 oz. This equals 8d. a pound, or 4d. an ounce. Winkles are therefore proved to be double the price of bloaters or herrings, if considered as food. Some people may argue that they are a relish used in place of jam, but plum jam is 8d. a pound and strawberry, 10*1*/<sub>2</sub> d., as against 1*1*/<sub>2</sub> d. for winkles, which even at the lowest price, 2*1*/<sub>2</sub> d. a pint, now current, work out at 1*1*/<sub>2</sub> d. a pound. Sixty-five years ago a Fellow of the Statistical Society (Mr. Braithwaite Poole) estimated that Billingsgate Market sold in a year 304,000,000 winkles, weighing 1900 tons, with a value of £15,000. Food experts have ignored the winkle (and the cockle) as of little account as food, but that was when plenty reigned.

I am, Sir, yours faithfully,

OBSERVER.

### FALKLAND ISLANDS.

THE Blue-Book of this colony for 1915 gives the estimated population as 3451—2519 males and 932 females. The birth-rate per 1000 during the year was 13.37 and the death-rate 8.13. The general health was good on the whole, but that of the workmen imported into Stanley from England for special work was less satisfactory, the chief illnesses among them being bronchitis, rheumatism, and enteritis; many cases of the last were probably due to excessive meat-eating, to which the majority of the men were not accustomed. An epidemic of a peculiar kind occurred during July, August, and September and resulted in five deaths; the symptoms simulated very closely those of beri-beri; no cases occurred in Stanley. The King Edward VII. Memorial Hospital was opened as a civil hospital in May; 21 cases were admitted to the institution during the year.

### POTATOES.

To the Editor of THE LANCET.

SIR.—With reference to Captain Bathurst's warning in the House of Commons yesterday that there will probably be no potatoes at all for sale during the late spring and early summer, and his added appeal to those able to buy more expensive substitutes to do so at once, and thus to make the supply last longer for their poorer brethren, may I recommend the following method to make the potatoes go further and to comply with the appeal? Boil two or three tablespoonfuls of ordinary rice (in a cloth preferably) in order not to make the rice too watery, allowing

room in the cloth for the expansion of the rice grains) about an hour before one pound of potatoes are put on to cook. When the potatoes are boiled, mash them, and add the rice which has been boiled soft, and mix well together. Three people out of four who were served with this mixture did not know until afterwards that they had not eaten solely mashed potatoes. 3d. a pound was paid for the rice, which was of the small variety, but nice and white. Not much rice to the pound of potatoes is required, as the rice grains swell up considerably. Personally I can recommend it.

London, March 6th, 1917. 1 am, Sir, yours faithfully,

W.

#### THE STICK CRUTCH FUND.

A DEPOT of this Fund has been opened at 30, Regent-street, W., for supplying, free of charge, stick crutches to wounded soldiers discharged from the Army. The office is open from 11 A.M. to 4 P.M. each week-day with the exception of Saturdays.

## Medical Diary for the ensuing Week.

### SOCIETIES.

#### ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W. MEETINGS OF SECTIONS.

Tuesday, March 13th.

**PSYCHIATRY** (Hon. Secretaries—Bernard Hart, G. F. Barham):  
at 6.30 P.M.  
*Communications:*  
Dr. Laura Foster: Histological Examination of the Ovaries in 100 Cases of Mental Disease and Normal Controls.  
Staff-Surgeon M. Kojima, I.J.N.: Studies on Endocrine Organs of Dementia Praecox.  
(Communicated by Major F. W. Mott, who will demonstrate the histological observations.)

Wednesday, March 14th.

**SURGERY** (Hon. Secretaries—Raymond Johnson, V. Warren Low):  
at 6.30 P.M.  
*Paper:*

Major Jocelyn Swan: The Treatment of Severely Infected Gunshot Fractures involving the Joints of the Upper Extremity: Early Excision with the object of obtaining Mobility (with epidiascope demonstration of radiograms, &c.).

Thursday, March 15th.

**DERMATOLOGY** (Hon. Secretaries—J. H. R. McDonagh, Henry MacCormac): at 5 P.M.  
*Cases* (at 4.30 P.M.).

Dr. Pernet: (1) A Case of Morvan's Disease (Syringomyelia); (2) A Case of Elephantiasis of the finger; (3) A Case of Nævus of the temple; And other cases.

Friday, March 16th.

**ELECTRO-THERAPEUTICS** (Hon. Secretaries—E. P. Cumberbatch, R. Knox): at 8.30 P.M.  
*Address:*

Professor W. M. Bayliss, F.R.S.: The Origin of the Electric Currents led off from the Human Body.

#### MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

**MONDAY**.—8.30 P.M.: *Paper*:—Major Sir Robert Armstrong-Jones, R.A.M.C.: The Psychology of Fear and the Effects of Panic Fear in War Time.

**RUMINIAN SOCIETY**, at the Royal Society of Medicine, 1, Wimpole-street, W.

**WEDNESDAY**.—9 P.M.: *Paper*:—Mr. C. Heath: Diagnosis and Treatment in Otitis Media.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

**TUESDAY AND THURSDAY**.—5 P.M.: Lumleian Lectures:—Dr. G. A. Sutherland: Modern Aspects of Heart Disease. (Lectures I. and II.)

#### POST GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

**MONDAY**.—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

**TUESDAY**.—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

**WEDNESDAY**.—10 A.M.: Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

**THURSDAY**.—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

**FRIDAY**.—10 A.M.: Dr. Simson: Gynaecological Operations. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

**SATURDAY**.—10 A.M.: Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

#### NORTH EAST LONDON POST GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

**MONDAY**.—Clinics:—10.30 A.M.: Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M.: Medical Out-patients (Dr. T. R. Whipham):

Gynaecological Out-patients (Dr. Banister). 3 P.M.: Medical In-patients (Dr. R. M. Leslie).

**TUESDAY**.—2.30 P.M.: Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M.: Medical In-patients (Dr. A. J. Whiting).

**WEDNESDAY**.—Clinics:—2.30 P.M.: Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M.: Eye Operations (Mr. R. P. Brooks).

**THURSDAY**.—2.30 P.M.: Gynaecological Operations (Dr. A. B. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M.: Medical In-patients (Dr. R. M. Leslie).

**FRIDAY**.—2.30 P.M.: Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

#### THE THROAT HOSPITAL, Golden-square, W.

**MONDAY**.—5.15 P.M.: Special Demonstration of Selected Cases.

**TUESDAY**.—6.15 P.M.: Clinical Lecture.

#### ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures and Discussions on Public Health Problems under

War and After-war Conditions:

**WEDNESDAY**.—4 P.M.: Lecture IX.:—Dr. H. L. Collis: The Protection of the Health of Munition Workers. Dr. H. M. Vernon, Mrs. H. J. Tenant, and Mr. G. Bellhouse have promised to take part in the discussion.

### EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To the EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

### MANAGER'S NOTICES.

#### VOLUMES AND CASES.

VOLUMES for the second half of the year 1916 are now ready. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half-year's numbers (inland edition) are also ready. Cloth, gilt lettered, price 2s., by post 2s. 4d.

To be obtained on application to the Manager, accompanied by remittance.

#### ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8d. The rates of subscription remain as revised in October.

#### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

#### TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscription given on page 6.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

## METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

## The Lumleian Lectures

ON

### MODERN ASPECTS OF HEART DISEASE.

Delivered before the Royal College of Physicians of London

By G. A. SUTHERLAND, M.D. EDIN.,  
F.R.C.P. LOND.,

PHYSICIAN TO THE HAMPSTEAD AND NORTH-WEST LONDON HOSPITAL;  
PHYSICIAN TO THE PADDINGTON GREEN CHILDREN'S HOSPITAL.

#### LECTURE I.

Delivered on March 15th.

MR. PRESIDENT AND GENTLEMEN.—The pleasure with which I received the great honour of an invitation to deliver these lectures was considerably diminished by the difficulty in selecting a subject. Even when a subject was selected the further problem arose as to how it was to be dealt with. In this dilemma I turned to one of my distinguished predecessors, Sir Douglas Powell, who said: "It is one of the functions of the Lumleian lecturer to review from the side of experience and clinical observation the net results of most recent researches, and to show how far they should influence us in our daily practice." This is the one and only function which I shall attempt to perform in considering some modern aspects of heart disease. Perhaps you will kindly make allowance for the difficulties which surround any attempt to do justice to such a subject at a time when other thoughts and other occupations fill our days.

#### RECENT ADVANCES IN CARDIOLOGY.

To many of us it has been made clear that within recent years there has been a revolution in the domain of cardiology—not a destructive revolution but a constructive one. It has really consisted in the filling-in of many gaps in our previous knowledge. Just as our predecessors were hampered by these gaps, so their completion has led to a great advance in our understanding of the subject. Exact knowledge has led to more accurate clinical diagnosis and to better therapeutic results.

Naturally there were pioneers in this work. It must be a matter of satisfaction to all in this country to recognise that British workers have been the chief pioneers. The two names that appear to me most entitled to honour are those of W. H. Gaskell and James Mackenzie. The physiological work of Gaskell gave to us much information as to the mechanism of the heart beat, the various functions of the cardiac muscular tissues, and the effects produced on them by injury or electrical stimulation. Gaskell thus fashioned the key which was to unlock the door to many cardiac problems. The key, however, lay unused until Mackenzie after strenuous work succeeded in fitting it to the lock. Probably there is no better example of the valuable assistance which experimental physiology has given to clinical medicine than the combined work of Gaskell and Mackenzie. All present workers in the field of cardiology must acknowledge their indebtedness to these two scientists, who not only laid the foundations but raised a superstructure to which comparatively little has been added.

#### The Functions of the Heart.

It must be admitted that the additions to our knowledge of the physiological and pathological action of the heart have greatly increased the complexity of the problems which are presented clinically. Roughly, we may say that the problems as viewed by our predecessors were concerned with the heart as a simple organ, with one function—contractility, and with two supplying nerves—the vagus as a depressor and the accelerans for stimulation. Now we have to deal with the heart as an organ of four chambers and four walls, and the action of each of the four muscular walls has to be differentiated as far as possible. This has not been finally accomplished, but by means of the polygraph and the electro-cardiograph Mackenzie and Lewis have made wonderful progress in this differentiation. The functions of the heart to be considered, in addition to contractility, are rhythmicity, excitability, conductivity, and tonicity. Formerly these were physiological terms merely, associated

with experimental work, but not bearing on clinical medicine. Now these functions are investigated at the bedside and their disturbances have come to occupy a most important place in connexion with diagnosis and treatment. The vagus and accelerans nerves are not directed to the heart as a whole, but seem to exercise a controlling influence on each of the functions of the muscular tissue of the heart, so that the specialised tissues for contractility, conductivity, excitability, rhythmicity, and tonicity may be regarded as under nervous influence.

As we study the discoveries which have been made as to the extreme complexity of the cardiac mechanism we are led to ask how this machine is controlled and how far it can be influenced by human interference. The physiological working of the heart suggests that it is an automatic organism, self-starting, self-acting and effective in carrying on the circulation. Even in diseased conditions we see the power of the heart to overcome difficulties in its own way, as in the case of valvular lesions. How little influence our therapeutic measures have in the compensatory changes which the heart develops in the presence of a valvular lesion! By reason of its automatic action the cardiac machine is also protected from many of those disturbances to which other organs in the body are subject. It may be a matter of consolation to some of us when we think of the large amount of "cardiac stimulants" and "cardiac tonics" which, with misdirected energy, we have levelled at the heart, it may be a consolation to think that after all they never reached the heart and never disturbed its automatic action. This point of view, that the heart in health and disease is an automatic organ very capable of doing its own work if undisturbed, may prove of some use in regulating our therapeutic measures.

As regards the exact amount of regulation or control which is exercised over the heart by the vagus and accelerans nerves our information is still very incomplete. A useful simile is that which compares a horse and its rider with the heart and its nerve-supply. A horse can go on very well without its rider, but with a rider its actions are controlled and regulated if necessary. It has been shown that it is not the heart as a whole that is under the control of the vagus, but the individual functions of the heart. So that not only have special areas of the cardiac muscular tissue developed special functions for the harmonious movement of the heart, but these areas, or the functions of these areas, have also been placed under nervous control. One may assume that circulatory difficulties in the heart (for example, valvular) or in the circulation (for example, arterial) may be met successfully by the automatic cardiac mechanism. But disturbances also reach the heart from without and through the nervous system. For instance, in the case of excitement the heart-rate is at once increased. It may be suggested that in such cases the controlling nerves of the heart step in and regulate the functions, so that the successful carrying on of the circulation is not interfered with.

#### The Chambers of the Heart : Junctional Tissues.

In former times and for clinical purposes the heart was viewed as consisting of two parts, the right heart (right auricle and ventricle) and the left heart (left auricle and ventricle). In connexion with diseased conditions the terms "right-sided failure" and "left-sided failure" were in common use. Clinically it will be found that a better division of the heart would be into an auricular part (the two auricles) and a ventricular part (the two ventricles). The auricles work together, suffer together, give rise to disturbances together, and fail together. Similarly the ventricles act together. While under conditions of health the auricles act as aids to the ventricular functions, in diseased conditions they may seriously hamper those functions. There is a third portion of the heart of great clinical importance known as the junctional tissues. This is a bridge between the auricles and ventricles formed by the auriculo-ventricular node and the auriculo-ventricular bundle. It aids the cardiac mechanism when the auriculo-ventricular action is harmonious, and it tends to control the effects of the disturbance when the action is not harmonious.

There is one further distinction to be recognised in the muscular tissues of the heart—namely, between those whose function is primarily and essentially that of contraction, and those differentiated for the purpose of excitability, impulse discharge, and conductivity. Commencing at the sino-auricular (S.-A.) node, extending over the auricles (by a path

not yet defined),<sup>1</sup> forming the auriculo-ventricular (A.-V.) node and the auriculo-ventricular (A.-V.) bundle, we find a continuous strand of differentiated muscular tissue dealing with these special functions and not with contractility. As the branches of the auriculo-ventricular bundle penetrate to the remotest parts of the ventricles they are in a sense part of the muscle of the ventricles. But in the main function of the ventricles—contractility—they take no part. So that when we speak of supraventricular tissues clinically we include the auriculo-ventricular bundle as it takes no part in the muscular contraction of the ventricles.

#### *Estimation of Importance of Cardiac Lesions.*

It is useful in the case of an organ like the heart, which is subject to various diseases and disturbances, to have some standard by which to estimate the importance of the cardiac lesions. In the past attention has been largely concentrated on valvulitis as the predominating disease of the heart, and on murmurs as the evidence of valvular lesions. Students learned to classify cases according to the valve affected, mitral disease, aortic disease, &c., and proceeded later in their practice to carry out the treatment indicated in the text-books for the form of valvular disease present. It may be said that the best writers and teachers held no such limited views. References will certainly be found to changes in the myocardium, to dilatation and hypertrophy, and to irregularities of the heart. These, however, occupied a very subsidiary place, and the effect of their teaching and writing was to impress permanently on the student the idea that valvulitis is the important lesion in organic heart disease, and that prognosis and treatment are to be based on the valvular lesion present.

The fact that the heart is essentially a muscular organ, a force-pump, has long been recognised, but it is only recently that the great importance of disease of the myocardium has been emphasised. Heart disease may be summed up as a disturbance of the driving power of the cardiac muscle. Attention therefore may well be directed to the effect which disease processes have on the heart muscle. Gaskell and other physiologists have been struck by the wonderful mechanism by means of which any irregularity of heart beat experimentally induced is more or less corrected before the ventricular contraction occurs. He found that the main factor in the maintenance of cardiac efficiency is the securing of a regular ventricular beat. We may apply this in clinical medicine and say that the effect of cardiac disease is to be estimated by the extent to which ventricular action is affected. In disease we find that the action of the auricles can be dispensed with without failure of the circulation, and as regards the right ventricle any weakness there is chiefly of importance because of its effect on the action of the left ventricle. So we reach the conclusion that whatever the disease or disturbance present the important point to be considered is its effect on the driving power of the left ventricle.

In dealing with cases clinically, a standard such as this—the amount of interference with the action of the left ventricle—will be found useful in connexion with all forms of structural disease, valvular or myocardial; with all irregularities associated with myocardial changes; with all excessive changes in rate, be it very much increased or very much decreased; with the subjective symptoms and objective signs of cardiac weakness and cardiac failure; and very especially in connexion with the whole question of treatment. It may be said that our knowledge of the exact processes of disease is not yet full enough and precise enough to allow of the adoption of any such standard. But it is the recent advances in our knowledge which have made such a standard possible. It is the precision of knowledge gained through such instruments as the polygraph and electro-cardiograph, which has made possible the recognition of many influences, hitherto unsuspected, which act upon, and interfere with, the ventricular contractions. Of this examples will be given later. No doubt further progress will be made on the same lines, but it is useful meantime to have a working standard which will not play us false.

#### *VALVULITIS AND VALVULAR LESIONS.*

The view that valvulitis is the central factor in heart disease has proved misleading. Attempts were made to

<sup>1</sup>"The exact morphological connexion between the sinus node and the auriculo-ventricular node has not been definitely established" (Wiggers).

explain cardiac failure on a valvular basis by means of theories, supported often by great authorities, but not supported by much evidence. The theory of back pressure was held to be the explanation of cardiac failure in such different lesions as mitral stenosis, mitral regurgitation, and aortic regurgitation. The common signs of cardiac failure are familiar to all—namely, great dyspnoea, cyanosis, oedema, engorged liver, and oliguria. The explanation given was that the blood was either dammed back (mitral stenosis) or thrown back (mitral regurgitation), and that great back pressure in the venous circulation resulted. Hence came failure of the right side of the heart and also the so-called "failure of compensation."

In this connexion it is to be noted that all the phenomena of cardiac failure from "back pressure" can arise and do arise when a previously healthy heart is affected with the condition known as paroxysmal tachycardia. The valves may be normal, the myocardium may be healthy, but if the attack is sufficiently prolonged all the phenomena of "back pressure" may develop.

It is also to be noted that similar signs of heart failure may appear in many forms of chronic heart disease in the absence of any valvular lesion. The condition may end fatally, and after death no trace of valvulitis is to be found.

Further, we find clinically that urgent symptoms of cardiac failure may arise suddenly in cases of valvular disease without any apparent cause. The common and typical example is the development of auricular fibrillation in mitral stenosis. Here there is no sudden increase in back pressure, no alteration in the state of the diseased valve, but there is a sudden alteration in the rhythmic action of the heart which seriously affects the action of the left ventricle.

It is also to be observed that in the case of the gradual development of signs of cardiac failure in chronic valvular disease there is no evidence that the "back pressure" has been increased, or that the valve has become more inefficient. After 10 or 20 years the giving out of a heart with valvular disease is to be traced to something different from back pressure. Surely, if all the phenomena formerly associated with "back pressure" and the presence of valvulitis may arise when there is no back pressure and no valvulitis, some other explanation of the origin of these phenomena is called for.

The really important factor in all these cases would appear to be that the driving power of the left ventricle has given out, or that its efficiency has been interfered with by some superadded complication. It may be exhaustion from overwork, or from a defective blood-supply, or from the development of an abnormal rhythm, or from a great increase in rate. In all cases the signs of cardiac failure are brought about by a diminution of the forward pressure exerted by the left ventricle, and not by any form of increased back pressure. Such an explanation will at least meet most of the difficulties which the "back pressure" theory left unsolved. In using the term failure of compensation, which formerly had rather a hazy meaning, we ascribe the failure to the left ventricle, and we do not rest satisfied in the matter of diagnosis until we make out why it is that the ventricle has been rendered less efficient as a contractile organ.

Another point about valvular lesions, which are to be recognised by the accompanying murmurs, is that these murmurs may disappear or be replaced by others, or be much modified under certain conditions associated with cardiac failure. If the heart is beating rapidly an aortic regurgitant murmur may become inaudible for the time being. If the left ventricle is much dilated there may be audible only one murmur, that of mitral regurgitation, and this may be dependent on dilatation and not on disease of the mitral orifice. Perhaps the most striking example is the disappearance of the presystolic murmur of mitral stenosis when auricular fibrillation develops. The conditions under which the murmur or murmurs may disappear are often those which lead to the development of severe cardiac symptoms and the call for medical help. So that the physician who is dependent on valvulitis as his criterion will find that his guide has failed him at the critical moment.

None the less valvular lesions are sufficiently serious in themselves, and sufficiently important from a diagnostic point of view, to demand careful study. Our object is to determine not only what valvular lesion is present, but what

effects of the lesions the patient is suffering from. The effects will be found very closely associated with the reaction of the lesion on the ventricles, sometimes the right ventricle, but much more frequently the left. Suppose that an aortic regurgitant murmur is heard. This denotes a reflux of blood into the ventricle after each systole. The murmur may be loud, but the reflux may be small. If we find no change in the size or impulse of the left ventricle, we are justified in assuming that the reflux is small in amount. The pulse will not be collapsing and the blood pressure will not be raised in systole and lowered in diastole as a result of the valvular lesion. Suppose, on the other hand, we find a collapsing pulse, and a high systolic blood pressure with a low diastolic pressure, as a result of this aortic lesion, we shall expect to find evidence of dilatation and hypertrophy of the left ventricle, and finding that we shall conclude that the amount of blood regurgitated is considerable. Similarly, the symptoms complained of by the patient, and any limitation of his cardiac response to physical exertion, must be carefully weighed in estimating the importance of a valvular lesion.

#### DISORDERED ACTION OF THE HEART.

The old views as to cardiac irregularity have been entirely replaced owing to new methods of investigation and the precise information gained through them. The possibility or, as we now know, the fact that the signs of cardiac weakness and failure might follow as the result of the irregularity does not seem to have presented itself until recently. Thus Balfour states: "Associated with any other valvular lesion irregularity must always be regarded as a symptom of cardiac failure." It was noted that in cases of cardiac failure from any cause an irregularity of the pulse was often present. It was further noted that many cases of severe cardiac failure showed a markedly irregular pulse and heart beat. From these observations the conclusion was drawn that in all cases cardiac irregularity was to be regarded as an indication that the cardiac power was failing, whether the disease was a general one, for example, typhoid fever or pneumonia, or one primarily affecting the heart, for example valvular disease. The irregularity was supposed to involve the whole cardiac action; there was no knowledge as to any precise localisation of the irregularity in the heart or as to the underlying changes in the myocardium.

The explanation of the uncertainty was not far to seek. To physicians symptoms are the clues of hidden disease, and the successful working up of clues is a powerful aid in diagnosis. On the other hand, a symptom which is not understood is a clue which leads nowhere, or possibly leads into error. Explanations were attempted as to the cause of the irregularity. Broadbent found that irregularity was the distinguishing feature of the pulse of mitral regurgitation. His explanation of the irregularity was the varying pressure to which the heart is subjected in inspiration and expiration, and the varying supply of blood to the ventricle thus induced in the presence of mitral regurgitation. It is interesting to compare these views with those of Balfour. The latter says:—

Like all other cardiac cases, those with mitral stenosis come to us as patients when compensation fails; an early result if not also a cause of this is defective nutrition of the myocardium, and as a consequence irregularity of the heart's action and of the pulse, more marked in this form of cardiac affection than in any other, and often amounting to a veritable delirium cordis.

We have now reached the stage at which the great majority of cardiac irregularities have been analysed and classified. The special types can be demonstrated by means of the polygraph and the electro-cardiograph. Irregularities which have no significance or importance can be separated from those which have both significance and importance. These are great advances from the student's point of view. What seems to be the chief discovery is that certain irregularities are directly responsible for an increased rate of the heart and an inefficient heart beat, from which signs of cardiac failure follow sooner or later. The heart is usually affected with disease previously and the irregularity follows, but the irregularity is the cause of such a disturbance in the cardiac functions that the previous lesions may be entirely obscured and fresh symptoms develop. Some irregularities, on the other hand, are of no significance or importance as regards the cardiac functions. If we wish to form an

estimate as to the importance of a cardiac irregularity we can employ as a standard the effect it has on the driving power of the left ventricle. We can observe, when an irregularity develops, the appearance of fresh cardiac symptoms, of changes in the heart itself, and it may be of progressive heart failure under the continuance of the irregularity. On the other hand, we can observe the return of the heart to its previous condition and the disappearance of the added symptoms when the irregularity ceases. In the field of therapeutics we have also to deal with irregularities, and a wide sphere of usefulness is now open for the employment of remedies in checking the injurious effects of irregularity on the action of the left ventricle.

In the past, clinical records of cases in the hospital wards or in publications frequently contained the words "the heart was irregular" or "the pulse was weak and irregular." The fact was noted, and if any inference was drawn it was to the effect that the irregularity was a bad sign. Now we expect an observer to state what form of irregularity is present, and to designate its probable site of origin, and to form an opinion as to the significance to be attached to it. For this purpose I should like to urge strongly that all students should be taught how to use the polygraph and the electro-cardiograph in the analysis of cardiac irregularities. They may not be able to possess them in their practice later on, but, speaking generally, they will be able to apply what they have already learned by using the ordinary bedside methods of examination. When once they have been able to take and study records from cardiac irregularities in cases under their own observation, they will have a much better mental realisation of the meaning and significance of these irregularities. In my student days we were taught the use of the sphygmograph, and many tracings were taken of different forms of irregularity. But the pictures were meaningless; we did not understand how the irregularity was produced or where it was produced, or what was its significance, if any. At the present time instrumental methods supply the key to these hidden mysteries, and a practical knowledge of these instruments will, I am convinced, be of lasting benefit to the medical student.

Disordered action of the heart may be of two kinds—namely, (1) disturbance of rhythm and (2) disturbance of rate. Either may be present alone or both may be present at the same time. Further, the rhythm of the heart may be disturbed without any interruption of the ventricular regularity, as is seen in cases of complete heart-block and auricular flutter, so that we may feel a regular pulse, listen to a regular ventricular beat, and yet be dealing with a case in which the rhythm of the heart is irregular and the irregularity is productive of definite signs of cardiac weakness. Again, the rate and regularity of the ventricular beats may be quite normal, and yet the auricular rate may be three or four times as great. This is seen in connexion with auricular flutter.

There are many forms of disordered action of the heart which were elucidated by means of graphic records. They seem complicated and have required a new nomenclature. Fortunately, they are often accompanied by distinctive clinical signs or symptoms, so that their recognition by ordinary bedside methods is steadily being rendered more easy.

There is a close interaction between disturbances of rate and of rhythm, so that the two might always be considered together in the clinical study of a heart case. An increase of rate or an irregular action is not necessarily an indication of a diseased heart; either may occur in a sound heart or in the functional disturbance of a sound heart. But in the case of heart disease of any type, presenting symptoms of cardiac failure, it may be said that some disturbance of rate or rhythm will very often be present. Further, it will usually be found that the symptoms of distress from which the patient is suffering are the result of this disturbance of rate or rhythm or, to be more precise, of the impairment of the functional activity of the left ventricle induced by the disturbance.

#### IRREGULARITY OF RHYTHM.

An irregularity of rhythm may be present without any injurious reaction on the heart, without, in short, any significance whatever. Of this class the commonest type is the sinus irregularity associated with respiration, in which the rhythmic discharge of impulses from the sino-auricular node is irregular. It is of no importance because it does not

affect the normal sequence of cardiac contractions in the different parts of the myocardium.

#### *Extra-systoles.*

Another form of irregularity may, under certain conditions, be considered as of no importance. An extra-systole is a very common irregularity in elderly people, who present no other indication of heart changes apart from those of old age. There is here a definite disturbance of the cardiac rhythm, occurring occasionally. The point of importance would seem to be that the extra-systole occurs so infrequently that the effect on the action of the left ventricle is negligible. Suppose it occurs every fifth beat when the heart-rate is 75. We shall then have 60 normal contractions per minute to 15 abnormal. The frequency of the abnormal contraction is not sufficient to disturb the efficiency of the ventricular action. Under these conditions therefore the presence of an irregularity may be of no significance, although under other conditions, that is great frequency of recurrence, the same irregularity may seriously disturb the cardiac action and power.

The extra-systole or premature contraction has been the subject of much study within recent years. It has been suggested by Lewis that such varied conditions as paroxysmal tachycardia, auricular flutter, and auricular fibrillation have as their pathological basis the same condition as that which gives rise to the solitary extra-systole. But the cause of an extra-systole is still to be found. It arises under such a multiplicity of conditions that one is led to wonder whether there is any pathological importance to be attached to the solitary extra-systole. It can be produced artificially in the laboratory; it is found in childhood and old age; it may be present in an otherwise healthy heart and in one which is diseased; it is associated with temporary nervous disturbance—for example, neurasthenia, with toxic conditions, and with the convalescent stage of many illnesses; it may occur only on exertion or only during rest, while the patient is standing up or only when he is lying down; and it may arise through the action of the vagus or through the action of digitalis. The list may be indefinitely prolonged. So far it has been determined that the extra-systole always arises at some abnormal spot in the heart—that is, not at the normal starting-place, the sino-auricular node. It is assumed by most writers that it is the result of an abnormal irritability, an increase of functional activity at some focus in the heart. This local overactivity leads to a premature impulse-discharge and contraction before the normal cardiac cycle starting at the sinus has begun. It may, however, be argued equally plausibly that there has been a depression of activity, a block in the conduction at some spot which, after a brief delay, initiates a contraction on its own. At present neither the one nor the other assumption can be proved or disproved.

#### *Auricular Fibrillation.*

There is no form of cardiac irregularity which is of more importance, both from its frequency and its gravity, than auricular fibrillation. It is interesting to note that when Balfour and Broadbent were discussing cases of extreme cardiac irregularity they were dealing with cases of auricular fibrillation. The serious symptoms associated with "failure of compensation" and "ruptured compensation" were clearly due to the same cause. The great benefit which followed the use of digitalis in heart disease was notably obtained in a certain type of case which we should now describe as auricular fibrillation. The facts are clearly shown in the clinical records of the past.

The clinical conditions which mark the onset of auricular fibrillation were noted, although not understood, by previous writers, and were found to arise most commonly in association with mitral stenosis. Certain stages in a case of mitral stenosis were accurately observed, and in the last stage peculiar features were commented on. For example, it was found that the second sound at the apex had disappeared. One explanation of this was that the enlarging right heart had so displaced the left ventricle backwards that the second sound became inaudible. Another fact noted was the disappearance of the presystolic murmur, and this was ascribed to the development of tricuspid regurgitation, and the diminished pressure in the pulmonary circulation and left auricle which followed. These facts as observed were correct, but the attempted explanations had rather an

academic interest because their bearing on the cardiac disturbances which accompanied them was not understood.

The recognition of the importance and frequency of the presystolic murmur, as described by Gairdner, was slow. The same may be said about auricular fibrillation. Yet auricular fibrillation is more than a name—it is a landmark in the advance of medicine. For the student the subject of cardiology will be rendered easier when he has watched and learned (1) the earlier stages of mitral stenosis, (2) the progress up to the onset of auricular fibrillation, (3) the clinical phenomena of auricular fibrillation; and (4) the results of its treatment by means of digitalis.

The history of the discovery of the condition now known as auricular fibrillation is worth repeating. A practitioner in Burnley—whom we now know as Sir James Mackenzie—had made out by means of his polygraph a method of recording the pulsation of the right auricle in what is known as a "jugular" or "venous" tracing. Under conditions of health and in many cases of disease this took a certain form showing definite waves or peaks. One of his old cases of mitral stenosis suddenly developed signs of heart failure, with extreme irregularity of the pulse. With this, as he had noted in other cases, the presystolic murmur disappeared. On taking a venous tracing he found that all trace of auricular contraction had also disappeared and that apparently the right auricle was not acting. Here, then, was the explanation of the disappearance of the presystolic murmur—the auricle was not contracting. The exact condition present was determined later, Cushing pointing out that the jugular and arterial tracings from dogs in experimentally produced auricular fibrillation resembled closely the peculiar jugular pulse and irregular rhythm in the human subject. Lewis proved later by means of the electro-cardiograph that the condition in the human subject was identical with the so-called auricular fibrillation in animals. I do not suppose that Mackenzie had at first any idea of the importance of his discovery, which has only been emphasised by subsequent work. In one thing he was singularly fortunate, for he had not only found the key to many previously unexplained cases of cardiac failure, but he had made it possible to employ digitalis with knowledge and with precision, a fact which he himself was the first to recognise and take advantage of.

For clinical purposes the two conditions of auricular flutter and auricular fibrillation may be considered together as being varieties of a disturbed action in the rhythm of the heart which have a common basis. In flutter definite although weak contractions, but of a different kind from the normal ones, are still taking place, while in fibrillation they are absent. In flutter the ventricular contractions may be regular or irregular for longer or shorter periods, usually they are regular; in fibrillation they are always irregular. In flutter the auricles may be contracting at the rate of from 150 to 300 per minute, possibly more; in fibrillation certain obscure muscular movements are detectable by the electro-cardiograph and are usually at the rate of from 300 to 600 or more per minute.

In connexion with chronic heart disease both conditions—fibrillation and flutter—tend to recur and finally to become permanent. In acute heart disease (rheumatic) an attack of either condition may be merely a temporary manifestation of active carditis. In acute and early heart disease flutter and fibrillation are rare, but some cases have been described, and even in quite young subjects. As a general rule flutter and fibrillation are associated with heart disease of some standing—for example, cases of mitral stenosis of considerable duration and of rheumatic origin or degenerative changes from cardiac sclerosis in elderly persons.

#### *Symptoms Associated with Auricular Flutter and Fibrillation.*

These two conditions, flutter and fibrillation, do not represent a form of heart disease, but a complication occurring in the course of heart disease. The normal rhythm of the heart has been disturbed, and the importance of the disturbance may be measured by the effect which the development of fibrillation or flutter has on the action of the left ventricle, and to a less extent of the right ventricle. The symptoms which follow are dependent on the response which the left ventricle is capable of making in the presence of this disturbing factor.

As a matter of clinical experience it will be found that in some cases the onset of auricular fibrillation will not be

characterised by any fresh symptoms which attract the patient's attention. In other cases, what the patient notices is the irregular action of the heart, without any added symptoms. In other cases the patient is conscious of increasing breathlessness on exertion or even at rest, and a marked limitation of his previous cardiac power. In other cases the disturbance of the cardiac action is sudden and profound, and the signs and symptoms are those of acute heart failure.

The nature of the symptoms which follow the onset of fibrillation or flutter will depend on several different factors. As already stated, the important point is, how does the left ventricle respond to meet the embarrassment caused by the new rhythm?

One factor of importance is the rate of the ventricular contractions which follows the onset of fibrillation. Unless some damage is present in the junctional tissue (A.-V. node and bundle) an increase in the rate of the ventricular contractions frequently follows, and the greater the increase the more marked will the symptoms of distress be. Thus with a ventricular rate of 150 per minute the symptoms will probably be more urgent than with one of 120. The importance of this increase may be assumed when we consider that a damaged heart, carrying on the circulation with more or less difficulty at a rate of 75 per minute, suddenly has its resting and recuperative period of diastole diminished by one-half, and its contractions doubled in number when the ventricular rate runs up to 150 per minute. The importance of this increase is demonstrated by the therapeutic results which follow from a slowing of the cardiac rate, as will be shown later.

A second factor which has to be considered is the irregular action of the ventricle. This irregularity is the result of the impulses proceeding from the auricles reaching the ventricles in an irregular manner owing to a disturbance of conductivity at the auriculo-ventricular node and bundle. The ventricle is filled irregularly, it is stimulated irregularly, and it contracts irregularly. There is thus a further loss of driving power and force, many of the ventricular contractions being so feeble that they cannot be recognised by feeling the radial pulse. While a regular rate of 150 beats per minute will tend in time to exhaust the ventricular force, a condition of exhaustion will be induced more rapidly when gross irregularity is superadded, as occurs in auricular fibrillation. It has seemed to me that the development of symptoms of acute heart failure is more common with fibrillation than with flutter, and this may be explained by the fact that although in the latter the ventricular rate may be as rapid, the element of irregularity is usually absent or much less marked.

A third factor is the state of the myocardium of the left ventricle at the onset of fibrillation. If the myocardium is healthy, or hypertrophied and powerful, the response will probably be good, and the symptoms not severe. If, on the other hand, the myocardium is much weakened by disease, the response will be less satisfactory. If the heart has been carrying on the circulation efficiently before the attack, although it has been diseased, then the disturbance which follows, although it may be severe at first, will probably yield readily to rest and treatment.

The clinical symptoms associated with the progress of auricular fibrillation were recognised 20 years ago. They were ascribed to cardiac failure, and it was noted that the pulse and heart were irregular. Now we ascribe the symptoms to the presence of an irregular rhythm of the heart—auricular fibrillation—and we can explain how the symptoms follow from this irregularity. Here is a description of the symptoms of auricular fibrillation by one of my predecessors which could not be bettered in the present day, although it was written for quite a different purpose.

When irregularity of the pulse is a marked feature, when a few beats are large and turbulent, to be followed by several small beats, when the pulse no longer corresponds in number with the cardiac contractions, when the heart itself shows signs of hypertrophy and extending dilatation of both ventricles with dullness extending upwards over the conus and left auricle, when the neck veins become full, fill from below and pulsate, the liver enlarges, the cellular tissue becomes dropsical, the lungs congested, and the urine scanty—with these symptoms and signs we have with increasing urgency the conditions calling for digitalis. (Sir Douglas Powell.)

#### *Acute Development of Auricular Fibrillation and Rapid Cardiac Failure.*

These chronic and progressive forms of auricular fibrillation are very common, and are recognised as such at the present time. I do not think that the acute development of auricular fibrillation and rapid cardiac failure is so generally recognised. One reason is that the cardiac conditions from the point of view of sounds and murmurs may be entirely obscured by the accompanying developments, as in the following cases.

A carman, aged 46 years, was admitted to hospital in a state of extreme respiratory distress. The history was that the same morning, about 8 o'clock, he had complained of a painful feeling of tightness in his chest. This was followed almost immediately by a difficulty in breathing, which gradually became worse until he was unable to move or exert himself in any way. The patient was breathing with extreme difficulty, unable to lie down, and the respirations were slow with prolonged wheezing expiration. The face and lips and hands were very cyanosed. The pulse was feeble and irregular, at the rate of 130 per minute. The heart sounds could not be heard owing to the loud rhonchi and rales which filled both lungs. The cardiac apex and the cardiac borders could not be determined. The liver was much enlarged. Various diagnoses were made as to the cause of his condition and to meet these the treatment was also varied. Venesection was performed to half a pint, and he received injections of morphine, atropine, strychnine, adrenalin, and ether, while brandy was given freely. I saw him six hours later, when his breathing was considerably easier. The pulse was of the grossly irregular type, beats of different strength being mixed up in a hopeless jumble. A pulse-tracing showed this well. A venous tracing could not be taken owing to the overaction of the neck muscles.

The history subsequently obtained was that he had had rheumatic fever 30 years previously, and had been discharged from the Navy 15 years previously because of heart disease. Since then he had been driving a two-horse van, a form of occupation sufficiently arduous. He had had no cardiac symptoms until three weeks previously, when, while lifting a heavy weight, he was seized with a severe pain across his chest and in the left arm, the power of which was lost. He recovered entirely in three days and resumed work, which he continued until seized with the present attack.

When the respiratory distress had quieted down it was possible to make out the cardiac condition. The rate had slowed down under treatment but the action was still irregular. The presence of auricular fibrillation was demonstrated by means of electro-cardiograph and polygraph tracings. The heart was much dilated and there were some powerful beats felt amongst many weak ones. The signs of mitral and aortic regurgitation were present. As is usual in such cases, rapid relief from all distressing symptoms soon followed after the heart was slowed, and the patient was able to be up and about.

There was little doubt that in this case the heart, although damaged by disease of many years' standing, had not shown any signs of actual failure until the sudden onset of auricular fibrillation. The symptoms of distress, taken along with the typical irregularity of the pulse, were sufficient to allow of a diagnosis being made. The condition of auricular fibrillation persisted during the following two years, after which the patient passed from observation. During this time the patient was always free from urgent cardiac symptoms when his heart-rate was controlled by digitalis.

A boy, aged 13, was a hospital patient owing to heart disease. He had had rheumatic fever at the age of 4½ years and on several occasions later on. He had been admitted to hospital several times because of shortness of breath and general weakness. The heart was greatly enlarged, on the left side especially, and the heaving action there suggested hypertrophy. The enlargement was ascribed to aortic regurgitation, a well-marked diastolic murmur being present at the base. The pulse was typically collapsing and the rate was from 100 to 110. After a short rest in the hospital he was usually able to take a moderate amount of exercise without discomfort.

On Nov. 14th, 1914, after running, he became very short of breath and complained of pain in the left side of the chest. He went home, and his mother noticed that he was very blue and cold. The breathing became worse and he was admitted to hospital. On admission he showed cyanosis, great dyspnoea, and anxiety. The dyspnoea was so great that a venous tracing could not be taken. A radial tracing showed a ventricular rate of 220 beats per minute, perfectly regular, and naturally a small pulse-wave. The cardiac condition determined was one of great dilatation, the apex

being in the seventh intercostal space 4 inches outside the nipple line. The right side of the heart was also considerably dilated. Over the whole praecordia a systolic murmur was audible. The liver was very much enlarged, the temperature was subnormal, and the respirations were 50 per minute. A short, hacking cough was very persistent and numerous rales and rhonchi were audible on auscultation. He was ordered digitalis.

Four days later he was somewhat easier but still suffering from dyspnoea and anxiety, but the cyanosis was less. The pulse-rate was 200, but for a short time during the day it had fallen to 100. The ventricular action was at times perfectly regular and at other times hopelessly irregular. Venous tracings suggested strongly a condition of auricular flutter when the heart's action was regular and of auricular fibrillation when it was irregular. He had taken ten doses of Nativelle's digitalin (gr. 1/240 sing.).

Ten days after admission the boy was free from all discomfort. The cardiac rate was 100 and the action was still irregular, the condition being one of auricular fibrillation. An aortic diastolic murmur was clearly audible and the pulse was collapsing. He had taken 18 doses of digitalin in seven days, when it was stopped because of vomiting. The signs of pulmonary and hepatic engorgement had passed off.

He remained a month in the hospital and was completely relieved of all acute symptoms. The auricular fibrillation persisted. A month later he was readmitted in a condition of acute cardiac failure very similar to the previous attack. The pulse was uncountable, but auscultation showed a cardiac rate of about 200, and very irregular action. On Jan. 12th the cardiac rate was 200. On the 13th, after three doses of digitalin, the rate was 120. On the 14th, after seven doses of digitalin, the rate was 84. On the 15th, after eleven doses of digitalin, the rate was 68. Vomiting occurred and the digitalin was stopped. With the slowing of the cardiac rate there came (1) the disappearance of all dyspnoea and anxiety; (2) the reappearance of the diastolic aortic murmur and the collapsing pulse; (3) no evident change in the size of the heart; (4) a clearing up of congestion in the lungs and liver. The auricular fibrillation did not pass off.

He was discharged on Feb. 2nd, quite able to take moderate exercise without discomfort. The advice given to continue his digitalis regularly was probably not followed. He was readmitted on July 12th in much the same condition as before, and died within a few hours. The autopsy records state: the heart is enormous; all the cavities are dilated; the ventricles are much hypertrophied; the pericardium is generally adherent; the mitral valve is much dilated; the aortic valve is incompetent.

Attacks of cardiac failure such as occurred in these two cases would have been described in the phraseology of former times as due to "broken compensation," and would now be described as due to "the onset of an abnormal rhythm," which in these cases was auricular flutter or fibrillation. The term "broken compensation" did not convey much information as to the cardiac changes, and so treatment was guided by the general signs and symptoms—an empirical treatment, even if often singularly successful. Now our treatment is directed to the cardiac changes, and more especially to the effect which these produce on the efficiency of the left ventricle, and the advantages of this will be considered later on.

I should like to go a little further and say that the term "failure of compensation" is actually wrong in such cases, because the compensatory changes have not broken down. Reference has already been made to the automatic action of the heart which maintains the circulation in the presence of valvular lesions, adherent pericardium, arterial disease, &c. The compensatory changes which have automatically taken place in the heart under these conditions do not break down at the onset of an abnormal rhythm like auricular fibrillation. They are there, and are still efficient if given suitable conditions for their action. This is shown by the fact that if the abnormal rhythm ceases or if its effects are removed by treatment the compensatory changes are found to be as efficient in carrying on the circulation as they were before.

**TAUNTON AND SOMERSET HOSPITAL.**—The annual meeting of the governors of this charity was recently held. The medical report was satisfactory. The financial statement showed that after appropriating legacies of £1310 there still remained an unfavourable balance of £2207. The committee regretted that Dr. A. E. Joscelyne had resigned from the honorary surgical staff. The Hon. H. E. Portman was re-elected president, and at the meeting he gave £1000 towards reducing the deficit balance of the hospital.

## ANTHRAX: SIMULATING CEREBRO-SPINAL FEVER.

BY R. J. REECE, M.A., M.D.CANTAB., M.R.C.S., D.P.H.,  
SURGEON-COLONEL, H.A.C.; ASSISTANT MEDICAL OFFICER,  
LOCAL GOVERNMENT BOARD.

(Report to the Medical Research Committee.)

Cerebro-spinal fever, now prevalent in various parts of the country, is to most of us a disease of which we have had little previous experience, and one that is so protean in its manifestations that it is not surprising to find that mistakes in its diagnosis frequently occur. Confusion as to its recognition may happen in illnesses accompanied by toxæmia associated with acute infective processes, or in certain acute cerebral diseases of primary origin and in meningitis due to causes other than meningococcal infection.

While, on the one hand, cases of cerebro-spinal fever have been mistaken for influenza, typhoid fever, pneumonia, measles, rheumatic fever, acute poliomyelitis, epilepsy, tuberculous meningitis, acute appendicitis, and other maladies; on the other hand, such diseases themselves have been regarded at times as cerebro-spinal fever. The following notes refer to five cases which were primarily thought to be cerebro-spinal fever, but which proved ultimately to be acute anthrax. The series is published at the request of the Medical Research Committee and with the consent of the Director-General, Sir Alfred Keogh.

Three of the cases occurred among soldiers and two among civilians, the former coming to my notice in connexion with the returns made to me of cases of cerebro-spinal fever among troops; for particulars of the civilian cases I am indebted to Professor S. Delépine and Dr. John Ritchie.

The number of cases in which the diagnosis of anthrax has rested on the examination of the cerebro-spinal fluid is, I imagine, very small. Dr. Ritchie has directed my attention to the fact that Pollak<sup>1</sup> appears to have been the first to describe such a condition.

**CASE 1.**—The first case in the series was that of a Yeomanry Lance-Corporal, aged 29, reported upon by Captain J. H. Beilby, R.A.M.C.(T.), the bacteriological investigation being carried out by Professor Walker Hall in connexion with the inquiry in regard to cerebro-spinal fever undertaken by him for the Medical Research Committee. The patient was in Camp C from April 27th to June 19th, 1915, and was away on leave from June 5th-7th at a farm at B. While in camp he slept on a ground sheet on the grass floor of a tent. On June 17th he complained of malaise and shivering; the next morning he had a temperature of 100° F. and a red catarrhal-looking condition of pharynx and fauces. On the 19th he woke in a state of delirium at 6.30 A.M. and at 6.40 A.M. was semi-comatose, semi-delirious, with signs of cerebral irritation, photophobia, a tendency to curl himself up and to burrow his head backwards, these symptoms persisting during the day. At 7 A.M. a copious involuntary action of the bowels occurred, consisting of loose faecal matter. At 8.30 A.M. there was another loose evacuation, the faeces being mixed with a considerable quantity of blood. A provisional diagnosis of cerebro-spinal meningitis was made. At 1 P.M. lumbar puncture was performed. The cerebro-spinal fever fluid was clear and not under pressure. It contained neither cells nor exudate, and on arrival at the laboratory it was found to be unsuitable for examination. At 5 P.M. the temperature was 99.8° and the pulse 66, slightly irregular. There was photophobia, the pupils being equal and contracted. The head was not retracted, although retraction was present at 4.30 P.M. During the night the patient was restless and violently delirious. On June 20th he recovered consciousness, answered questions, passed urine at will, and recognised his father. He complained of headache and pain in the lower cervical region. During the day quiet delirium alternated with conscious periods. The bowels failed to act in spite of 1-grain doses of calomel every three hours and 2 grains at longer intervals. The pulse was slow and regular, the temperature remaining normal.

On June 21st the condition was similar, but the pain in the head and neck was still considerable. After an enema an action was obtained, the stool being free from blood and mucus. Late in the day the temperature rose to 101°. On the 22nd lumbar puncture yielded a small quantity of clear fluid, which was not under pressure and did not contain any exudate, cells, or organisms. No cultures were made. On the 23rd the temperature continued to rise,

<sup>1</sup> Pollak: Wien. klin. Wochenschrift, 1912, p. 1702.

reaching 103°. The general symptoms were the same, but the headache and cervical pain increased. At 6.15 P.M., when seen by Professor Walker Hall, the patient was semi-conscious, but when roused exhibited clear perception and appreciation of his surroundings. He showed slight retraction of the head and rigidity of the entire muscles of the back. The reflexes were a little exaggerated, and there was some increase in surface sensitiveness. Kernig's sign was doubtful, spots were not visible, the pupils were equal, and the ocular muscles acted well. Tache cérébrale could not be obtained; signs of cardiac or pulmonary lesions were absent. An opportunity to investigate the urine and stool did not occur. The following blood and other examinations were then made.

*Blood examination* (June 23rd).—The blood count showed 4,200,000 red corpuscles and 16,000 white cells. Hæmoglobin 60 per cent. The differential count yielded: polynuclears, 30 per cent.; eosinophiles, 2 per cent.; large mononuclears, 10 per cent.; small mononuclears, 8 per cent. The blood serum did not contain any agglutinins for paratyphoid A or B. Vaccination against typhoid had been carried out in January, 1915. *B. coli* were agglutinated 1 in 10, and 1 out of 7 strains of streptococci showed slight clumping in 1 : 25 dilution.

*Blood culture* (June 23rd).—Blood was transferred directly from the vein into various culture media. It was examined daily for seven days, but remained sterile.

*Lumbar puncture* (June 23rd).—Six cubic centimetres of yellow slightly blood-stained fluid were obtained in two sterile centrifuge tubes. It was not under pressure. Within three minutes a slight clot was formed. The contents of one of the tubes was used for film examinations. It did not show any exudate cells or any micro-organisms. The other 3 c.c. were used for cultural purposes. One portion was transferred to suitable media; the remainder of the fluid was injected into a mouse. Thirty hours later the mouse was dead and showed the classical appearance of anthrax infection, while the cultures of spinal fluid yielded a Gram-positive, spore-bearing non-motile rod, which grew anaerobically and aerobically, liquefied gelatine, and showed typically spiked outgrowth; on potato giving a growth at first white and later reddish brown; in broth growing without scum with a granular thready deposit and on plates and other media exhibiting definite colonies with outgrowing threads curving inwards again to the colony. A small dose of the culture from the spinal fluid was injected into a guinea-pig (250 grammes). The animal died in 20 hours. The characteristic oedema at the site of inoculation, serous haemorrhages, and enlarged spleen were all present. Cultures made from the area of infection, from the heart blood, and from the spleen all yielded pure cultures of anthrax bacilli. *Naso-pharyngeal swab* (June 23rd): A naso-pharyngeal swab showed Gram-positive cocci only. Films from naso-pharyngeal material did not disclose any phagocytosis of Gram-negative or Gram-positive organisms.

On June 24th the temperature fell a little and the cervical pain was somewhat less, but there was retention of urine. On June 25th the temperature fell further; at 3 A.M. the patient had an inclination to micturate, but was unable to do so. In the words of the orderly in attendance "he complained of feeling numb in feet, legs, and thighs, and could not lift his arms." At 7.30 A.M. the next day he coughed violently, then collapsed, and died at 7.45 A.M. A necropsy was not obtained.

*Remarks by Professor WALKER HALL.*—“Although vomiting was not present, the symptoms on June 19th were sufficiently suggestive to be considered by Captain Beilby and Lieutenant Wilkinson as indicating the presence of cerebro-spinal fever. There was no sign of cut, wound, or abrasion, or any local manifestations of anthrax. As it was not possible to arrange for a post-mortem examination, the original focus of entry of the bacillus could not be ascertained. The blood showed a definite polynuclear response to an acute infection, although it did not yield a growth of the organism at the time of culture. Apparently it had passed out of the blood for the time being and was localised in the cerebro-spinal canal. Because of the unusual occurrence, the whole of the technics adopted were rigidly subjected to the closest scrutiny and criticism; there seems to be no doubt, however, of the presence of the *Bacillus anthracis* in the deeply yellow-coloured cerebro-spinal fluid. Once this is accepted, the symptoms may be accounted for by the occurrence of pia-arachnoidal haemorrhages similar to those which have been described in connexion with fatal cases of anthrax infection. The origin of the infection was not defined. In the district which the patient visited from June 5th to 7th, cases of anthrax have not occurred. The man had not been on duty in the horse sick lines, and his own horse was well. The lack of examinations of blood, urine, &c., owing to the early death of the patient makes this record incomplete, but it

may serve as a purpose in directing attention to the possibility of similar cases.”

As this was the first of its kind to come under notice the case was submitted to close investigation. It is a matter for regret that no post-mortem examination was obtained, and that the materials sent to Professor Walker Hall up to June 21st were not suitable for examination other than microscopic. The sterility of the blood and the presence of anthrax in the cerebro-spinal fluid were conditions so unusual as to call for rigid examination of any possible or probable source of fallacy. The only recorded case of anthrax in the neighbourhood was that of the cow on a farm 12 miles from the camp where the man was stationed. This case was seen by the local veterinary inspector, and his diagnosis of anthrax was confirmed by the Board of Agriculture and Fisheries. No material from this cow or from elsewhere at this time was examined at the Bristol University Laboratory. It was not possible to establish any connecting circumstance between the soldier's attack and this cow.

The only anthrax at the laboratory was a culture kept among the stock cultures in a special room and not touched save for reinoculation on the first of each month.

The patient died a few hours before Professor Walker Hall established the diagnosis, and the death was returned as due to cerebro-spinal fever.

**CASE 2.**—Lance-Corporal R. P., aged 22, Royal Engineers, was stationed at Fenny Stratford, Bucks. He was on stable picket on May 19th, 1916, and on the 20th came to London and was billeted in a northern suburb. From the 22nd he was one of a class of about 30 men under instruction in signalling at the G.P.O., Aldersgate-street. On the 25th he felt cold and went to bed complaining of pain in the left side of his chest. He slept well, but remained in bed on the 26th, the pain in the left side having extended to the left shoulder, but on the whole he felt better. On the 27th at 4 A.M. he suffered from frontal headache and still complained of pain in the left side. At 5.15 A.M. he was seen by Dr. Bremner, a local practitioner, who gave him medicine, which, however, he vomited. The same day he was removed as a case of cerebro-spinal fever to the isolation ward at the City of London Military Hospital, where he arrived in a state of coma and died the same evening at 9 o'clock.

Lieutenant W. J. Tulloch, R.A.M.C., military bacteriologist of the London Command, was asked to examine the patient with a view to determining whether the case was or was not one of cerebro-spinal fever. The man died at the hour of Lieutenant Tulloch's arrival at the hospital. The following account of the patient's condition was furnished by Lieutenant Tulloch:—

*Examination of the body.*—The body was that of a well-nourished man. There was no evidence of external violence. No deformities or recent sores of any kind were noted beyond a slight abrasion over the left patella. On Saturday, between 12 noon and 12.45 P.M., he is known to have fallen. Petechial haemorrhages were present over the upper part of the thorax, both anteriorly and posteriorly, also over the external aspects of the upper limbs, notably around the elbows. A few petechiae were also found on the extensor aspects of the lower limbs, notably over the quadriceps extensor muscles. These petechiae were dark purple in colour and averaged from one-eighth to a quarter of an inch in diameter. Lumbar puncture was performed and about 10 c.c. of fluid containing blood was drawn off. This material was taken to the laboratory at Millbank at once and was examined. Organisms having the morphological characters and staining properties of the *B. anthracis* were present in large numbers and a provisional report of “septicemic anthrax” was given by telephone to the medical officer in charge of the case. Cultural examination confirmed this finding, and a post-mortem examination was arranged for Monday, May 29th, at 12 noon.

*Post-mortem examination.*—1. General appearances: Beyond what is noted in the previous paragraph nothing of import was found. Special attention was paid to the question of the presence of malignant pustule, but exhaustive examination failed to show such a sore. 2. Thoracic organs: On opening the thorax the pleurae were found to be filled with clear straw-coloured fluid, about 20 ounces on the left side and about 30 ounces on the right. This fluid was shown on microscopic and cultural examination to contain *B. anthracis*. The pericardium contained about 7 ounces of similar fluid. The anterior margin of the left lung was bound by recent adhesions to the chest wall. No haemorrhages could be found on the pleurae or pericardium. Heart: The heart was normal in size and no valvular lesions were present, but the cardiac muscle was very flabby and showed cloudy degeneration. Some heart blood was drawn

off with precautions to ensure sterility. Microscopical and cultural examinations showed *B. anthracis*. Lungs: The left lung was dense and haemorrhagic, and on section its condition was seen to resemble that of "splenization." No alveolar air could be expressed from the cut surface, while inter-lobe adhesions united the lobes of the organ. The right lung was markedly hyperemic, but from its cut surface air and serous exudate could be expressed. The serous exudate was shown on microscopical and cultural examination to contain *B. anthracis*. The trachea and bronchi: The mucosa of the trachea and bronchi was deeply injected and very small submucous haemorrhagic areas were present. At the bifurcation of the trachea and in the larger bronchi there was present blood-tinted secretion, which on microscopical and cultural examination was found to contain *B. anthracis* and pneumococci. 3. Abdominal organs: The peritoneum was injected but no hemorrhages were noted. The spleen was large, weighed 15 ounces, and was dark in colour and flabby. On section it was found to be diffused. The spleen pulp was examined and found to contain *B. anthracis* in large numbers. These were recovered on cultivation. The liver was normal in size and colour, but showed evidence of commencing cloudy degeneration. The kidneys were normal in size, the capsule stripped easily, and a few subcapsular petechiae were found. On section these organs showed nothing of pathological import beyond evidence of cloudy swelling. The other abdominal organs also showed evidence of cloudy degeneration. The stomach: This organ was empty, and large areas of the mucosa were intensely congested and showed extensive submucous hemorrhages, notably towards the pylorus. Intestine: The upper part of the intestine showed no evidence of pathological change. Careful examination was made to exclude the possibility of the case being one of gastro-intestinal mycosis. The bladder: This organ was full and it was decided as a point of scientific interest to examine the urine. It was found to be sterile. The cranial cavity: This was not opened, but a cervical puncture was performed. Again blood-stained fluid containing *B. anthracis* was obtained.

**Summary.**—(a) Evidence of general septicæmia; anthrax bacilli isolated from pleural exudate, bronchial exudate, spleen, heart blood, and cerebro-spinal fluid. (b) Widespread, haemorrhagic consolidation of the left lung with deep injection of tracheal and bronchial mucosa; some hyperemia of the right lung. (c) Great enlargement of spleen. (d) Deep injection of, and submucous hemorrhage in, the gastric mucosa. Absence of definite evidence of intestinal mycosis. (e) Cerebro-spinal fluid haemorrhagic and contained *B. anthracis*.

**Conclusions.**—1. The cause of death was septicæmic infection with *B. anthracis*. 2. There is no evidence that the route of infection was by way of the skin, or gastro-intestinal mucosa. There was, on the contrary, evidence that the infection was primarily bronchial.

**Report of histological examination of internal organs.**—1. Lung: This organ shows a haemorrhagic broncho-pneumonia. The alveoli in the affected parts are filled with blood. Over the pleural surface there is a haemorrhagic deposit. Sections stained to demonstrate organism reveal the presence of *B. anthracis* in large numbers within the alveoli and along the lymph capillaries, while neighbouring blood capillaries are seen to contain but few bacilli. 2. Gastric mucosa: The haemorrhagic condition of the mucosa is found to be submucous, and few organisms are found within the capillaries. The epithelium around the haemorrhagic patches is necrosed. 3. Heart: The cardiac muscle shows definite evidence of pigmentary degeneration and cloudy swelling. Few bacilli are seen within the capillaries. 4. Kidney: The epithelium of the tubules shows extreme cloudy degeneration amounting to complete necrosis in certain areas. The cells of the vessel walls and of the glomeruli do not exhibit this change to the same marked extent. Numbers of bacilli are seen both in the capillaries of the inter-tubular vessels and in the glomerular tufts. 5. Liver: This shows marked cloudy swelling. The organisms are easily demonstrated. 6. Spleen: Good preparations of this organ could not be made owing to its being diffused. These findings corroborate the observations made at post-mortem examination, and the distribution of the organism in the lung points to the case having been one of definitely primary bronchial infection.

None of the people in the house where the patient was billeted had anything to do with hair, hides, skins, horses, or cattle. He slept on a flock mattress with a feather-bed on the top of it. The floor was covered with linoleum and there were no hair or skin rugs in the room. Stable picket-duty would involve going into the stable, but it would not be necessary for the picket to handle the horses unless the animals were restive or ill. No horse sickness was reported at Fenny Stratford nor in the neighbourhood.

In this case *B. anthracis* was recovered from the cerebro-spinal fluid and from the heart's blood and spleen, as well as

from the pleural and bronchial exudates. It was clearly a general septicæmia. Beyond the abrasion over the left patella no recent sore of any kind was discovered; the shaven part of the face was carefully examined for traces of skin lesion. In the absence of any abrasion or lesion of the skin, and in view of the microscopical and histological post-mortem findings Lieutenant Tulloch came to the conclusion that the case was definitely one of primary bronchial infection. The patient's kit was removed from his billet and disinfected by the Islington sanitary authority. Examination of the articles showed that they had been sterilised and no satisfactory bacteriological examination could be made. The man's shaving-brush and razor could not be found; inquiry showed that these had been sent to the steriliser along with the other articles, but they were not returned.

As has been said, the source of infection in this case was not discovered.

**CASE 3.**—A Lieutenant-Colonel, aged 50, Canadian Army Medical Corps, who was in command of a military hospital near Aldershot, had not felt well for several days, the condition being regarded as ordinary catarrh or "influenza." During the morning of Jan. 3rd he seemed worse, but remained on duty until the afternoon. It was then noticed that the parotid region on the left side was swollen and a diagnosis of "mumps" was made. The swelling, however, increased very rapidly, so that by 5 P.M. the head was held over to the right. During the evening troublesome vomiting came on with acute abdominal and epigastric pain, and towards 11 P.M. the patient became drowsy. This drowsiness deepened to coma accompanied by convulsions, and with the idea that the case might be one of fulminating cerebro-spinal fever, a lumbar puncture was performed and blood-stained fluid obtained; the cerebro-spinal fluid was not under increased pressure. The patient died early in the morning of Jan. 4th.

Examination of smears of the spinal fluid revealed Gram-positive bacilli in chains and some Gram-positive cocci. This discovery raised the suspicion that the illness was due to anthrax. A post-mortem examination was made by Captain H. H. Scott, R.A.M.C., who found the following conditions.

**External.**—A small recently healed sore just in front of the anterior attachment of the pinna of the left ear; considerable swelling of the parotid region and of the neck adjacent to the left side, extending down as far as the clavicle. Incision into this swelling showed that the parotid gland itself was not affected, but the cellular tissue in and around it, the swelling being due to a dark bloody serum.

**Dissection.**—**Head:** The meninges congested with dark fluid. Thorax: Fluid in each pleural cavity; old adhesions at both bases. Small petechial spots over both pleurae, mainly on, but not confined to, the lateral aspects. The lungs showed nothing abnormal beyond the general dark serous staining. Heart and large vessels: Slight atheroma at the root of the aorta, no other abnormality, no valvular mischief; myocardium dark in colour; coronary vessels patent and a little rigid. Abdomen: The interior of the stomach showed several (10-12) ecchymoses, varying in size from that of a millet seed to a shilling, and about half of them surrounded a minute ulcer. The intestines at intervals, and especially the ileum, contained similar congested, ecchymotic patches, and occasionally ulcers the size of a pin's head, about six in all. Small extravasations were also present in the mesentery in four situations. Liver: Fatty and slightly enlarged. Spleen: Large and diffused. Pancreas: In this gland were a few minute whitish-yellow patches suggestive of fat necrosis, but not at all extensive and confined to the head. Kidneys: Right was enlarged, but showed no macroscopic abnormality. Left small and shrunken; this had been explored at an operation for perinephric abscess some years ago.

Cultures were made of the blood, of the cerebro-spinal fluid, and of the bile; and smears of the same fluids were also taken. The latter showed Gram-positive bacilli and chains of streptococci; the cultures all yielded a mixed growth of anthrax bacilli and streptococci. The anthrax bacilli were further confirmed by gelatine stabs, agar plates, and animal inoculation.

It would seem to be beyond dispute that the patient died from an acute attack of anthrax and streptococcal infection. Suspicion arose that he might have been infected by a shaving-brush. It was ascertained that the patient had purchased a new shaving-brush about three weeks before his illness. Cultures made from this brush were examined in the School of Army Sanitation at Aldershot and a guinea-pig was inoculated with the material. The *B. anthracis* was not shown to be present; the cultures contained mycoides. The guinea-pig died, but no trace of *B. anthracis* was discovered.

Two similar brushes, procured locally from the store at which the patient's shaving-brush had been purchased, were

examined by the military bacteriologists at Aldershot and at the Royal Army Medical College, Millbank, with the following results. At Aldershot the growth on agar was not typical of anthrax; broth became cloudy throughout; the gelatin stab was not characteristic, and produced gas; the bacilli were actively mobile, spores tended to be terminal, the bacilli had rounded ends, only grew in short chains, and were non-pathogenic to guinea-pigs in eight days. At the Royal Army Medical College a large number of cultures from the hair were attempted and three pure cultures of a spore-bearing bacillus which had some resemblance to *B. anthracis* were isolated and tested by intraperitoneal inoculations of guinea-pigs. The result of this part of the examination was negative. A considerable quantity of the remaining hair was thoroughly washed in sterile saline solution and the washings were injected into a guinea-pig. The guinea-pig died within 54 to 68 hours after inoculation with typical anthrax infection.

These examinations show that it is not an easy matter to determine the presence or absence of *B. anthracis* in the hair of shaving-brushes. Additional proof that infection was in all probability derived from the shaving-brush was obtained. The brushes in question were found to have been purchased at Aldershot from a middleman, who obtained them in December, 1914, from a London firm, to whom the brushes were being supplied from a factory to which other shaving-brushes infected by anthrax had been traced by Dr. F. J. H. Coutts, of the Local Government Board.

CASE 4.—Particulars of the bacteriological examination of this case are placed at the service of the Medical Research Committee by Professor Delépine.

J. O. L., aged 49, complained of feeling ill, shivered and had pain in the head on April 23rd, 1916; on the 25th the pain in his head was severe. At 11 A.M. on the 26th he sent for Dr. T. C. Somerville, of Waterfoot, who found that the patient had slight twitching movements from time to time. No definite diagnosis was made, but cerebro-spinal fever was suspected, and Dr. J. P. Brown, medical officer of health for Bacup urban district, was asked to see the patient in the evening, and this he did about two hours before the death, which took place the same night. Swabs from the naso-pharynx and cerebro-spinal fluid were taken post mortem on April 27th and submitted to Professor Delépine, of Manchester, for examination.

Professor Delépine found no micro-organisms resembling meningococci in the naso-pharyngeal swab. The specimen of cerebro-spinal fluid sent for examination consisted of about 5 c.c. of deeply blood-stained fluid, microscopical examination of which showed numerous red blood corpuscles, leucocytes, and large bacilli, but no meningococci. On culture growths having the characters of the anthrax bacillus were obtained on April 28th; and two guinea-pigs inoculated on April 27th died on April 28th with typical anthrax lesions from which pure cultures of anthrax bacilli were recovered. The patient worked at a felt manufactory and in his employment handled East India wool and cow hair. There was some exposure to dust from the wool but practically none from the hair, and the ventilation of the room was fairly good. The man was reported as being clean in his habits, but he used no overalls, gloves, or respirator, and he took his meals in the drying-room.

In this case the cerebro-spinal fluid, which was mixed with blood, was obtained post mortem and there is no evidence to show that the *B. anthracis* was present in the cerebro-spinal fluid before death. Professor Delépine, however, points out that *B. anthracis* is always found in the cerebral and meningeal vessels in cases of general anthrax. Although the man's occupation affords a clue as to the source of infection, the channel by which the disease was acquired was not ascertained. There were no external signs to indicate that the infection might have been acquired through the skin.

CASE 5.—The particulars of this case are placed at the disposal of the Medical Research Committee by Dr. John Ritchie, bacteriologist to the county of Dumfriesshire, and Dr. Mungo Bryson, of Thornhill.

C. E., aged 16, "glass-meat" worker, was seen by Dr. Bryson on the evening of Oct. 23rd, 1916. He complained of headache, chilliness, vague pains in back and legs, and of pain and swelling on the left side of the neck. He gave a history of having driven 28 miles in an open vehicle on the evening of Oct. 21st and of having been seized by chilliness and headache on his return home. His condition became worse during the following two days, and, when seen, he was evidently seriously ill, his temperature being 103° F., his pulse 108, regular, and full. The glands

on the left side of the neck were palpable, but not particularly tender. A small black scab was noticed beneath the angle of the left jaw. The patient, on being questioned, attached no importance to it, and did not know how it had been caused. The surrounding skin was perfectly healthy, showing neither inflammation, vesicles, nor any secretion. On the morning of Oct. 24th he felt rather better; temperature 101.6° F., pulse 108. The cervical glands were still painful, the throat showed no redness, and there was no skin eruption. During the night he was restless and complained of severe headache. When seen about 7.30 A.M. he was semi-conscious, but could be aroused by questioning. The pupils were equal, dilated, responded sluggishly to light, and there was slight nystagmus. Kernig's sign was present, but otherwise there was no spasm, tremor, or paralysis. Lumbar puncture was performed about 11 A.M. Approximately 10 c.c. of uniformly pink fluid, not under pressure, were drawn off. The fluid contained albumin and did not reduce Fehling's solution. About 5 ounces of urine were drawn off by catheter. It contained neither albumin nor sugar. During the course of the afternoon the patient had three convulsive fits and died about 3 P.M.

*Microscopic examination of cerebro-spinal fluid.*—Films made from the deposit showed great numbers of red blood corpuscles and a high leucocytosis, polymorphs and large mononuclear cells being present in a ratio of 3 to 2, roughly. The majority of those cells stained well, though a few large vacuolated cells in a degenerate condition were noted. In every field were large numbers of Gram-positive bacilli, morphologically identical with *B. anthracis*. These showed a great tendency to chain formation, chains of 15 to 20 rods being common. No other organism was detected. Cultures, aerobic and anaerobic, on blood agar and Löffler's serum showed after 18 hours a pure growth of typical anthrax colonies. Microscopically the organisms were identical with *B. anthracis*, and growth on ordinary media showed the usual anthrax characteristics save that "spiking" in gelatin stab was poorly developed.

A guinea-pig inoculated with a few drops of the washing from an 18-hours' blood-agar slope died within 30 hours. It showed the classical post-mortem appearances of experimental anthrax, and the bacilli were demonstrated in spleen, kidney, and pleural and peritoneal exudates.

A post-mortem examination of the body of C. E. was made on the evening of Oct. 26th. As it had to be rapidly performed at a late hour, and in a small country cottage, it was not practicable to make as extensive an investigation as might have been done in more favourable circumstances, but the following points were noted:—

Body well nourished. Post-mortem rigidity moderate. A small black eschar, about 0.5 cm. in diameter, beneath left jaw, showing appearances already noted. Otherwise no external evidence of disease. The left submaxillary gland seemed, on palpation, to be somewhat enlarged. Cranium: On reflecting the dura mater, which was of an intense purple colour, the pia and arachnoid were found to be exceedingly congested, all the vessels being distended and much extravasated blood filling the subarachnoid space. This hemorrhage covered the entire cerebral surface, and was most intense over the frontal and occipital bone. At no point, however, was the shape of the convolutions obscured by the extravasation, which was evidently of a less extreme degree than that occasionally found in similar cases (Bruce and Shennan,<sup>2</sup> Symmers and Wilson<sup>3</sup>). The cerebellum, pons, and medulla were comparatively little affected. The hemorrhagic condition appeared to be confined to the meninges, sections of the brain cortex showing nothing abnormal. Thorax: Beyond the fact that the lungs showed slight apical emphysema, and that there were some trifling pleuritic adhesions on the left side, there was nothing noteworthy in the thoracic cavity. Abdomen: The spleen was slightly enlarged, dark, and soft. The kidneys and liver showed cloudy swelling. The stomach was practically empty. It showed no sign of inflammation, nor could anything suggesting a primary focus of infection be detected in the bowel. There was no trace of peritonitis, and, except a few tubercular mesenteric glands, nothing else of note in the abdominal cavity. The left submaxillary gland showed, on section, a limited area of congestion. Cultures made from the spleen gave a mixed growth of *B. anthracis* and cocci. Cultures from the heart blood showed cocci. Sections of the brain and meninges, microscopically examined, showed extreme congestion of the meningeal vessels with much extravasation of blood. Enormous numbers of anthrax bacilli were present in the extravasation, lying chiefly around the vessels and in the subarachnoid space. Practically none were contained within the blood-vessels. There was no encephalitis. A considerable number

<sup>2</sup> Bruce and Shennan: Review of Neurology and Psychiatry, 1910 p. 521.

<sup>3</sup> Symmers and Wilson: Journal of Path. and Bact., 1909, xlii., 251.

of bacilli were found in the perivascular spaces of the cerebral substance, but here again the vessels themselves contained none. Sections of the eschar from beneath the jaw showed non-characteristic scar tissue. No anthrax bacilli could be detected. Sections of the submaxillary gland showed appearances suggestive rather of early tuberculosis than of any acute condition. No anthrax bacilli were seen.

Despite the negative results of the last-named examination, the presence of a skin lesion on the neck and the patient's complaint of pain in that neighbourhood seemed, in the absence of any other evidence as to the channel of entry of the infection, to require further investigation, although the possibility of a malignant pustule in this area aborting, healing spontaneously, and being followed later by an acute meningitis appeared somewhat remote. As the scar was within the shaving area the patient's shaving-brush was obtained for examination. The hairs were cut off, the handle broken up, the cement loosened, and the whole placed in sterile saline and slowly heated to 80° C. After cooling the liquid was strained through a loose plug of sterile glass-wool to remove solid débris, and then centrifuged. One or two loopfuls of the deposit were plated on agar, and the remainder suspended, and injected into the peritoneal cavity of a guinea-pig. The results were entirely negative.

In view of the fact that Elworthy<sup>4</sup> has shown that the examination of a shaving-brush suspected of having caused anthrax may give negative results, while other, unused, brushes of the same batch may show anthrax bacilli, we endeavoured to procure some other brushes from the dealer who had supplied C. E. This investigation led to nothing. C. E. had possessed his shaving-brush for a considerable time, and it was, in fact, doubtful whether he had procured it from the tradesman whose stock we investigated, or elsewhere. The only brush which resembled that used by C. E. was examined as described above, but again without result.

The fact that C. E. was employed in handling meat appeared to suggest the only other likely source of infection. The factory in which he worked deals with a large quantity of meat, much of it imported, and we could obtain no evidence of any meat of suspicious appearance having been used. No other cases of anthrax occurred among the workmen, and one would certainly have expected that, had anthrax-infected meat been accidentally used, some of the men who handled it uncooked would have been affected, rather than C. E. who worked with it only at a late stage of its preparation. Nevertheless, in the absence of any evidence of infection from other sources, the meat must rest under suspicion.

In regard to the absence of any demonstrable primary lesion the possibility of infection by the nose suggests itself. Risel<sup>5</sup> described a case of meningeal anthrax in which he claims to have demonstrated the passage of infection up the olfactory nerve, and points out that the direct communication which exists between the perineural lymphatics of the olfactory mucosa and the subarachnoid space gives opportunity to such a mode of spread. The infection in such a case would not necessarily be air-borne, it might be conveyed by the fingers.

The case described appears to indicate the desirability of performing lumbar puncture in all cases of meningitis of doubtful origin.—J. R.

The source of infection in this case was not traced. There is no evidence to show that the meat, handled by the patient in the course of his employment, and it was cooked meat, was infected by anthrax. Notwithstanding that careful examination of his shaving-brush failed to discover *B. anthracis*, yet as the patient had a small scar beneath the angle of the left jaw associated with pain and swelling of the left side of the neck, the possibility of infection having been acquired through the skin cannot be eliminated.

However the infection may have been acquired, the fact remains that the illness was regarded as suspicious of cerebro-spinal fever; and cerebro-spinal fluid, taken during life by lumbar puncture, was shown upon examination to contain *B. anthracis*, no other organism being detected.

## THE "LATENT PERIOD" IN ACUTE PERFORATIONS OF THE STOMACH OR DUODENUM.<sup>1</sup>

BY DENIS KENNEDY, F.R.C.S. IREL.,  
SURGEON TO ST. VINCENT'S HOSPITAL, DUBLIN; SURGEON TO THE CHILDREN'S HOSPITAL, DUBLIN, ETC.

ALTHOUGH a great deal has been written about acute perforation of the stomach and duodenum still the early diagnosis of the calamity is frequently missed. Not alone is an accurate diagnosis not made, but the fact that a grave intraperitoneal lesion has occurred is completely overlooked. This, I believe, is largely due to the fact that, contrary to what one would expect from reading the text-books on the subject, the symptoms in this condition are not progressive and the physical signs are not developed until comparatively late. In other words, two conditions arise—first, the perforation, and secondly, the development of peritonitis; between these two a varying interval may elapse which may well be called the "latent period." To illustrate this I cannot do better than give a short history, from many, of a couple of cases that recently occurred in my practice.

CASE 1.—A short time ago I was called to see a case, in consultation, about 50 miles from Dublin. I arrived there a couple of hours after receiving the message, on a Tuesday afternoon. The patient was a lady about 50 years of age who had enjoyed good health, unless for an occasional attack of dyspepsia, up to a couple of days previously. On the previous Sunday night she had a hearty supper at about 9 o'clock. She felt uncomfortable after this, but went to bed as usual and slept until about 4 A.M., when she awoke with violent pain in the abdomen, vomited, and felt intensely weak. Her doctor saw her at 9 o'clock on Monday morning. She then described herself as having some abdominal pain, or more discomfort than pain, but she was gradually improving and felt very much better than she had some hours previously. The patient and doctor were inclined to attribute the trouble to the supper taken the night previously, and the condition was not then regarded as very serious. All day on Monday her condition remained pretty much the same. On Monday night she got a grain of morphia hypodermically to produce sleep; this had the desired effect. On Tuesday morning, when the doctor again saw his patient, he got an unpleasant surprise. She looked badly, had a quick weak pulse, and her abdomen was markedly distended. He at once recognised that acute peritonitis was rapidly developing, and sent for me with a view of having operation carried out.

When I saw the patient early in the afternoon she was dying. All the symptoms and signs of diffuse peritonitis were then present. She lay on the back motionless, with the legs well drawn up; her breathing was altogether thoracic in character; her general aspect could not be worse. Her pulse was almost imperceptible and could not be counted, and her temperature was subnormal. She did not complain of pain and her mind was perfectly clear. Her abdomen was distended to almost bursting-point; she begged for something to be done for her. While I was discussing with her doctor the futility of operating the patient died.

Both of us were quite agreed that the cause of the fatality was gastric or duodenal perforation, probably the latter on account of the comparative absence of symptoms previous to the attack. The early diagnosis of the condition was entirely missed by as able a practitioner as there is in the provinces. He was completely misled by the condition of the patient when he first saw her, by her persistent statement that she was rapidly improving, by the complete absence of well-marked physical signs, and by the fact that she remained thus during the whole of his first 12 hours' attendance.

The second case occurred within a week afterwards, but fortunately had a very different ending.

CASE 2.—Miss \_\_\_, aged 22 years, was admitted to St. Vincent's Hospital on a Sunday afternoon about 5 o'clock. She was examined by the house surgeon, Dr. A. Courtney, who promptly diagnosed gastric perforation and sent for me, while at the same time he made preparations to have an operation carried out. Being Sunday I had some distance to get back to Dublin after receiving the message, but I saw her at 8 P.M. and got the following history. The patient had suffered from repeated stomach

<sup>4</sup> Elworthy: THE LANCET, 1916, i., 20.

<sup>5</sup> Risel: Zeit. f. Hyg. und Infektionskrankheiten, 1903, xiii., 381.

<sup>1</sup> A paper read at the Surgical Section of the Royal Academy of Medicine in Ireland.

trouble for some years and had received a good deal of medical treatment for the condition. She retired to bed on Saturday night in her usual health, but awoke on Sunday morning about 5 o'clock with violent abdominal pain. She vomited once and then almost fainted. After a couple of hours her symptoms practically passed off and she did not send for a doctor until 4 o'clock in the afternoon. She drank fluids pretty freely during the day. The doctor sent her unlabelled to St. Vincent's Hospital. On examination, about 16 hours after the attack beginning, her appearance was by no means bad; she did not complain of much pain, but felt decidedly uncomfortable. Superficially one would not think that she suffered from any grave abdominal lesion. She lay rather naturally with her legs fully extended; her breathing was by no means distressed and was not wholly thoracic; her pulse-rate was, however, suggestive, being from 110 to 120; her temperature was normal. Her abdomen was somewhat distended, and although tenderness was present, it was by no means well marked, and was principally above the umbilicus. There was almost a complete absence of rigidity of the abdominal muscles. Although one might miss the diagnosis, I had no hesitation in confirming Dr. Courtney's opinion.

*Operation.*—On opening the abdomen by incision to the right of the mid-line I found a large quantity of a greyish-green fluid everywhere present in the peritoneal cavity. I did not notice any free gas present. The visceral peritoneum was everywhere injected, I saw no pus and no sign of lymph formation anywhere; the intestines were generally distended but not to a great extent. After some time I located a perforation, into which I could put the tip of the index finger, at the extreme cardiac end of the stomach. To reach the perforation I had to prolong the incision right up to the ensiform cartilage. To close the perforation in this situation was by no means easy. By getting Dr. Courtney, who was assisting, to pull the liver upwards with one hand, while with the other he drew the stomach downwards, I was enabled to bring the site of the perforation better into view. I attempted to pass through-and-through sutures for closure, but they at once cut their way out. This was due to the large area of ulcerated and inflamed tissue surrounding the perforation. Consequently I had to close the perforation by sero-muscular sutures. These were interrupted in character and extended from well above the perforation to well below it. They were outside the ulcerated area, and by their insertion the ulcer was completely inverted and large surfaces of peritoneum were brought into apposition. I inserted only one row of these and no other means of closure was adopted. The cardiac end of the stomach was considerably narrowed in lumen when the sutures were tied, but no ill-effects seemed to follow. I removed the contents of the stomach that had escaped into the peritoneal cavity by gently swabbing with dry sponges. I used no douche, as is my invariable practice in all cases of peritoneal infection. Closure of the wound and providing for free drainage completed the operation. I placed a drainage-tube with gauze wick (1) between the liver and the diaphragm; (2) above the pubes; (3) one in each flank. These latter three I inserted by stab incisions, easily made when the abdominal wall is made to project from the inside on the finger or a forceps. During the operation and subsequently before she regained consciousness the patient received about 8 pints of normal saline solution administered under the breasts. The recovery was rapid and uneventful. No pus formation occurred after the operation.

The absence of pus or of purulent peritonitis either at the operation or subsequently is probably due to two or three causes. 1. The stomach was empty of food when the perforation occurred, consequently its contents were not highly septic. 2. The fact that the perforation occurred high up. I think we may take it as pretty certain that the more we descend in the gastro-intestinal canal the more septic the contents become. 3. The free drainage provided for at the operation. I am indebted to Dr. Courtney in this case for his prompt diagnosis, his able assistance at operation, and his after-care of the patient. I would emphasise the fact that when I saw her first, 16 hours after the perforation occurring, the symptoms were not severe and the signs of diffuse peritonitis were not at all very pronounced.

In both of these cases perforation occurred when the patient was asleep and when the stomach must have been free from food. This would point to the conclusion that auto-digestion plays a great part in the occurrence. To look at these cases of perforation from a proper standpoint we must remember that an interval varying in length elapses between the two acts of the tragedy—first the perforation, then peritonitis; and that for treatment to be successful our interference must take place before the second act is staged, or, at all events, before it is long in existence. Consequently early diagnosis is essential.

To simplify early diagnosis I consider it convenient to divide the course of events as regards symptoms and signs into three stages: (1) The stage of shock and collapse, (2) the stage of reaction, (3) the stage of diffuse peritonitis. One need only remember the sequence of events to see why each of these set of symptoms is brought about. The shock as well as the pain is altogether due to the injury which the peritoneum receives from contact with the stomach or intestinal contents. When the stomach is emptied, as it pretty quickly will be, by extravasation of its contents and by vomiting, the injury to the peritoneum ceases, until septic conditions develop. Unless the patient has received a knock-out blow reaction sets in, and the patient may be comparatively well sometimes for several hours. The length of time will depend on the degree of septicity of the contents escaped into the peritoneal cavity and on the amount. The development of peritonitis requires no explanation.

It is frequently during this time of reaction or latent period that the medical attendant first sees the patient after the attack has begun. Consequently his difficulty of diagnosis. He finds little on examination; the patient may look well, and usually asserts that improvement in his or her condition is decided. Symptoms are more or less in abeyance and physical signs are not yet well marked, and if the practitioner's knowledge of acute perforations has been derived from books and not from experience there is risk that the diagnosis will be missed. How, then, is the diagnosis to be made? The history of the case previous to the attack is of some value; the history of the attack itself is absolutely essential.

An acute attack of violent abdominal pain associated with severe shock and collapse, and followed by an improvement in the mind of the patient, is always significant. Add to this an increasing pulse-rate with a subnormal temperature and there is quite sufficient to warrant operative interference. Vomiting is not of much significance, as it may be absent in perforations, and it is present in so many other conditions.

Of course there will be physical signs elicited on a careful abdominal examination, but not so pronounced, as is usually believed, previous to the development of peritonitis. Great stress is laid on the rigidity of the abdominal wall. True, there will be rigidity present, but at this stage of the trouble it will be strictly confined to the area of the abdomen involved, and I have never seen it so marked that it could be described, as it often is described, as being "board-like" in character. Tenderness will also be confined to the region of the perforation, and no decomposition will have occurred either in the peritoneal cavity or in the abdomen to produce marked distension. So that during the "latent period" the diagnosis will have to be made (1) from the history of the attack; (2) an increasing pulse-rate without corresponding increase in temperature; (3) localised rigidity of the abdominal muscles; (4) localised abdominal tenderness; (5) beginning abdominal distension.

Fortunately, when the diagnosis is made there is no difference of opinion as to the essentials of treatment. These are altogether operative, with two main objects in view: to repair the lesion and to get rid of the foreign material from the peritoneal cavity. I always get rid of this material by dry sponging, gently used. I never douche, as I believe it does more harm than good, especially by bringing the infective material to the most remote corners of the abdominal cavity. Besides it takes time. I usually employ drainage, always when the soiling of peritoneum has been present for a few hours.

There is one other point about which a legitimate difference of opinion exists in the minds of surgeons. Should gastro-enterostomy be performed at the same time if there is indication that this procedure will be required later? Personally I am decidedly of opinion no, if it can be at all postponed. The further time required may turn the scale completely against the patient; besides, we are working in an infected area, and this is not conducive to good results. But in the last few weeks I had a patient from Mr. T. M. McEvoy, of Blackrock, with stomach perforation, in which I had to perform gastro-gastrostomy, and with the happiest results.

This patient had a perforation in the centre of a large ulcer on the anterior wall of the stomach about the junction of the upper and middle thirds. When I had the ulcer inverted the stomach was divided into chambers with only

## MECHANICAL SUPPORTS IN PLASTIC SURGERY.

BY H. D. GILLIES, F.R.C.S. ENG.,  
CAPTAIN, R.A.M.C.; CAMBRIDGE HOSPITAL, ALDERSHOT;

AND

L. A. B. KING, L.D.S. R.C.S. ENG.,  
CAPTAIN, ATTACHED R.A.M.C., CAMBRIDGE HOSPITAL, ALDERSHOT.

THE problem of the restoration of the contour of the face resolves itself into the provision not only of the fleshy covering, but also of the supporting substructure. It is the supporting framework with which we wish to deal in this paper, and we think its importance so great that too much consideration cannot be given to this subject by the plastic surgeon. In no other part of the work does the co-operation of the dentist and surgeon come more fully into play. Failure to provide a suitable substructure is, in our opinion, the commonest cause of plastic failures.

We hope very much by the illustration of certain types of case to prove the value of combined work. Exigencies of space prevent more than two cases being illustrated out of each group.

Firstly, we would discuss cases in which apparatus has been fixed in the mouth before operation, and we have divided these cases into three classes: Class 1, where the loss of substructure is slight and only requires a modified splint denture. Class 2, cases in which large prostheses were required to replace extensive loss of bone in the superior maxilla. Class 3, cases in which large prostheses were required to replace extensive loss of bone in the mandible.

Secondly, two cases are here illustrated to represent the class in which failures have occurred owing to the absence of correct substructure.

Before going on to the illustration of our point by these chosen cases we wish to make a few general remarks on post-operative treatment, when the support is implanted in the mouth at the time of operation. These remarks will be confined to the maintenance of cleanliness and to the importance of keeping the prosthesis continuously in its position. We are very strongly of opinion that every effort should be made before operation to fix in the requisite appliance; that in any cases in which this is impossible owing to cicatricial bands, as much of the apparatus as possible should be prepared beforehand, and the rest fitted during the somewhat lengthy operation; that when fitted, and the fleshy covering has been brought into place, no attempt should be made to remove the prosthesis until the tenth day, by which time the flap should be firmly united. Cleanliness is maintained by the usual oral hygiene, and in lower-jaw cases, in order to avoid any cul-de-sac, external drainage is usually provided. We also practise very slight loosening of the apparatus in order that syringing may be more efficiently carried out. As before stated, however, no effort is made to remove the appliances from the mouth, and we have come to this conclusion for the following reasons. It is frequently impossible to remove a large prosthesis; the removal causes pain to the patient, the apparatus seldom

replaces itself into exactly the same bed, and it is never so comfortable after replacement. Moreover, the continual taking out and putting in of the mechanical support very considerably disturbs the commencing union of the flaps, allowing septic material from the mouth to invade the tissues. We are thus following the cardinal principle of keeping the parts at rest, and we think we have shown that the cleanliness of the mouth is not hereby jeopardised.

Of the cases in which successful prosthesis has been applied at the time of operation,

*Class 1.*—Cases in which modified splint dentures. The greatest care is taken by Captain King and his staff to see that the apparatus is made to fit as firmly as possible, and that no roughness will be exposed to the tissues. Artificial teeth are usually added, which give not only confidence to the patient, but also guidance to the surgeon. Two cases (Figs. 1-5 and Figs. 6 and 7) illustrate this class, but do not require any special description of dental apparatus.

*Class 2.*—Cases in which large prostheses are required to replace large loss of bone in the superior maxilla.

*Private G.* (Figs. 8-10).—This case is characterised by large loss of the superior maxilla, together with almost complete loss of the upper lip. There remained only a small tag of mucous membrane near the left angle of the mouth. The prosthesis was made to represent the lost bone, and the skin and mucous flaps formed over it. Result of first operation shown.

*Private A.* (Figs. 11-14).—This case showed not only extensive loss in the upper jaw but also fracture of the lower. The edentulous condition made the work of the dental surgeon particularly difficult, and the favourable result of the first operation, as shown in Fig. 12, was only made possible by the three months' dental work, which consisted of (1) a palate plate which replaced the tissues of the palate; (2) a splint retaining the three fractured parts of the mandible in correct position; and (3) a vulcanite flange to support the lips and cheeks during and after operation.

*Class 3.*—Lower-jaw cases with large loss of bone requiring large prostheses.

*Private G.* (Figs. 15-17).—This man was edentulous, and had suffered a large loss of bone as well as lip. A lower denture was fitted, replacing the lost parts, and the plastic operation performed over it. The figures illustrate the condition on arrival and after one operation.

*Private O.* (Figs. 18 and 19).—This case shows the result of a plastic operation rendered simple by the preliminary dental treatment, which consisted in the fitting of upper and lower vulcanite splints, and the support externally of the chin by a vulcanite splint supported to the head with elastic. The patient was edentulous.

The other side of our argument is well illustrated by the unfavourable results obtained in the following cases, where, for various reasons, some unavoidable, no suitable apparatus was continually kept in position after the operation.

*Sergeant E.* (Figs. 20-23).—Operation performed for the formation of the new upper lip. The prosthesis made was not retained in position, and the inferior result is shown in the figures, necessitating the division of buccal adhesions and the stretching of the lip. A subsequent plastic operation has been done.

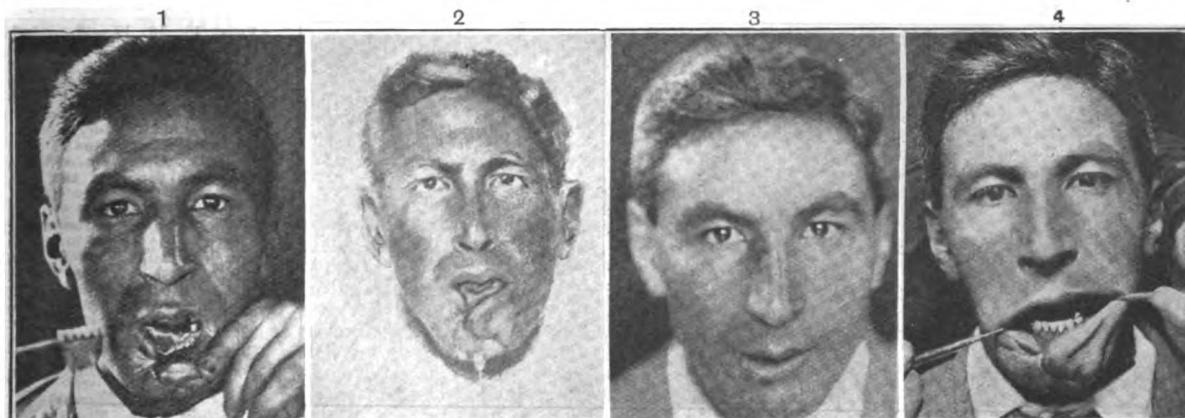

*Sergeant H.* (Figs. 24-27).—This case was characterised by very large loss of mandible, in the region of the angle, combined with buccal fistula. The dental treatment consisted in maintaining occlusion of the remaining teeth by a fixed biting flange enabling him to masticate. This flange (Figs. 25 and 27) was constructed by Captain F. E. Sprawson, R.A.M.C. An operation for the closing of the buccal fistula resulted in primary union, but owing to the very large loss of mandible, there is an unsightly depression which would not have occurred if it had been possible to insert any apparatus to take the place of the large bone loss. The loss of function in this case is so slight owing to the excellent articulation of the remaining teeth that a contemplated bone graft has been abandoned. Patient can eat his ordinary home diet.

*Continued from preceding page.*

a small opening between. I exposed the posterior wall in the usual manner through a rent in the transverse mesocolon. I did an anastomosis by suture between the upper and lower pouches. The patient made a complete and rapid recovery and was apparently free from all stomach trouble when leaving the hospital three weeks after operation.

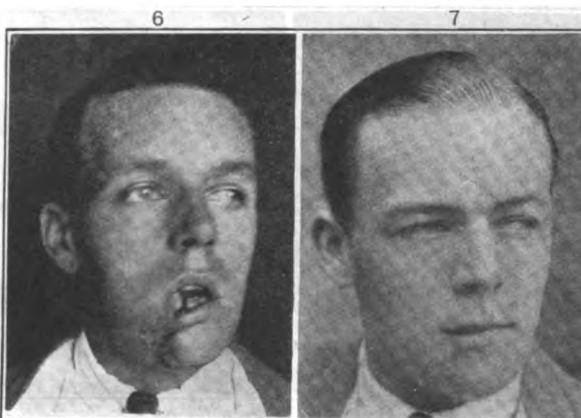

I owe an apology for bringing up for discussion a subject about which so much has been written, but I hope to have done something to direct attention to the early and accurate diagnosis of a condition which, when not detected promptly, is nearly invariably fatal.

Dublin.

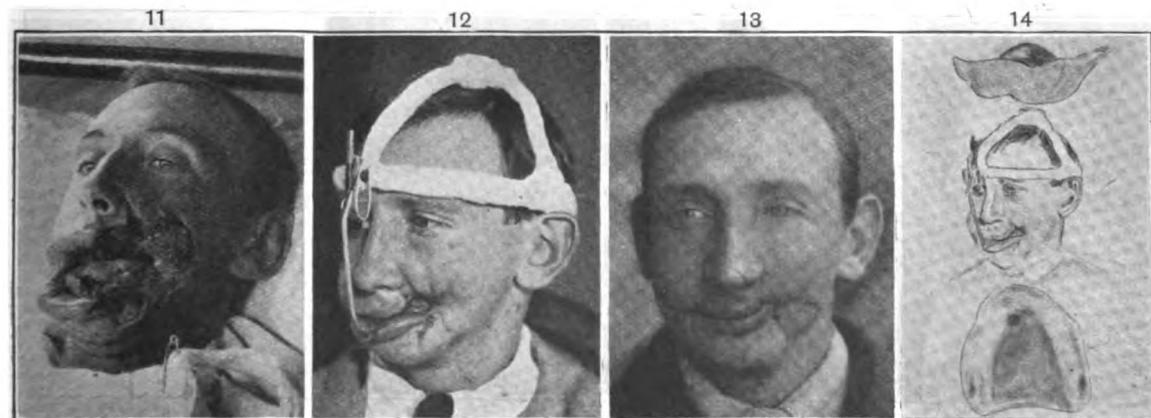

FIGS. 1 to 5.—Wounded 1/7/16. The deformity is well illustrated in Fig. 2, from a drawing by Prof. Tonks, F.R.C.S. Plastic operation 17/8/16. The radiating scars were all excised and by utilising the healthy skin in between scars it was not necessary to make any special flaps. The result is shown in Fig. 3.

FIGS. 6 and 7.—Wounded 1/7/16; operation, 16/8/16. Loss of bone through *whole* thickness of mandible. Operation: Performed over a modified splint denture, which retained the jaw in position. A successful osteoperiosteal bone graft from the tibia has since been performed.

FIGS. 8, 9, 10.—Wounded 14/8/16; operation, 5/10/16. The main principles in this operation were thick lateral-nasal flaps from the cheek combined with mucous membrane flaps from inside. The result of the first operation is shown. Further improvement in the mouth and nose have since been made.

FIGS. 11 to 14.—Wounded 1/7/16. Characterised by partial loss of superior and inferior maxilla, cheek, upper lip and corner of mouth. Result of the first operation on 4/10/16 is shown in Fig. 13; his condition immediately preceding is shown in Fig. 12. Fig. 13 result was obtained by cutting two flaps, one from the cheek and one from below the chin. Subsequent operation has markedly improved the left corner of the mouth.

## PLASTIC REPAIR IN WAR INJURIES TO THE JAW AND FACE.

BY PERCIVAL P. COLE, M.B. BIRM., F.R.C.S. ENG.,  
HONORARY SURGEON, KING GEORGE HOSPITAL, LONDON; OPERATING  
SURGEON, BROOK WAR HOSPITAL; ASSISTANT SURGEON, SEAMEN'S  
HOSPITAL, GREENWICH, ETC.

THE cases naturally group themselves into two classes, according to the nature of the deformity produced. In the one class the deformity is due to laceration with little or no loss of soft tissues; in the other, and more important, category definite destruction of soft parts gives rise to deformity which varies directly with the loss sustained. In both classes there may be an associated injury to or loss of bone, a complicating factor which has an important bearing on the mode of treatment to be adopted.

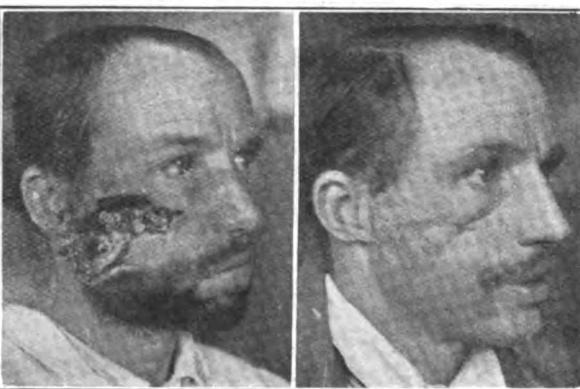

In all cases functional must take precedence of cosmetic considerations. Bony lesions must first be dealt with in such a way as to make possible the restoration of normal function. It may be laid down as an axiom that the repair of damaged or destroyed soft parts should never be undertaken until fractured fragments have been efficiently splinted. It may be thought unnecessary to lay stress upon such an apparently self-evident essential. Many cases, however, have come under my care in which such repair has been carried out, and that before a permanent splint had been adapted. In these cases it has been necessary to undo all that has been done to enable an efficient appliance to be inserted. Broadly speaking, early suture in cases associated with bony lesions is not to be recommended. In uncomplicated laceration, with little or no loss of tissue and not involving the mucous membrane of the cheek, early suture has a definite claim to consideration. Time will be saved and the formation of scar tissue to a large extent obviated. Where extensive laceration is associated with definite loss of tissue it is obvious that a depressed scar will result unless the lost tissue can be replaced. The best means of dealing with such a condition is the insertion of an autoplastic graft, a measure that will not be attended with success until every source of sepsis has been eliminated—that is, until

the wound is soundly healed. The illustrations show the condition of such a wound on admission (Fig. 1) and after operation (Fig. 2). The most ugly scars can thus be treated with the certainty that a satisfactory cosmetic result will be achieved.

It is, however, in the repair of lesions associated with loss of substance involving the mucous membrane either of the lips, cheek, or nose that the surgeon is afforded the greatest scope for the exercise of judgment and ingenuity. The one object always to be borne in mind is that any procedure must be so planned as to assure that the functional activity of the jaws shall be in no wise diminished. The paramount importance of this consideration and the greater ease and certainty of its attainment when the operation is undertaken at a later stage is the chief argument for adopting a waiting policy. Ingenious apparatus for the stretching of scar tissue has been devised, figured, and described by dental surgeons both in this country and abroad. The only objection to their use is that in a properly conducted case they are totally unnecessary; it is obviously a sounder policy to prevent cicatricial contraction, or to plan operations in such a way that due allowance is made for such contraction

as must take place, than complacently to allow crippling contractions to occur and endeavour to redeem the situation by laborious methods designed to stretch and expand them. It is in this policy of prevention that my colleague, Mr. C. H. Bubb, has rendered me such invaluable service. The preservation of the buccal sulcus should be the constant aim of surgeon and dental surgeon alike, and both can contribute to its attainment. The importance of this cannot be too strongly emphasised. Failure in this respect renders the adaptation of a denture or prosthetic appliance very difficult, and frequently impossible, with the result that the implicated side of the jaw is rendered totally functionless. The cosmetic result in such a case may be entirely satisfactory; a fair exterior may decorously mask a functional failure.

In some cases associated with extensive bony lesions the loss of soft parts is more apparent than real. The skin edges curl over and invert to a degree sufficient to permit firm adhesion to the margins of the bony gap. This applies particularly to injuries of the upper jaw and the overlying tissues. Much can be done in such a case by freely stripping the tissues from the bone, followed by careful and separate readjustment of mucous membrane and skin surface. Figs. 3 and 4 illustrate the appearance of a case of this type before operation. The patient had been wounded three months previously. A suitable splint was inserted and retained until the parts were soundly healed. Fig. 5 shows the appearance after the sixth operation; the splint is in position. The associated bony lesions were destruction

of the greater part of the left maxilla, including the corresponding portion of hard palate, together with entire loss of the left ascending ramus, which was removed as a sequestrum. On admission to my wards at the King George Hospital cicatricial contraction had taken place to such an extent that the patient was unable to open his mouth more than one-sixteenth of an inch. A prosthetic appliance has been constructed and inserted by Mr. Bubb to such good purpose that the patient's functional capacity has been completely restored. In Fig. 6 is shown the final result. The nose is artificial; it was made and modelled by Mr. Brooks.

In most severe cases the tissues have suffered such a degree of destruction that mere readjustment will not suffice to ensure a satisfactory result. Some form of flap must be utilised to make good the loss sustained. The various types of flap may be classified as follows:—

I. *Single flaps*.—1. Sliding. 2. Transposed, the type commonly used to remedy ectropion. These two forms can only be used when the tissues in the immediate neighbourhood of the gap are sufficiently lax to admit of direct borrowing. 3. Transferred, depending temporarily for blood supply on a pedicle situated at a distance. 4. Hinged. A flap rotated on a hinged pedicle formed at the margin of the gap.

II. *Doubly epithelialised flaps*.—1. Formed in the gap coincident with its closure by the interposition of a single flap with the immediate or later imposition thereon of a second single flap. 2. Formed at a distance, formation antedating closure, (a) with one primary pedicle, (b) with two primary pedicles.

The use of single flaps is practically confined to reparative work on the lips. For this purpose the sliding and transposed flaps only can be utilised. The mucous membrane on the deep surface is included in the flap.

Plastic repair of lower lip and chin is illustrated by Fig. 7 (before operation) and Fig. 8 (after operation). There was an associated fracture at the symphysis with considerable loss of bone. The operation was performed with a suitable splint *in situ*. Another example is illustrated in Figs. 9 and 10. The bony lesion in this patient was similar in nature. The functional capacity of both these patients has been completely restored.

The type of case suitable for the employment of a double flap formed in the gap and coincident with its closure is shown in Fig. 11. In Fig. 12 the flaps are shown in position immediately after operation. The under flap is pedicled and its raw out-turned surface is uncovered at its posterior part. The superimposed flap is of the sliding variety. Fig. 13 exhibits the pedicle cut, the spare skin being used to relieve tension in the neck. The associated bony lesion was a badly comminuted fracture of the lower jaw on the left side. Firm bony union had occurred before the operation was undertaken.

The combination of hinged and pedicled flap is shown in Fig. 14. In Fig. 15 the condition before operation may be seen, the skin margins being everywhere turned in and adherent to bone. The under flap is formed from the skin of the face and rotated, with its skin surface towards the nasal cavity, on a hinge formed at the lower part of the gap. This flap is entirely covered, as is the raw surface left by its formation, by the superimposed pedicled flap taken from the scalp. This flap was 7 inches long and its pedicle is shown before severance. The union has given way over a small area at the upper margin of the gap. In Fig. 16 the pedicle has been cut and the redundant portion of the flap replaced to make good the deficiency in the scalp.

Some gaps are more conveniently closed by means of double epithelialised flaps formed at a distance. Such a case is seen in Fig. 17. The tongue is protruding on the lateral aspect of the neck. The lower margin of the gap is dotted with displaced necrotic fragments of bone. Fig. 18 shows the condition attained before closure was attempted. Fixation of the bony fragments by a suitable splint has determined contraction of the tissues towards the fixed points, and new bone has spread along the whole length of the gap. The condition after closure of the defect and severance of the pedicle is illustrated in Fig. 19. The flap that was used in this case was fashioned with a single primary pedicle. The scar in the neck indicates the original site of the flap. Muscular control of the lips has been perfectly restored and complete restoration of mastication is assured.

Where, on account of the size of the defect, large flaps must necessarily be employed, it will be found advantageous

to utilise two primary pedicles. The type of case for which such a procedure is indicated is shown in Fig. 20. The soft tissues have been completely destroyed over the area illustrated, exposing an irregular bony bed made up for the most part of malar bone and posterior wall of the antrum. This patient, when transferred to my wards, had absolute trismus owing to cicatricial contraction. This was efficiently rectified and a splint inserted (Fig. 21). A double flap was fashioned having one pedicle at the upper part of the chest wall and another in the neck. These were stitched together, raw surface to raw surface. At a later date the chest pedicle was cut. Fig. 22 shows the flap swung into position, with the neck pedicle intact. The skin surface derived from the anterior chest wall forms the inner surface of the false cheek. In Fig. 23 the pedicle has been divided and the right angle of the mouth reconstituted. This patient was to have been sent away to be provided with a face mask. Other operations have been and remain to be performed before the case is finished. Even if, at the stage depicted, artifice had been invoked as a cosmetic aid, plastic surgery would have conferred upon this patient the inestimable advantage that his functional capacity, both as regards control of saliva and masticating power, had, by the use of his own tissues, been fully restored. It is certain that the resources of plastic surgery are adequate to deal effectively with numbers of cases for which various types of artificial apparatus are employed. Surgery alone can reconstitute; artifice must substitute. In some cases, undoubtedly, the best possible results will only be achieved by drawing on the resources of both.

The anaesthetics were most skilfully administered by Dr. Francis E. Shipway and Mr. Ramsey Phillips. Intratracheal ether has been the routine method adopted, not only for the type of case herein described, but also for such procedures as the taking of impressions, insertion of splints, and operative measures for the immediate reduction of deformity in old and recent fractures of the jaw.

The benefits that accrue from the use of this method cannot well be exaggerated. For the surgeon operating is rendered easy and comfortable in that all his energies, untrammelled by extraneous considerations, can be devoted to the immediate task in hand; the mouth is, as it were, a limb. For the patient nausea, vomiting, and post-anæsthetic complications are eliminated.

The marked tendency to keloid in some of the patients has led to the trial of methods for the alleviation of this disfiguring condition. Passive hyperæmia and ionisation have been employed without avail. The most successful results have been obtained by the use of X rays and radium. Dr. Robert Knox has very kindly carried out treatment by these agents in the electro-therapeutical department of the Cancer Hospital. His results clearly indicate that the most disfiguring scar can be effectively dealt with by these methods. The photographs were taken by Dr. A. Norman, to whom my best thanks are due for the time and labour devoted to their preparation. These have been, in most cases, taken very soon after operation. Considerable improvement in appearance invariably occurs after a few months and may be aided by growing a moustache or beard. In every case function has been completely restored or its restoration has been definitely assured. The care of these cases demands from the nursing staff the exercise of the greatest patience, and entails constant and scrupulous attention to detail. It is a great pleasure to acknowledge the whole-hearted enthusiasm with which they and my resident, Mr. T. H. Lunney, have devoted themselves to the work.

It may be stated, in conclusion, that the type of case herein discussed comprises one variety only of the cases admitted to my wards at the King George Hospital. They all have this in common, in that the plan of treatment for each individual is determined by conjoint consideration, conjoint aim, and conjoint action on the part of my dental colleague Mr. Bubb and myself.

Harley-street, W.

**THE LATE BENJAMIN POWER BEAMES BURROUGHS, M.R.C.S., L.S.A.**—Mr. Burroughs died on Feb. 16th, at his residence at Weston-super-Mare, in his seventy-first year. He was a son of the late Mr. R. C. Burroughs, barrister-at-law, and had practised in Weston for over 40 years, where he was much respected. He was for several years on the honorary staff of the Royal West of England Sanatorium.

**THE  
ANTIBODY CONTENT OF THE CEREBRO-  
SPINAL FLUID IN MENINGOCOCCAL  
INFECTIONS,**

WITH SPECIAL REFERENCE TO VACCINE TREATMENT.

BY FRANK E. TAYLOR, M.A., M.Sc. VICT.,

M.D. LOND., F.R.C.S. ENG., D.P.H. CAMB.,

LECTURER ON BACTERIOLOGY IN THE UNIVERSITY OF LONDON, KING'S COLLEGE; PATHOLOGIST AND BACTERIOLOGIST TO THE QUEEN ALEXANDRA MILITARY HOSPITAL, MILLBANK.

(A Report to the Medical Research Committee.)

THE vaccine treatment of many infective conditions, more especially of chronic infections, has now become a widely practised therapeutic procedure. It is a firmly established and well-known fact that a vaccine on injection into the tissues acts like all antigens do in stimulating the production of specific antibodies in the body tissues and fluids of the injected individual. Not only can the presence of these specific antibodies—whether bacteriolytic, agglutinating, complement-fixing, or opsonic—be readily recognised in the blood serum, but by the exercise of the appropriate technique their amounts can be determined with great accuracy. Certain of these methods, indeed, have now become the commonplace procedures of the clinical laboratory, being in daily use for the detection and differential diagnosis of many infective diseases.

There is also some evidence to show that these specific antibodies are not confined to the blood, but may also be found in the other body fluids, more particularly the lymph. An exhaustive investigation into their presence and abundance in various other body fluids, such as the cerebro-spinal fluid, the aqueous humour, the lacrymal fluid, ascitic, pleural, and pericardial fluids, and in various transudates and exudates, would probably throw much light on the exact seat of origin of these bodies.

The question of the presence or absence of these antibodies in the cerebro-spinal fluid becomes an important one in the consideration of the vaccine treatment—prophylactic or curative—of meningococcal cerebro-spinal meningitis, for unless the antibodies reach the interior of the thecal sac, and so be present in the cerebro-spinal fluid, the indications for the exhibition of the vaccine injected subcutaneously would be lacking.

Vaccines have already been administered in this condition, either alone or as an adjunct to other methods of treatment, but according to the official report of the Medical Research Committee on Cerebro-spinal Meningitis no very satisfactory clinical results have been recorded, and so no very definite indications or contra-indications for or against their use can be obtained on clinical grounds alone.

The opportunity of investigating this question experimentally was presented to me whilst working in the London District Cerebro-spinal Fever Laboratory at the Royal Army Medical College at Millbank last year in association with Captain Arthur Davies, R.A.M.C., who suggested this investigation to me, while Lieutenant-Colonel Mervyn Gordon, R.A.M.C., kindly supplied the materials employed.

Young rabbits of 1000 to 1500 grammes weight were inoculated with gradually increasing doses of meningococcus cultures until the blood serum showed a high grade of agglutination towards the strain of the organism injected, several different strains of the meningococcus being employed in the various experiments. The animals were then bled, the serum being employed by Lieutenant-Colonel Gordon<sup>1</sup> in the agglutination and absorption experiments, which proved that four chief strains or types of meningococcus were responsible for the cases of cerebro-spinal fever met with in this country.

The animals, along with a little of their sera and a culture of the infecting organisms, were then handed over to me. The cerebro-spinal fluid was obtained by puncture of the spinal theca through the occipito-atlantoid ligament, where spinal puncture is most easily performed in the rabbit. In some cases blood-stained fluid was obtained. This was at once rejected and only cerebro-spinal fluid free from any trace of blood was employed.

The agglutination titre of the blood and of the cerebro-spinal fluid was then ascertained, the macroscopic method of agglutination being employed. A suspension of a 24-hour culture of the injected coccus in normal saline solution heated to 65° C. for 30 minutes was employed, the heating being employed not only to kill the micro-organisms but also to inactivate the autolysin, for it has been shown by

Raymond Koch that such a heated suspension of meningococci keeps well and gives reliable results for many months. The results were read off after 24 to 48 hours as recommended by Kutscher. The results obtained are set forth in the following table:

*Table Showing Agglutination Titre of Serum and Absence of Agglutinins in Cerebro-spinal Fluid of Rabbits Injected with Various Types of Meningococcus.*

Expt.	Type of meningococcus injected.	Agglutination titre of serum.	Agglutination titre of cerebro-spinal fluid.
1.	Carter, Type I.	1 in 320.	Nil.
2.	Chase, Type III.	1 in 320.	..
3.	Shore, Type III.	1 in 256.	..
4.	McPhail, Type II.	1 in 256.	..
5.	Uninoculated control.	Nil.	..

The results obtained in these experiments show that although the serum of the injected animals exhibited a fairly high agglutination titre against the homologous types of meningococcus, the cerebro-spinal fluid in all cases showed no trace of agglutinating properties.

Hitherto very few investigations have been carried out on the antibody content of the cerebro-spinal fluid and these chiefly with *B. typhosus*.

Thus Rosenberg<sup>2</sup> studied the concentration of typhoid agglutinins in the body fluids of rabbits immunised against the typhoid bacillus. He found that the concentration of the agglutinins depends on their concentration in the blood, and that ascitic fluid and pleuritic and pericardial fluids contain a greater percentage of agglutinins than do cerebro-spinal fluid, aqueous humour, and urine.

Braude and Carlson<sup>3</sup> have shown that the serum, thoracic lymph, neck lymph, and pericardial fluid of normal dogs contain agglutinins for the typhoid bacillus, being most abundant in the serum, whilst the cerebro-spinal fluid and the aqueous humour possess no agglutinating properties. In dogs immunised against typhoid bacilli, however, they found that agglutinins were present even in considerable quantity both in the cerebro-spinal fluid and the aqueous humour.

Hughes and Carlson<sup>4</sup> investigated the haemolytic power of the body fluids of normal dogs and found that although the serum of the dog is haemolytic to rabbits' erythrocytes, no lysis of rabbits' corpuscles was produced by the cerebro-spinal fluid of any of the 15 dogs investigated.

Working with human body fluids Pick<sup>5</sup> and Levy and Geisler<sup>6</sup> have described the presence of bacterio-agglutinins in the cerebro-spinal fluid and aqueous humour, pericardial fluid, and various exudates and transudates in patients suffering from typhoid infections.

Kohler<sup>7</sup> also found agglutinins present in the cerebro-spinal fluid of one out of a total of ten typhoid patients, whereas the same observer records the presence of agglutinins in the blood of non-typhoid patients as well as healthy individuals to the extent of 15 per cent of the subjects investigated. It would thus appear that the agglutinins encountered by Kohler were not specific typhoid agglutinins.

The work of Cavazzini,<sup>8</sup> Capalbetti,<sup>9</sup> Petit and Girard,<sup>10</sup> Meek,<sup>11</sup> and Dixon and Halliburton<sup>12</sup> seems to show that the cerebro-spinal fluid is formed, in part if not entirely, by the secretory activity of the epithelial cells of the choroid plexus, which Mott<sup>13</sup> speaks of as the "choroid gland." Extracts of this body stimulate the secretion of the cerebro-spinal fluid, whereas the quantity of this fluid is not affected by lymphagogues, but is increased by pilocarpine and checked by atropine, and after the injection of pilocarpine the cells exhibit the typical changes met with in active glands after secretion.

Hence we may conclude from a consideration of these experiments that the weight of evidence goes to prove that bacterial antibodies do not pass over, at least in any quantity, into the cerebro-spinal fluid, and that therefore little benefit can be expected to result from the subcutaneous administration of vaccines in cerebro-spinal meningitis.

I beg to express my indebtedness to Captain Davies and to Lieutenant-Colonel Gordon for suggestions and assistance, and to the Medical Research Committee, under whose auspices this investigation was undertaken.

# THE LANCET.

LONDON: SATURDAY, MARCH 17, 1917.

## The Training of the Disabled Soldier.

THE statement of Mr. Barnes, the Minister of Pensions, which was published in THE LANCET last week, on the provision to be made by the Government for men disabled in the war was not made too soon; it was much expected, and will be welcomed by all interested in the care of the war cripple. The War Office, said Mr. Barnes, has undertaken to retain the disabled man as an in-patient so long as there is accommodation for him, and during this time to provide him with manual curative treatment, or, in other words, trade workshops. In order that the Pensions Ministry may get in touch with the disabled man during his period in hospital, Mr. Barnes has adopted the scheme of the Disabled Soldiers Aid Committee, the voluntary body which for some time past has sent representatives to the various London military hospitals to interview the men before their discharge with a view to helping them to find training in skilled trades and subsequent remunerative employment. This visiting will now, therefore, become a general routine throughout the country and be done by members of the local War Pensions &c. Statutory Committees. After discharge from hospital the War Office has accepted responsibility for the man's further treatment as an out-patient in his own district; failure to accept such treatment will subject the man to the risk of losing half his pension, while the discharged man who trains for a new or more skilled occupation will have the inducement of receiving, in addition to his full pension and allowances, free tuition and a small bonus.

This marks a great advance, but it cannot be said that the scheme, as at present outlined, affords a complete solution of the existing difficulties. One of these, which has been experienced by the military authorities in all combatant countries, is to induce the convalescent men to attend the curative workshops where these exist. In the Hammersmith Military Orthopaedic Hospital this difficulty has been solved to a considerable extent by the granting or withholding of the special privileges which appeal to the soldier's mind, such as the wearing of khaki in place of hospital blue and the award of extra leave. Unfortunately, the limbless man does not respond in the same way to these attractions and some other suasion must be applied—a matter for the military authorities rather than the Pensions Ministry to devise. A more concrete difficulty is in regard to the provision of training facilities. It is, of course, possible to provide training in a trade at an existing local technical school or polytechnic, and at the same time

medical treatment at another local institution; but it is evident that much effort will be required to coördinate the two, and the cripple will inevitably lose more time each day than if treatment and training were provided under the same roof. At present, too, there is little indication that the local technical institutions are in a position to provide adequate facilities for training except perhaps in the largest centres of population, where, and where only, the different groups of disabled men are sufficiently represented to form classes in the various subjects.

In the direction of continued in-patient treatment, with all its attendant advantages, a promise of better things may be read into Mr. Barnes's announcement of the formation of a committee directly responsible to the Ministry of Pensions and charged with the task of providing institutional treatment for disabled soldiers after their discharge. The first of these residential institutions which is now approaching completion will deal with a hundred neurasthenics, with whom are to be associated half the number of men who have lost a limb or the use of a limb, the admixture of patients who have only or mainly physical ills to contend with being designed to relieve the mental atmosphere. We may reasonably expect that adequate workshop accommodation is being provided, and that this institution will be the forerunner of others scattered over the country. As the element of treatment is still the most important one in these residential institutions, we cannot help expressing some surprise that Mr. Barnes, in enumerating the personnel of his advisory committee, did not mention the existence of a medical member upon it. There must surely be some officer of a Command Depot with the necessary experience and administrative ability to qualify for this position. When the advisory committee has done its work we need no longer fear comparison with the French *écoles professionnelles* and the agricultural schools in that country for disabled men. At present, although generous financial provision has been made, the provision of technical re-education of the wounded in this country is below the level of that provided by continental nations, enemy and allied.

## Plastic Surgery of the Face.

THE war has afforded sad but great opportunities for the display of surgical skill in the refashioning of the face, and two articles in the present issue of THE LANCET—one by Mr. PERCIVAL COLE and the other by Captain H. D. GILLIES and Captain L. A. B. KING—will serve to show how much may be done by well-directed knowledge and skill in the obliteration of the ravages produced by weapons of war. It was natural that the face should be the region where plastic surgery should first gain successes, for inevitably it would be in this region that the earliest attempts would be made. The classic labours of TAGLIACOZZI were mainly directed to the replacing of noses and lips which had been removed either by injury or by disease. The results of operative interference were here, on the whole, disappointing. In India

at an early date attempts were made to replace lost noses, for in some parts of that country there is much scope for this operation, as slicing off the nose is the recognised method by which an irritated husband signifies his disapprobation of his wife's conduct. Colonel D. F. KEEGAN, I.M.S., has written in our columns and elsewhere very fully on the rhinoplasty designed to repair the husband's brutalities, and it is interesting to see that the treatment of some of our military patients to-day follows some of the methods of technique which he described.

In those wounds of the face inflicted upon patients who have returned to this country from the front for treatment the injury may be confined to the soft parts, in which case the art of the surgeon suffices in most cases to restore the appearance to a very great extent. In the slighter cases it may be sufficient to suture the edges of wounds, when there has been but little loss of tissue; but when the destruction of skin and other tissue has been great, then it becomes necessary to interpose skin from elsewhere to fill the gap, and these flaps may be taken from the neck or even from the chest in the frequent classes of injury where the lower part of the face has been mutilated. The flaps may be transferred by sliding, or transposed by the aid of a pedicle. When the mucous membrane of the mouth is intact, a simple flap of skin is quite sufficient to give good cosmetic results, but when, as occurs in so many cases, more or less of the mucous membrane has been lost it will be essential that a double flap should be employed, one flap being placed with its epithelial surface directed towards the mouth, so as to take the place of the lost mucous membrane, while the other flap is so applied that its epithelial surface is directed outwards. In some cases the raw surfaces of the two flaps are placed together at the same operation, while in others it may be advisable to insert the deeper flap at one operation, while the more superficial piece of skin is not applied until a later date. In both the articles published this week examples of the procedure in question are figured. The great need for the insertion of a flap of skin to replace lost mucous membrane depends on the fact that it is not sufficient to have a good cosmetic result, but it is essential that the functional result shall be perfect, for the operation has been useless if the jaws are held together immovable by a dense mass of cicatricial tissue, such as would follow healing after a great loss of the substance of the cheek were no new tissue interposed. Function in all cases is of more importance than appearance, though nearly always, if due attention be paid to function, the cosmetic result can be made satisfactory by ingenuity, patience, and the intelligent co-operation of the surgical with the dental expert. Sometimes one plastic operation will suffice; but as a rule more than one operation is needed, and not rarely many are required to obtain the best results. When in addition to the damage to the soft parts the upper or the lower jaw has been injured, the task of the surgeon becomes more

difficult still, and in all but the slightest cases he must, in order to attain success, have recourse to the assistance of the dentist. Should there be nothing more than a simple fracture of the jaw it may suffice to keep in position the parts of the broken bone, but nearly always there has been real loss of substance, and it is moreover rare for the fractures not to be compound, and comminution is almost the rule. In circumstances like these some mechanical support is necessary, and this must be provided by the dental expert. Such a support should be applied early, before any elaborate operation is undertaken to close the rent in the lips or cheek; for if it be postponed until some time after the operation is done, already no small degree of contraction will have taken place and the result will not be satisfactory. This point is emphasised by both Captain GILLIES and Mr. COLE. The planning and the fixing of the mechanical support are of the greatest importance and need meticulous care; but the results are commensurate with the care taken, and they are often almost miraculous. A glance at the illustrations accompanying the two papers we have mentioned will show clearly the marvellous improvement which can follow operations for bullet and shell wounds of the face and jaws. There seems to be no well-defined limit to what may be done given the requisite time, and cases which to the uninitiated must appear to be absolutely hopeless, may, after the fitting of dentures or other prosthetic appliances and after one or many operations, show but few and inconspicuous signs of the harm wrought by the projectile. There is one point in the plastic treatment of these extensive injuries to which sufficient attention is not always given, and that is the preservation of the buccal sulcus: for if care be not taken to see that the buccal sulcus is preserved, it becomes exceedingly difficult, if not impossible, to fit a denture to that side of the mouth, and functionally so far the operation has failed, for that side of the mouth cannot be used.

To sum up: In any but the slightest cases and those where there is only injury to the soft parts, it is above all things essential that the surgeon should invoke the aid of the dental expert. The prosthetic appliance needed should be fixed before the healing of the wounds has formed a cicatricial mass which will need stretching if any really useful result is to be attained, for it is far better to prevent cicatricial contraction than to have to stretch the scar tissue after it has formed. With skill and care and time results can be obtained which can hardly be credited by those who have had no opportunity of seeing them.

CENTENARIANS.—Mr. Thomas Pyper, for many years head gardener at Minterne House (Lord Digby's Dorset residence), has recently celebrated the 100th anniversary of his birthday.—Mrs. Anna Rogers, of Falmouth, celebrated the 100th anniversary of her birthday on Feb. 28th.—Mrs. Elizabeth Selley, who was born near Launceston, Cornwall, died at Gloucester on Feb. 2nd in her 102nd year.—Mr. John Hamlin, the oldest resident in Somerset, died at Shepton Mallet on Feb. 5th in his 102nd year.—Mr. James Newth died at the Grammar School House, Dursley, on Feb. 13th in his 103rd year.

## Annotations.

"No quid nimis."

### THE INFLUENCE OF DRESSINGS ON THE ANAEROBIC FLORA OF WOUNDS.

THE Tetanus Committee of the War Office are desirous of obtaining evidence of the persistence of anaerobic bacteria in wounds, and of the effect of various methods of wound dressing on the persistence of these anaerobes. They consider that if a sufficient number of pathologists would make routine observations for a short time upon two or three wounds each, much valuable evidence would be forthcoming, especially if the examinations were carried out in a similar fashion. The Committee therefore suggest a routine method suitable for the examination of one case, which could be extended to other cases during the same period if time permitted. The essential points to be noted for each case are : (I.) The type of dressing in use for the wound examined—e.g., (a) hypochlorite solution, (b) hypertonic salt solution, (c) salt pack, (d) peroxide, iodine and normal saline, (e) coal-tar derivatives (cresol, &c.), (f) flavine, brilliant green, &c. (II.) The presence or absence of spore-forming organisms as determined by : (a) direct films of wound discharge; (b) anaerobic meat broth cultivations. The following points are to be specially noted. 1. The presence or absence of spore-forming organisms and type of sporulation—e.g., (a) end spore, round or oval; (b) subterminal end spores (of which a small portion of stained organism can be seen beyond the spore); (c) central spores, including clostridial spore; (d) motility; (e) reaction to Gram's stain, noting morphology of organisms—viz., slender, thick rods, cocci, &c. 2. Changes in the meat medium: (a) reddening, (b) blackening, (c) gas formation, (d) digestion. A form of report is being issued to be returned when filled up to Surgeon-General Sir David Bruce, Royal Army Medical College, Grosvenor-road, London, S.W.

### THE DIETETIC VALUE OF ROOTS AND TUBERS.

THE prospect of a serious shortage in the potato supply is pressing into service other vegetables of the sort that may be substitutes. The general drawback to them all is the very large percentage of water which they contain compared with the potato. The potato itself contains on an average 75 per cent. of water, which, however, is much the same proportion as is contained in raw meat, while the turnip contains as much as 90 per cent. of water, which is 2 or 3 per cent. more than is contained in a fluid such as milk. The apparent solidity of the turnip is, in fact, remarkable having regard to its large percentage of water. Unlike the potato, however, the turnip or swede contains no starch, the predominant constituent of the potato, the carbohydrates present being in the form of sugar, and in the process of boiling much of this sugar is lost. The same is true of the beet-root, which, of course, is very rich in sugar. The carrot also contains a relatively large amount of sugar, while its percentage of moisture is less than that of the turnip but 10 per cent. more than that of the potato. The parsnip contains even more sugar than the beet, but rather less water. The protein value of all these vegetables is poor; they are valuable chiefly as sources of carbohydrate

in the form of sugar. They are bulkier foods than the potato owing to their large holding of water. The onion, containing as much as 90 per cent. of water, shows a small dietetic value, and its mission would appear to be rather that of a condiment than of a nutrient, and a very wholesome and serviceable condiment it is. There is one constituent of root foods which is sometimes overlooked, and which may have a definite dietetic importance, and that is the curious carbohydrate known as pectose, which appears to replace starch in certain vegetables, and notably the turnip. Pectose adds to the mucilaginous character of the puree, and it is the foundation of the gelatinising property of cooked fruit juices. The pectins, in fact, form gels, to use the modern language of colloidal chemistry. It is possible that this property of the pectins renders them a valuable adjuvant in the metabolic process apart from the consideration of a direct carbohydrate value. The word food commonly conveys a substantial material, but we cannot deny the importance of certain constituents in comestibles which, though they may not directly nourish, yet afford valuable, if not essential, assistance in the process of nutrition.

### THE LOUSE PROBLEM.

A DISCOURSE was delivered recently on the louse problem before the Section of Epidemiology and State Medicine of the Royal Society of Medicine by Mr. A. W. Bacot, entomologist to the Lister Institute, when the lecturer dealt with a subject of great importance in a thoroughly practical style. After setting out the points in the natural history of lice which concern all questions of prevention or cure of the evils due to lice—for example, their methods of pairing, their proceedings when egg-laying, their fecundity and fertility, their length of life, and their general habits—Mr. Bacot came to the following conclusions :

Eggs take 7 or 10 days to hatch under normal conditions—i.e., in clothing that is constantly worn; if discarded and allowed to cool for a period each day the time of hatching may be extended for five weeks.

Active lice can exist without food, and apart from any host, for periods of up to 9 days.

Young lice take from 10 to 14 days to attain sexual maturity.

Females, after attaining maturity, require 2 to 4 days before they commence to oviposit.

Egg production cannot take place without food, or under cool conditions (below 65° F.).

Eggs laid by unpaired females do not hatch.

Impregnation is not effective for more than 20 days.

As many as 10 or 12 eggs per day may be laid by each female.

A total of 300 eggs may be laid by one female.

The female after maturity may live for 46 days.

Before the close of her life a single female may have 4160 living offspring.

With regard to prevention Mr. Bacot pointed out that lousiness is a sign of a low standard of civilised life, and that the circumstances of war, by rendering the washing and changing of garments and bedding an erratic or occasional proceeding, produces such a standard on all the war fronts. The louse problem is solved, he suggests, in proportion as the armies are able to conduct campaigning under a civilised standard of life, which may be possible where the battle-front is more or less fixed and contiguous to resourceful bases, as in the West, but quite impossible where it is in motion, or relying upon long lines of difficult transport. Mr. Bacot, who has a neat turn of expression, pointed out that "it is one of the peculiarities of the destruction of insects that economy of thought

and extravagance in practice should be so general," and he finds that to the troops actually in the trenches the authorities have not had the prudence to issue a sufficient supply of insecticides, and have not recognised that, while all the known insecticides are defective in one direction or another, their imperfections may be counterbalanced by complementary use. Many of these preparations, employed by themselves, represent vain extravagance, but reinforced by others they constitute a valuable part of treatment. Slow acting and relatively stable remedies should be used together with those of quick action though short duration. In his opinion the treatment of discarded clothing should, wherever possible, be by dry heat, and, still with an eye to waste, he tells the story of an experimenter who found that "cylin water when cool was not effective, but became so when heated to 60° centigrade"—it had already been pointed out in his own paper that dry heat at 60° centigrade killed the nits.

Mr. Bacot's experiments upon insecticides were carried out upon his own person by the suspension between shirt and skin of gauze bags containing active lice; while in order to gauge the comparative value of a number of different remedies under practical conditions, and to determine their range of action, he constructed an apparatus to suspend in front of the body so that insects could feed during the progress of the tests. He came to the conclusion that however valuable and interesting from the view of pure science many of the published papers concerning the relative efficiency of various substances may be, they have but small practical value, owing to a want of appreciation of the essential facts connected with their use—namely, that remedies have to be applied between the clothing and surface of a more or less rotund body, the temperature condition there being in the neighbourhood of 87° to 92° F. What effect their vapour may have in closed tins, under bell jars, or when the lice are suspended within a short distance above the insecticides is beside the question; all depends, he shows, upon the concentration and duration of the vapour caused by the quantity applied to any given area, and the effective diffusion range around this area.

#### A DOUBLE RADIAL ARTERY.

AN instance of this very rare condition has recently been observed by Professor Edward Fawcett in the dissecting-room of the medical school attached to the University of Bristol. It was also associated with high bifurcation of the brachial artery, a condition which may usually with certainty be ascribed to persistence in some form or other of a *vas aberrans*. This high bifurcation is, in Professor Fawcett's experience, frequently associated also with an increased number of heads of origin of the biceps muscle. In this case three heads of origin were present.

The *vas aberrans* left the brachial artery at the lower border of the tendon of the teres major muscle, ran downwards superficial to the median nerve, and at about the middle of the upper arm crossed the superficial surface of the biceps to reach its outer side at the bend of the elbow. Below this point it bifurcated into two branches of equal calibre, one, more medial, which ran the course usually associated with the radial artery, the other, more lateral, which running by the side of the radial vein, superficial and lateral to the brachio-radialis muscle at the junction of the middle and lower thirds of the forearm was joined company by the radial nerve, and with it reached the back of the wrist. The branch first described turned backwards under the tendons of the extensor ossis metacarpi pollicis

and extensor brevis pollicis, having previously given off the anterior radial carpal and superficial volar branches; later it terminated under the extensor tendons at the back of the wrist as the posterior carpal artery, previous to which having given off the dorsal arteries of the thumb. The branch secondly described, having reached the wrist superficially, at once made for the proximal end of the first interosseous space, through which it passed to form the deep palmar arch, previous to which it gave off the dorsal artery of the index finger. From their behaviour and their equality in size one is justified in regarding each of these branches as a radial artery, hence the superscription—double radial artery.

The condition is naturally one of some interest to clinicians. Professor Fawcett states that he has not once met with it in a period of 30 years' dissecting-room experience, although he has been asked if such condition might exist by more than one clinician.

#### THE TENNENT CHAIR OF OPHTHALMOLOGY.

Dr. Gavin Paterson Tennent, who died in 1913, left £25,000 to the University of Glasgow for the establishment of a department of ophthalmology and for the foundation of a chair of Ophthalmology in the University. The salary of the new professor has been fixed at £500 a year, and his duties are "to apply himself to the promotion of higher study in ophthalmology and to the advancement of knowledge by means of scientific observation and research in relation thereto." The election to the chair is vested in a board of seven curators, four to be nominated by the University Court and three by the directors of the Western Infirmary. Glasgow and ophthalmology alike are to be congratulated on this munificent endowment. Glasgow is admirably adapted for the purpose, since it possesses a large and flourishing medical school and has a wealth of clinical material. There is therefore every probability that the Tennent Fund will be put to the most advantageous use, for it is of the greatest importance that the more purely scientific aspects of advanced medical studies should be kept in intimate touch with practical clinical work. We noted recently that a University Court ordinance has been presented for the foundation in Edinburgh of a chair of Tuberculosis, showing that this opinion is shared by the Scottish leaders of thought.

#### FACTITIOUS ELEPHANTIASIS.

AT a recent meeting of the Académie de Médecine of Paris Professor Meriel, of Toulouse, called attention to what appears to be a new factitious condition, induced for the purpose of avoiding military service. Among the wounded who came before a military board of which he was a member he saw a number of cases of elephantiasis of the limbs, predominating at the extremity, which followed a slight injury of warfare, such as wounding by a small fragment of shell or a burn of the second degree. The enormous oedematous infiltration, much out of proportion to the gravity of the injury, excited surprise. When a series of such cases came before him he began to investigate them. He found that the oedema was induced by constriction of the limb for several days with a bandage. In some cases a layer of cotton-wool was first interposed so as to prevent any marks of the bandage. Even when no trace of constriction could be found the appearance was characteristic; the oedema was sharply demarcated near the root of the limb by an elevated margin. This is never present in oedema due to

disease. The proposal to apply a plaster apparatus or its application often led to avowal of the cause. If it did not, the rapid disappearance of the œdema under the apparatus betrayed its origin. When the œdema was recent it was entirely curable, but when it had been maintained for a long time trophic lesions which did not disappear, or took a long time in doing so, were the result. The œdema affected the hand or foot and extended up the forearm or leg. It was of variable consistence, sometimes hard, but more often pitting on pressure. The skin of the affected part was glossy, thinned, cold, sometimes bluish, and at other times white. Whatever the upper limit the œdema terminated by a well-marked ridge above which the tissues were quite sound. Movements of the fingers were much diminished, and the fingers themselves were enlarged and separated from one another by the enormous lymphatic infiltration. The latter produced in the long run trophic lesions. Their existence was shown by radiography, which revealed decalcification of the bones of the hand and foot which was exactly the same as in a recent work on nerve lesions Madame A. Benisty has figured in a case of wound of the median nerve. In both cases the decalcification predominated in the phalanges and the head of the metacarpal bones. It is important to note that the œdema is not due to the neuritis, but the neuritis to the œdema. The neuritis does not recede as quickly as the œdema, but outlasts it for a greater or lesser period producing a disability desired by the subject. The diagnosis can be made by isolating and watching the patient so as to prevent him from constricting the limb or by enveloping the latter in plaster-of-Paris, which in the case of the lower limb should reach up to the pelvis and in the upper limb to the chest.

#### THE CHEMISTRY OF WAR-TIME WHISKY.

THE dilution of spirits with water, and particularly of malt whisky, down to the degree demanded by the Defence of the Realm Act has effected some important changes in the characteristics of this alcoholic liquor which are worth notice. It may be remembered that present supplies to the public cannot be sold at a greater alcoholic strength than 30° under proof spirit, which means about 33 per cent. of alcohol by weight or 40 per cent. by volume (70 per cent. proof spirit), whereas before any demand for dilution came into force the average strength of the spirit sold was about 40 per cent. by weight of alcohol or 48 per cent. by volume (84 per cent. proof spirit). This means that 20 gallons of water may be added to 100 gallons of the old-strength whisky to produce 120 gallons of a spirit diluted in accordance with the requirements of the Act. The dilution amounts, in fact, to the addition of about a fifth part water, so that a dozen bottles of the old-strength spirit would make about 14 bottles of the diluted spirit. If whisky were pure alcohol this dilution would give no trouble, but, as everyone knows, genuine malt whisky is not pure alcohol; it is a complex containing certain by-products of fermentation and distillation held in solution in the alcohol. Just as with tinctures the addition of water throws out oils and other active substances, so it happens with malt spirit. Fatty substances, resins, and other products contrive to make the spirit opalescent when water is added to

the extent demanded and when allowed to stand. The subsequent elimination of these substances by filtration carries out a material portion of the flavouring substances derived from the malt, and the ethers are to some extent destroyed by this process. This is what the merchants have been compelled to do; it was easy enough to water down the malt spirit to the required standard, but the mixture became opalescent and had to be carefully filtered before it could be bottled in a satisfactory condition. The result is that the whisky now supplied to the public is bright and clear and remains so even on further dilution, while much of the characteristic malty flavour has been withdrawn. This change in the character of whisky may have its hygienic advantages, inasmuch as it may not satisfy the taste of the habitual consumer, and may induce him to drink it less frequently or not at all.

#### THE FREE SUPPLY OF ANTITOXIN IN CANADA.

THE Provincial Board of Health for Ontario has now completed a contract for a year for the supply of diphtheria antitoxin, tetanus antitoxin, anti-meningitis serum, small-pox vaccine, and Pasteur preventive treatment for rabies. We announced early last year the intention of the Board to make a gratuitous distribution of these serums, and our readers will like to know the details of such an example of public forethought. These serums, as well as mixed typhoid and paratyphoid vaccines, have been supplied free to the public all over the province of Ontario. Diphtheria antitoxin costs the Board 15 cents per 1000 units, in vials, tetanus antitoxin 30 cents per 1000 units, in vials, anti-meningitis serum \$1 per 20 c.c., small-pox vaccine 4 cents per capillary tube, and Pasteur treatment \$15 per person treated. Mixed typhoid and paratyphoid vaccine is prepared and supplied free by the Board's laboratory, in Toronto. The aggregate cost of supplying the province for the year is about \$40,000, or about one-quarter of the cost under commercial prices. All these products, except typhoid vaccine, have been, and will be for the future, obtained from the University of Toronto, and are prepared at the Connaught antitoxin laboratories about 12 miles outside of the city. Since the war began the Board has supplied all the typhoid and paratyphoid vaccine used by the Canadian troops (some 400,000 doses) free of charge. The enterprise of the Board has been the subject of well-deserved appreciation from the public and the medical profession.

Colonel J. T. Fotheringham, C.M.G., who came over in medical charge of the 2nd Canadian Division, has been invited to deliver the next Cavendish Lecture of the West London Medico-Chirurgical Society about the middle of June. The subject of the lecture will be the modern organisation of the medical service at the front.

**LITERARY INTELLIGENCE.**—The first number has just appeared of a new journal of general physiology, *Archives Néerlandaises de Physiologie de l'Homme et des Animaux*, edited by W. Einthoven, H. J. Hamburger, C. A. Pekelharing, G. Van Rijnberk, et H. Zwaardemaker, and forming part of a series of scientific archives published by La Société Hollandaise des Sciences à Harlem. Four numbers make up the volume, for which the subscription is 15 florins payable to Martinus Nijhoff, Lange Voorhout 9, The Hague, Holland.

## THE CONTROL OF VENEREAL DISEASES.

### *The Preventive Treatment of Venereal Diseases in Australia.*

Temporary Lieutenant-Colonel James W. Barrett, R.A.M.C., has sent us the following letter for publication:

In consequence of the appearance of a leading article in your issue of Jan. 13th on the subject of venereal prophylaxis, I venture to place your readers in possession of the facts relating to the steps which have already been taken in Australia. In the State of Victoria the Government has done much in the direction of investigating the extent of distribution and in educating the public respecting the nature of venereal diseases. The Governmental action was the result of a medical campaign of 20 years' duration, details of which are set out in the Proceedings of the various sessions of the Australian Medical Congress and in an article written by myself and published in Bedrock early in 1913. It was the action of the Victorian Government which, to some extent, influenced the appointment of the British Royal Commission. In 1914, however, it was found that the Government was hesitating respecting publication of the methods relating to prophylaxis, and consequently a small committee of medical men and women (of which I was a member) was formed and determined to take action on their own responsibility. They accordingly drafted the appended circular and arranged with the leading chemists in Melbourne to supply the articles necessary for the prophylaxis of venereal diseases, and to issue the leaflet with the articles purchased.

Before doing so, however, information relating to the step proposed to be taken was sent to every medical practitioner in the State of Victoria and to every member of the clergy, with a request for an expression of opinion whether a better method could be devised. A conference with the representatives of the Council of Churches made it clear that, whilst the clergy disliked the proposal, they were unable to suggest any alternative method; action was accordingly taken. In the course of the discussion the medical representatives made it abundantly clear that the principles which must underlie the suppression of venereal diseases are: 1. The complete separation of the moral from the medical problem, and the clear recognition of the fact that the world will not be rendered more or less moral by the abolition of venereal disease. 2. The fact that the fear of the acquisition of venereal disease is no effective deterrent to immorality; to such slight extent as it is a deterrent the advantages are more than counterbalanced by the wholesale infection of the innocent which goes on at present. 3. That as the organisms which cause venereal diseases grow almost exclusively in the genital passages of men and women, it is quite clear that the intelligent use of prophylaxis would in a very few years eliminate these diseases altogether; in fact, it is doubtful whether there are any other contagious diseases which could be eliminated with greater certainty.

It is to me an article of faith, fully discussed in the literature referred to, in the *Australasian Medical Journal*, in the columns of the *Melbourne Argus*, and elsewhere, that a resolute and straightforward attack on this problem on the lines of prophylaxis offers the only reasonable means of extirpating these diseases. The other and indirect means of dealing with it have a value, and education respecting the nature of the diseases is especially useful, and it is the lack of knowledge on the part of the public which has caused the failure of past campaigns. Yet these means alone are somewhat disappointing in their results as our experience indicates. The words used by Huxley in another connexion may be applied with great force to this colossal evil: "There is no alleviation for the suffering of mankind except veracity of thought and action, and the resolute facing of the world as it is, when the garment of make-believe by which pious hands have hidden its uglier features, is stripped off."

May I commend the foregoing to the consideration of earnest men and women who are now publicly facing this disagreeable but vital undertaking.

The Australian circular runs as follows:—

#### WARNING: VENEREAL DISEASES.

Irregular sexual intercourse involves a considerable liability to infection with gonorrhœa, or syphilis, or both. Of those who are infected a portion are never cured; the consequences are serious so far as they are concerned, and still more serious as regards those to whom they may communicate these diseases later on. A single exposure to infection may result in life-long illness.

Incontinence is not in any way necessary for purposes of health, and the advice the medical profession would give to all would be abstinence from intercourse other than in marriage. If you desire in the future healthy children and a healthy wife, you are strongly advised to remain continent; at the same time, if you determine to take the risk, it is your duty, not only for your own sake, but for that of other people, to avoid infection, and infection can be avoided or lessened in frequency by following the procedure indicated in the following.

*Instructions for men.*—Immediately after intercourse thoroughly wash the genitals with soap and water, pass urine, and then dry the parts, especially the opening of the passage. The washing must include the parts under the foreskin, which must be drawn back. Then dip the wisp of cotton-wool into the liquid supplied and gently pass it into the opening by a twisting movement; pass it in for a quarter of an inch, and allow it to remain in position for three or four minutes before removal. If the opening or "eye" of the penis is so small that this cannot be done a few drops should be inserted with a medicine-dropper. The ointment is then to be used by rubbing it in thoroughly and firmly over the whole penis, but more particularly the head, especially if a crack, abrasion, or small tear is noticed anywhere. The foreskin must be drawn back to allow of this being done properly. A small portion of the ointment should be allowed to remain in opening of the canal. The value of these simple precautions depends on the rapidity with which they are adopted after intercourse. The sooner these steps are taken the less is the risk of infection. The applications should be made in the order indicated. The longer they are deferred the greater the risk.

*Instructions for women.*—If there has been any risk of infection as soon as possible after connexion douche well, using a quart of hot water and putting into it two teaspoonsful of tinct. of iodine. Then smear the calomel ointment round the outside of orifice and well up over the front.

The ointment: 30 per cent. calomel; the solution: 20 per cent. argyrol. (This may be made into a jelly with glyco-gelatine.) These articles are now sold by leading chemists.

#### *Resolution of the Royal Society of Medicine.*

At a recent meeting of the Council of the Royal Society of Medicine the following resolution was unanimously passed:—

That, in view of the grave national dangers arising from the neglect, or the improper treatment, of venereal diseases, the Council of the Royal Society of Medicine is strongly in favour of legislation for the purpose of rendering it a penal offence for any person other than a registered medical practitioner to treat or advise concerning the treatment of these diseases, or to sell, supply, or dispense drugs as a remedy for venereal diseases, unless the said drugs are supplied on the prescription of a registered medical practitioner, and only for the exclusive use of the person for whom the said prescription was intended.

#### *The Y.M.C.A. and Venereal Diseases.*

The recent report of the Microscopical Section of the Y.M.C.A. to the National Council of Associations states that there is much evidence among the men in camp that venereal diseases are spread through ignorance and thoughtlessness. At the exhibitions one member of the party makes it his duty to exhibit bacteria, and amongst them the germ of syphilis, with a view of opening a discussion among the men on the subject. The younger soldiers and sailors invariably put questions indicating a belief that brothels can be visited with impunity. Statements of fact illustrated by the microscope are then made by the exhibitor to show that such beliefs are unfounded and likely to lead to disaster.

#### *Outfit for the Treatment Centre.*

With commendable enterprise the Holborn Surgical Instrument Company (26, Thavies Inn, London, E.C.) have issued a 16-page catalogue of apparatus and remedies suitable for a venereal treatment centre. The cover describes the "606 Apparatus, Military Outfit," as used at the Military Hospital in Rochester-row; two pages follow on syringes and needles; then the drugs, new and old, in various forms; general apparatus, urethral instruments, a special "606 table" with hinged arm rests; ending with a complete estimate of the outfit required under three heads: (1) the 606 and mercurial injection room; (2) the gonorrhœa treatment room; (3) apparatus for the Wassermann test and dark-ground work. The list will be of use to centres not already fully equipped.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *The Aphony of War and Laryngeal Tuberculosis.*

AMONG the accidents attributable to the war one of the most unexpected and difficult to interpret is aphony. It is not a rare accident. Dr. G. Liébault, chief of an oto-rhino-laryngological centre, has made a special study of these cases. Some of them may be attributed to a nervous traumatism caused by the bursting of the shells, but the majority of patients state that their aphony has followed on the fatigues and chills of trench life. The diagnosis of simple nervous aphony has frequently been established, but many also are under suspicion of a commencing laryngitis. When transferred from service to service these men are incompletely treated and do not improve. They are as a rule exhausted; they have often been several months in the trenches; they are thin, physically depressed, and in need of rest; they have a cough and a hoarse voice. It is natural for the doctor who sees them to conclude that the bronchitis

and laryngitis, along with fatigue and emaciation, are evidence of a tuberculous affection. It is, however, imperative that the larynx should be completely examined, and it may then be found that the patient is by no means tuberculous. M. Liébault has successfully treated ten soldiers who had been under care at several hospitals and were well on their way to being discharged. Without exhaustive examination these cases should not be labelled as bacillary and discharged.

#### *Extraction of Projectiles.*

M. René le Fort has several times essayed with success the extraction of projectiles from the root of the lung. He considers the best means of access is the anterior flap, comprising the second, third, fourth, and even the fifth ribs, and turned outwards. The lung may readily be displaced, and both surfaces of the hilum reached from before and behind. The after-treatment of the operation, which may itself be critical, is generally simple, although the interference is more serious than in the case of projectiles in the body of the lung. To reach projectiles situated on one or other side of the vertebral column in front of the transverse processes M. Salva Mercadé holds that the sub-peritoneal route presents undoubted advantages. The peritoneum is easily separated, and when turned back with the contained viscera an extensive view is obtained of the posterior abdominal wall. M. Mercadé employed this method on a man sent to him with a radiographic note stating that the projectile was situated 7 cm. deep from the anterior abdominal wall measured from a point two finger-breadths below and to the right of the umbilicus, and 8 cm. from the posterior surface of the body. The projectile was found in the psoas at the level of the fourth lumbar vertebra, and the patient made a good recovery.

#### *Artificial Limbs and Muscular Re-education.*

Professor Amar, analysing, by means of his dynamographic footpath, the locomotion of amputation cases, has thus passed under review various types of prosthesis—artificial legs, articulated and rigid, orthopaedic boots, and the like—supplied for amputations of thigh, or leg, or for crippled feet. He finds that the curves of effort registered show that at present no model, either French or foreign, has realised conditions of walking approaching the normal. The characteristics of the pathological gait are still to be noted; inertia, lack of stability, compass movement of the legs in progressing, and rapid fatigue. From Professor Amar's tracings it results that, in spite of half a century of experience, the artificial lower limb is still highly irrational and little in harmony with the physiological laws of locomotion and of the conservation of energy. Dr. Charmot has made a study of the professional re-education of one-armed agricultural labourers. According to the latest figures agricultural labourers make up nearly two-thirds of the war cripples' and of amputation cases the upper limb accounts for about two-thirds. Thanks to modern artificial aid, it can be safely affirmed that all labourers retaining as much as one-third of the crippled arm can and should remain in agricultural pursuits after suitable re-education. To control the results obtained competitions have been organised by the Society of Technical Instruction of the Rhône and the Association of Assistance of the Mutilated at Lyons. At the first of these meetings 12 men presented themselves. They were required to dig and to reap. In digging, those who had lost an arm got through their work in a shorter time than those who had lost a forearm, and even than normal men. The second fact is explained by the intensity of work due to competition, and the first by the fact that the movements of an arm stump are simpler and more limited than those of a forearm stump. In reaping, those who had lost an arm or a forearm reaped 4 ares in about an hour, while a normal individual, doing average work, only reaps in the same time 3½ ares. Of course, in a competition the work is of short duration and intensive. But tests of longer duration were also tried. Thus four one-armed patients reaped between them in three days 1½ hectares working from five and a half hours to six hours a day. These men rapidly reach the stage of doing whole days' work without fatigue. Their mental outlook is a matter of importance. They are easily distressed, often embittered. This must be borne in mind and their training based on physiological data, taking care never to reach the limit of fatigue, and to surround the crippled with an atmosphere of sympathetic encouragement.

## THE SERVICES.

### ROYAL ARMY MEDICAL CORPS.

Temp. Capt. F. J. Ewing, C.A.M.C., to be Deputy Assistant Director of Medical Services.

Lieut.-Col. G. A. Moore, C.M.G., to be temporary Colonel whilst employed as Assistant Director of Medical Services of a Division.

The undermentioned to retain the acting rank of Lieutenant-Colonel: Capt. T. S. Eves, whilst commanding a Field Ambulance; Major D. O. Hyde, D.S.O., whilst commanding a Casualty Clearing Station; Major B. B. Burke, D.S.O., whilst commanding a Stationary Hospital.

To be acting Lieutenant-Colonels whilst commanding a Field Ambulance: Capt. T. H. Scott, M.C., and Temp. Capt. F. F. Muecke, L. D. Shaw, R. H. Drake-Brockman.

Major William Riach, C.M.G., to be acting Lieutenant-Colonel whilst commanding a Casualty Clearing Station.

To be temporary Majors: C. Christie and Temp. Major W. H. Laughlin, C.A.M.C.

Capt. B. Biggar is seconded for service with the Egyptian Army.

To be temporary Captains: A. G. Leitch, T. S. G. Martin, R. S. Miller, A. R. J. Douglas, H. Hebblewhite (Major T.F.R.), T. J. Burton, F. A. Murray, H. J. Cooper, and temporary Lieutenants E. Baldwin, T. Davidson, J. H. Patterson, J. S. Dickson, W. T. Patterson, G. Collins, J. R. Briscoe, P. W. Brigstocke, H. W. Barber, H. E. Williams, P. R. Eakell, H. M. Wilson, H. R. Davies, H. N. Rankin, L. F. West, C. H. G. Philip, W. O. Roberts, H. P. Caithness, H. Gardner-Hill, W. H. Hart, H. A. Boyle, S. B. Bethell, C. A. L. Evans, A. C. MacKay, W. Corbet, J. H. Waterhouse, B. R. Dermer, J. B. Robertson, G. M. Vevers, G. O. Hampson, J. B. Stevenson, W. J. Dilling, K. T. Limbrey, L. R. Pickett, A. McCawley, D. J. Evans, J. A. Tippett, P. H. Young, E. B. Barnes, J. B. Rae, J. M. Ross, C. I. Hannigan, O. W. Gange, J. G. Leslie, C. D. Coyle, L. G. Reynolds, G. L. Pillans, W. L. Paterson, D. J. Bedford, A. F. Wilson-Gunn, W. H. Pearce, A. Trall, M. Moran, A. R. Mitchell, W. O. Welby, J. M. Stalker, D. Crellin, P. Black, L. F. Hirst, R. C. Hewitt, J. C. O'Farrell, E. G. Dingley, P. H. Wells, A. L. McMaster, W. M. Christie, W. G. G. Coulter, D. G. MacArthur.

To be temporary Lieutenants: H. E. Batten, H. Whalley, J. L. D. Lewis, G. T. Watson, D. Lynch, W. M. Oakden, W. J. Oliver, J. M. Dickson, C. G. Lees, J. G. Reidy, C. L. Levers, H. B. Emerson, R. M. Liddell, H. H. Moyle, J. C. Jones, F. B. Mathews, C. J. Marshall, R. S. Drew, D. F. Brown, W. Venis, H. N. Wright, R. J. Lytle, J. F. Allen, V. J. Bonavia, I. C. Edwards, C. P. Crouch, W. Grier, C. B. Richardson, V. M. Walsh, J. S. Byrne, W. T. Harris, J. F. Blackett, E. M. Brown, H. H. Bywater, H. Harrison, G. H. U. Corbett, P. M. Tolmie, F. Humphreys, C. A. R. Nitch, J. W. Shields, A. H. H. Barclay, P. W. L. Andrew, J. P. Grainger, J. N. Beatties, L. C. Rorke, S. H. Davison, J. P. Ryan, J. Holland, J. Good, A. G. Harvey, E. B. Owens, C. H. Bannerman, P. Quinn, N. B. Stuart, J. T. Titterton, A. B. Moffatt, P. L. Hope, A. R. H. Geyer, D. R. Acheson, R. Stewart, W. L. Nicholson, W. Butterley, M. P. O'Brien, J. Martin, R. C. Hutchinson, F. R. Smyth, P. Al'an.

W. B. Hayes, temporary honorary Lieutenant whilst employed with No. 8 British Red Cross (Baltic and Corn Exchange) Hospital.

Officers relinquishing their commissions: Temp. Hon. Capt. R. S. Bernard (Fleet Surgeon, B.N., retired), Temp. Capt. F. W. Bird, R. D. Rankin (Can. A.M.C.), W. S. Heron, H. W. Doll, W. T. James, S. B. Faulkner, E. L. Mansel, P. W. White, J. P. Fitzpatrick, H. A. Gillespie, J. T. Smeall, S. G. Tippett, H. W. Ward, M. M. Townsend.

To be temporary Lieutenants: J. B. Carmichael, G. Hart, C. E. Cameron, L. Page, E. M. Ashcroft, H. E. Allanson, N. A. Boswell, W. Hughes, J. E. Bromley, H. N. Ingram, J. H. Mullan, J. K. Garner, T. T. O'Callaghan, D. M. Hunt, J. Pennmann, E. C. E. Barnes, A. C. D. Newton, J. McHaffie, N. Garrard.

Temp. Hon. Capt. H. W. Carson, having ceased to be employed with No. 10 British Red Cross (Lady Murray's) Hospital, relinquishes his commission.

### SPECIAL RESERVE OF OFFICERS.

Capt. R. T. C. Robertson to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Lieut. (on probation) T. Parr is confirmed in his rank.

To be Lieutenants: E. A. C. Langton, F. E. Leblanc, A. A. Pitch (from University of London Contingent, O.T.C.), R. Woodsdale, G. M. Herriott, A. A. Pritchard, and J. W. Gordon and J. A. Tolmie (from Edinburgh University Contingent, O.T.C.).

### TERRITORIAL FORCE.

To be acting Lieutenant-Colonels whilst commanding a Field Ambulance: Capt. H. K. Dawson, Major P. R. Ash, G. W. Miller, H. E. Corbin.

To be acting Lieutenant-Colonel while commanding a Casualty Clearing Station: Major R. Stirling.

Major (temp. Lieut.-Col.) T. Holt relinquishes his temporary rank on alteration in posting.

Capt. (acting Lieut.-Col.) F. Coleman relinquishes his acting rank on ceasing to command a Field Ambulance.

Capt. (temp. Major) A. Don relinquishes his temporary rank on alteration in posting.

Capt. (acting Lieut.-Col.) S. F. Linton relinquishes his acting rank on ceasing to command a Field Ambulance.

Capt. (temp. Major) A. Elliot to be Major.

Lieutenants to be Captains: J. Anderson, R. W. Nevin, L. A. Celestin, D. F. Torrens.

W. B. Evans, from Royal Highlanders (T.F.), to be Lieutenant.

Major B. H. Myddleton-Gaye relinquishes his commission on account of ill-health, and is granted permission to retain his rank and wear the prescribed uniform.

Lieut. C. E. Proctor resigns his commission.

Major R. J. R. C. Simons, Ret. List, R.A.M.C. (T.F.), is granted the honorary rank of Lieutenant-Colonel.

### VOLUNTEER FORCE.

Temp. Second Lieut. G. Cowen, Surrey Volunteer Regiment, 5th Battalion, and O. R. M. Wood, Suffolk Volunteer Regiment, 2nd Battalion, to be temporary Lieutenants and Medical Officers.

J. H. Rowe (late Lieutenant, R.A.M.C.), Yorkshire West Riding Volunteer Regiment, 21st Battalion, to be temporary Lieutenant.

## JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

Wounds of the knee-joint, though apparently trivial, may give rise to serious complications and present many anxious problems to the surgeon. From this point of view Temporary Colonel Andrew Fullerton, C.M.G., consulting surgeon to the British Expeditionary Force, contributes a useful and well-illustrated article on the surgical anatomy of the synovial membrane of the knee-joint to the February issue of the *Journal of the Royal Army Medical Corps*. Temporary Lieutenant H. D. Adrian continues his investigations on the electrical reaction of muscles before and after nerve injury. There is a further instalment of the inquiry by Lieutenant-Colonel C. M. Wenyon and Captain F. W. O'Connor into problems affecting the spread and incidence of intestinal protozoal infections of British troops and natives in Egypt, with special reference to the carrier question, and the treatment of amoebic dysentery; an account is given of three new human intestinal protozoa. In this connexion it may be mentioned that Lieutenant-Colonel Wenyon contributed to our columns in 1916 (vol. ii.), a valuable article on the common intestinal protozoa of man, while further notes on the subject, with illustrations, appear from his pen in the same volume. Among other papers of interest is one by Major Alfred J. Hull on the treatment of gunshot wounds by packing with salt sacs, and another by Major A. F. Hurst on Trench Fever: a Relapsing Fever among the British Troops in France and Salonica. Each of these papers was sent to both the *Journal of the Royal Army Medical Corps* and to THE LANCET for publication, the first appearing in our issue of May 27th, 1916, p. 1077, and the second on Oct. 14th, 1916, p. 671, though in the present instance Major Hull's paper is reinforced by notes of cases, clinical charts, and other illustrations. Many readers will welcome the reappearance of the contributions from Colonel R. H. Pirth under the title "Some Musings of an Idle Man."

## URBAN VITAL STATISTICS.

(Week ended March 10th, 1917.)

**English and Welsh Towns.**—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18,000,000 persons, the annual rate of mortality was equal to 17·1, against rates declining from 22·5 to 18·4 per 1000 in the three preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 18·5, or 0·5 per 1000 above that recorded in the previous week; among the remaining towns the rates ranged from 7·7 in Edmonton, 8·8 in Dewsbury, and 9·5 in Walthamstow, to 25·6 in Dudley, 27·4 in Warrington, and 29·0 in Hastings. The principal epidemic diseases caused 340 deaths, which corresponded to an annual rate of 1·0 per 1000, and included 179 from measles, 55 from infantile diarrhoea, 48 from diphtheria, 44 from whooping-cough, 9 from scarlet fever, and 5 from enteric fever. The deaths from measles showed a further increase in the numbers in the six preceding weeks, and caused the highest annual rates of 1·8 in Bolton and in Oldham, 2·7 in Acton, 3·0 in Wigan, and 4·1 in Dudley. The 811 cases of scarlet fever and the 1472 cases of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 18 below and 6 in excess of the numbers at the end of the previous week. Of the 5692 deaths from all causes in the 96 towns, 168 resulted from violence. The causes of 51 of the total deaths were uncertified, of which 9 were registered in Liverpool and 6 each in Birmingham and Manchester, but only 2 in London.

**Scotch Towns.**—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death rate was equal to 16·7, against 19·6 and 17·9 per 1000 in the two preceding weeks. The 352 deaths in Glasgow corresponded to an annual rate of 16·4, against 18·5 per 1000 in London, and included 16 from whooping-cough, 7 from measles, 2 each from diphtheria and infantile diarrhoea, and 1 from scarlet fever. The 104 deaths in Edinburgh were equal to a rate of 16·3 per 1000, and included 5 from whooping-cough, 4 from measles, and 1 from diphtheria.

**Irish Towns.**—The 186 deaths registered in Dublin were equal to an annual rate of 24·3, or 1·2 per 1000 less than that recorded in the previous week, and included 17 from measles, 4 from infantile diarrhoea, 3 from whooping-cough, and 1 from enteric fever. The 184 deaths in Belfast corresponded to a rate of 24·4 per 1000, and included 7 from measles, 3 from enteric fever, 2 from infantile diarrhoea, and 1 from diphtheria.

**CORNWALL INSURANCE COMMITTEE AND UNREGISTERED DENTISTS.**—At the last meeting of the Cornwall Insurance Committee it was reported that the Sanatorium Committee had recommended that no action be taken in the matter of a letter sent by the secretary of the Panel Committee. This communication referred to the action of the committee in requiring medical men, under exceptional circumstances, to meet unregistered dentists, and pointed out that such action was entirely contrary to the rules of the General Medical Council. It was mentioned that the reason why the Sanatorium Committee had advised no action was because they had no intention of using the services of any unregistered dentists.

**THE LATE THOMAS KNOX, L.R.C.P. & S. Irel.**—The death occurred on March 2nd, at his residence, of Mr. Thomas Knox, who for the past 35 years has been medical officer of Lisnasken Dispensary District and Workhouse and Fever Hospital, county Fermanagh. He was also medical officer of health of Lisnasken Union and medical attendant of the Royal Irish Constabulary. Mr. Knox was educated at the medical school in Dublin attached to the Royal College of Surgeons in Ireland, and became a Licentiate of that body and of the Royal College of Physicians of Ireland in 1874. He was 66 years of age and was a deservedly successful and popular practitioner.

## Correspondence.

"Audi alteram partem."

## EARLIER POST-OPERATIVE RAYING OF BREAST CANCER.

*To the Editor of THE LANCET.*

SIR,—I am very glad to see the letter from Mr. J. J. Grace advocating the earlier post-operative raying of breast cancer. I have been keenly interested in this matter for many years, and as far back as the spring of 1911, in a paper read before the West London Medico-Chirurgical Society, I strongly advocated the administration of a massive dose of the X rays to the site of operation before the closure of the wound, as this seemed the only logical development along the lines then practised. No serious objection has been raised to this suggestion, and to a radiologist at least it is difficult to understand why surgeons have been so reluctant to adopt this more generally. Even yet there are a few who do not have their breast cases X rayed after operation and even advise against it. As Mr. Grace points out, the surgical technique of these operations has been so elaborated that it approaches perfection, yet local recurrence takes place with undesirable frequency. No amount of skill and care will enable any surgeon to be quite sure that he has removed every trace of malignancy from an operation area, but he will greatly increase the patient's chance of a permanent cure by calling in the aid of the radiologist promptly, and what is equally important, leaving him to do his part of the work in his own way. The radiologist knows and understands the tools he is working with, and may be trusted to do no more and no less than his experience has taught him.

Probably no class of work presents greater difficulties in obtaining reliable data. Many cases come too late to derive any permanent benefit, others, after being much benefited, cease attending for various reasons, and are difficult to trace; but an experience lasting as long as the subject itself, and running into many hundreds of cases, leaves me thoroughly convinced that in the X rays we have a power over malignant disease that is capable of exerting a profound influence on our results. This power is much greater than it was even a few years ago and is still increasing; so much is this the case that we now obtain results scarcely hoped for a few years ago. This was well demonstrated in a series of cases shown by Mr. O. L. Addison and myself at the January meeting of the West London Medico-Chirurgical Society, and I think it may be said that those present received a lesson on the usefulness of the X rays in malignant disease that was somewhat of a revelation. The details of one of the cases shown may be given.

The patient was a man of 42 with a large mass in the abdomen about the size of a coconut. At the operation Mr. Addison found this to be a lympho-sarcoma with deposits in the stomach and liver and closed the incision without attempting removal. As soon as the patient was able to be about he came for X ray treatment, placing himself unreservedly in my hands. The mass rapidly diminished in size, digestion and health improved concurrently, he put on weight, and at the time of the meeting, seven months after the operation, he had been back to his work for some weeks and feeling quite well. Nothing could be then felt in the abdomen. He still comes for treatment, though not so frequently as before, and remains well at the present time. It is not suggested that this case is cured, but the result is a striking one nevertheless.

The other cases were scarcely less remarkable and all showed in the most unmistakable manner that in the modern developments of X ray technique we have a weapon of high value in our war against the scourge of malignant disease.

Regarding the closer co-operation between the surgeon and the radiologist in dealing with this problem I entirely endorse the plea contained in Mr. Grace's letter; as my writings will prove, I have been advocating this ever since 1903, and while there have been many discouragements I still hope to live to see the day it becomes the established practice. The partnership is one that holds nothing but good for all concerned, and no surgeon who has his patient's, and incidentally his own, interests at heart can afford to neglect this important aid to a permanently successful result, and

personally see that it is carried out. In the absence of facilities for raying at the time of operation the treatment should be commenced within a day or two—as soon as the patient has recovered from the anaesthetic and shock of operation. It is not necessary to disturb the dressings or the patient, as efficient treatment can be given at the bedside with a portable apparatus. Time is a most important factor for success, and we cannot afford to lose a single day's unnecessary delay. In the succeeding months further series of applications are given at gradually increasing intervals, with a diminishing number of applications in each series, and where this is carried out consistently it is rare to meet with local recurrence. More often secondary deposits arise in the spine or elsewhere, which is evidence of the case coming too late for operation or too late in being referred for radiation—perhaps both.

There is hardly any stage of malignant disease in which the X rays cannot be of some value. Inoperable cases are relieved of pain, and some of them through shrinkage, and becoming more movable, actually become operable, so that the case takes on a new aspect. Also the influence of modern X ray methods on a stinking, fungating, cancerous ulcer is such as would scarcely be believed by anyone who had not seen it for himself. I have caused such a mass to dry up completely, so that the last months were made reasonably comfortable and free from this most revolting feature.—I am, Sir, yours faithfully,

REGINALD MORTON,

Medical Officer in Charge, X Ray Department, West London Hospital.

Harley-street, W., March 12th, 1917.

## THE FIRST SCHOOL FOR MOTHERS.

To the Editor of THE LANCET.

SIR,—In reference to Dr. E. Pritchard's letter in your issue of March 3rd it may be said at once that my claim should have been limited to the question of precedence between Winchester and St. Pancras. To any school founded before November, 1906, I offer my humble apologies, provided it has been conducted from the beginning on the lines of the French institutions to describe which the name "School for Mothers" was originally coined.

In Dr. W. J. Maloney's translation of Budin's "Nursling," published in 1907, the following references to *Consultations de Nourrissons* will be found. Professor Budin (p. 148) recalls how one of his pupils had "aptly" said "these consultations are really schools for mothers." In the same lecture he exhorts medical men, whether their lot be placed in town or village, to organise consultations for nurslings. Dr. H. de Rothschild called Professor Budin's consultation a school for mothers (p. xxii.). In his preface (p. vii.) Dr. Maloney has written:—

Every practitioner, ..... whether his sphere be large or small, can find a consultation for nurslings. There is nothing costly or complex in Professor Budin's methods. All that is necessary is an apparatus for sterilising milk, a balance, and the energy of a medical man.

Winchester, in November, 1906, provided the balance and the energy of a medical man to hold the consultations and raise the number of admissions to 102 and the attendances to 790 in the year 1908. The centre was therefore a consultation for nurslings and as such entitled to the description "School for Mothers," unless it can be shown that Dr. Maloney has misrepresented his teacher's views and methods, or that English methods and terminology were not in the first instance borrowed from France. There was no apparatus for sterilising milk, and if Winchester on that account is to be ruled out it will disappear in good company with St. Pancras. If not, then for the sake of historical accuracy Dr. Pritchard may safely amend his statement, "St. Pancras was not even the second," to read "St. Pancras was not even the third," since Winchester and Marylebone were both in the field at an earlier date.

Among the earlier centres of which I have first-hand knowledge the Finsbury Milk Depôt, provided by the Social Workers' Association, under the guidance and direction of Dr. (now Sir) George Newman, should be mentioned. The balance required by Dr. Maloney, sterilised or pasteurised milk controlled from its source at the farm, and infant consultations held by medical men, were provided at the depôt. It was not mentioned in my first letter because infants

fed on the breast alone did not attend. I now find that the same somewhat serious defect existed at many of the French centres which Professor Budin has nevertheless referred to as consultations. Keeping, therefore, to the historical derivation of the title, the Finsbury Depôt should undoubtedly be ranked as a School for Mothers with priority from the date of its establishment on Nov. 23rd, 1904. In the "pioneer" (a loose term loosely defined in Webster's Dictionary) and "propaganda" work which has never been claimed for Winchester, Finsbury is well known to have played a part of the first importance.—I am, Sir, yours faithfully,

J. E. SANDILANDS.

Campden Hill-gardens, W., March 6th, 1917.

## THE CLOSURE OF COLOTOMY OPENINGS.

To the Editor of THE LANCET.

SIR,—There is a simpler method of closing colotomy openings than either of those described by Mr. F. Lockhart-Mummery in your issue of March 10th.

The patient having been anaesthetised, a piece of sterilised oiled silk 10 inches square is laid over the gauze dressings covering the opening, and its inner vertical edge sutured to the skin of the abdomen, so as effectually to shut off the opening from the field of operation. The abdomen is then opened to the mesial side of the oiled silk by a vertical incision passing through the left rectus sheath. On inserting broad retractors, the posterior aspect of the anterior abdominal wall is well seen, together with the involved portion of the colon adherent to it. The proximal and distal limbs of this are divided between clamps, end-to-end anastomosis performed as described by Mr. Lockhart-Mummery in his second method, and the bowel dropped back into the abdomen. The involved portion of the colon thus cut off from the rest of the bowel is disposed of by the method of invagination. A stout silk ligature is placed around each stump and the clamps removed. For the first time during the operation the dressings are removed from the colotomy opening, and an assistant introduces through it the opened blades of a pile forceps and passes them into the proximal limb, guided by the surgeon; the latter invaginates the stump upon itself, pushing the ligatured end between the blades, which the assistant closes firmly. The assistant next introduces a second pair of forceps into the distal limb, and in like manner, aided by the surgeon, seizes its ligatured stump. He then withdraws the two pairs of forceps simultaneously from the colotomy opening, which has the effect of completely invaginating the involved portion of bowel and carrying it outside the abdomen. Viewed from inside by the surgeon, all there is to be seen is a dimple in the parietal peritoneum. The surgeon closes the abdominal wound without a drain, applies a dressing, flaps over the oiled silk, and while the assistant makes traction on the forceps, ligatures the base of the invaginated mass, which is then cut off. A separate dressing is applied and the oiled silk returned to its original position. The wound of operation heals by first intention, and the opening in the skin and abdominal wall where the colotomy was, by granulation.

The great advantages of this method are the rapidity with which it can be performed and the shutting out of the colotomy opening from the field of operation until the latter has been all but completed.

I am, Sir, yours faithfully,

PAUL BERNARD ROTH,

Late Specialist in Operative Surgery, Aldershot Command.

Harley-street, W., March 12th, 1917.

## THE DIET OF THE BRAIN-WORKER.

To the Editor of THE LANCET.

SIR,—In support of the suggestion made in the annotation under the above heading in your issue of this date, that a brain-worker should take a diet of energy value equivalent to that of moderate muscular work, it may be of interest to record the following evidence on the subject. The late Field-Marshal Sir Lintorn Simmons, than whom a more painstaking and accurate observer never held rank in the British army, informed me some years ago that while he was governor of Woolwich Academy he kept notes of the amount of animal food consumed by the cadets, and found, to his surprise, that while they were under examination they consumed considerably more butcher's meat than at any other time in the academic year. The fact is the more remarkable in that during that period they were precluded in the main from taking outdoor exercise and from indulging in games and

field sports. When discussing the subject later Sir James Paget told me that his observations and personal experience fully confirmed Sir Lintern Simmons's statement, adding that when on a holiday, spent largely in the air, he felt little or no need for animal food, but ate it with keen appetite when full work in London debarred him from outdoor exercise. All the information which I have been able to glean in my own sphere of work strengthens the conviction that mental concentration creates such an appetite for animal food as points to a physiological demand.

I am, Sir, yours faithfully,

Harley-street, W., March 10th, 1917. W. BEZLY THORNE.

### THE AGE LIMITS OF PREGNANCY.

To the Editor of THE LANCET.

SIR.—I wish to establish, if possible, as a fact whether there is or is not a case of "a woman aged 48 or over having a living or viable child," recorded on evidence other than the *mere ipsa dixit* of the woman as to her age. Might I enlist the assistance of your readers to enable me to settle the point by reporting to me any cases within their knowledge. I am, of course, aware that there are a good many reported on the evidence of the mere statement of the woman that she was 48 or older; but as the Registration of Births Act is now over 50 years old it should be possible to get the date of parturition and the date of the mother's birth both officially recorded, and it is cases of this nature I am anxious to obtain for a forthcoming edition of "Taylor's Medical Jurisprudence."

I am, Sir, yours faithfully,

138, Harley-street, W., March 1st, 1917. FRED. J. SMITH.

### THE INTRAVENOUS INJECTION OF QUININE.

To the Editor of THE LANCET.

SIR.—With reference to the annotation on the above subject in your issue of March 3rd we should like to draw the attention of your readers to the advantages of colloidal quinine. Exhibited as a 1 per cent. "solution" the latter is on the alkaline side of neutrality and the temporary upset of injecting an acid solution either intravenously or intramuscularly is avoided. Furthermore—and this has been supported by laboratory experiment on animal veins—absorption of the quinine by osmosis and other mechanical factors into the tissues is much slower than in the case of molecular quinine solutions. We think it probable that the quinine in any case when injected must reach the colloidal state, and the statement of Dr. G. Arellano and his colleagues which you publish is of interest with regard to this when they say:

"It has been observed at times, especially when time is lost in inserting the needle, that a kind of flocculent precipitate is formed similar to that of "aluvine" when injected intravenously; but, as in that case, experience has shown it to be perfectly safe, it being a sort of emulso-suspensoid."

The precipitate at first formed undoubtedly goes into colloidal solution, but in doing so there is always upset of complement (*in vitro*, complement is destroyed).

In the use of quinine internally as an antiseptic, recommended by Dr. Vincent J. Glover in the same issue, the delayed absorption and elimination and the consequent prolonged antiseptic action of colloidal quinine administered directly as such opens a field of considerable possibilities.

I am, Sir, yours faithfully,

J. F. WARD

(For Crookes' Colloids, Limited).

Elgin-crescent, W., March 6th, 1917.

**STANDARDISED TUBERCULINS.**—We have received from Messrs. Duncan, Flockhart, and Co., of Edinburgh, samples of tuberculin prepared by the Research Laboratory of the Royal College of Physicians of Edinburgh, under the personal direction of Professor J. Ritchie. These include old tuberculin (T.), human and bovine, new tuberculin (T.R.), and bacillary emulsion (B.E.), put up in sterilised glass capsules containing a definite quantity of the original material or of desiccated bacilli. For the convenience of hospitals and other public institutions undiluted tuberculins are also issued. The Research Committee may be congratulated on its enterprise.

## The War.

### THE CASUALTY LIST.

The following names of medical officers appear among the casualties announced since our last issue:—

#### Died.

Major S. D. Rowland, R.A.M.C., was educated at Berkhamsted and at Downing College, Cambridge, and was a student at St. Bartholomew's Hospital, London, qualifying in 1897. Joining the staff of the Lister Institute shortly afterwards, he later went to India to undertake work in connexion with the Plague Commission. On the outbreak of war he joined the R.A.M.C., and went to France in charge of No. 1 Mobile Laboratory. He died in France on March 6th.

Lieut.-Col. S. W. Hewetson, Canadian A.M.C., was a student at McGill University, and qualified in 1893.

Major H. Jones, Canadian Army Medical Corps.

#### Wounded.

Lieut. D. P. Thomas, R.A.M.C., attached Royal Field Artillery.

Capt. R. P. N. B. Bennett, M.C., R.A.M.C.

Lieut. D. N. Fraser, R.A.M.C.

Lieut. A. Y. Dabgoekar, I.M.S.

Capt. G. W. Rogers, R.A.M.C., attached Lancashire Fusiliers.

Capt. E. A. Sanbrook, Australian A.M.C.

### DEATHS AMONG THE SONS OF MEDICAL MEN.

The following son of a medical man must be added to our lists of those who have fallen during the war:—

Second Lieut. R. M. Ross, Worcestershire Regiment, youngest son of Dr. D. M. Ross, of Brighton.

### THE HONOURS LIST.

The following awards to medical officers are announced:—

#### Bar to Military Cross.

Temp. Capt. Allen Coulter Hancock, M.C., R.A.M.C.

For conspicuous good work in advanced dressing-stations, notably when he successfully conducted evacuation of wounded under heavy shell-fire and adverse circumstances. Again, when the O.C. was wounded, Captain Hancock took command, and by his initiative, personal courage, and devotion to duty was responsible for the able carrying out of wounded through a barrage of shell-fire for six days. He was then severely gassed, but persisted in attempting duty until physically incapable.

(The award of the Military Cross was recorded in THE LANCET of Dec. 16th, 1916, p. 1034.)

#### Military Cross.

Temp. Lieut. George Cleverdon Hartley, R.A.M.C., attached East Surrey Regiment.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in assisting to rescue a wounded man from the open under very heavy fire.

### FOREIGN DECORATIONS.

#### By the King of Serbia.

Order of St. Sava, Fifth Class.—Capt. R. P. Nash, R.A.M.C.

Order of St. Sava, Third Class.—Major H. St. M. Carter, D.S.O., R.A.M.C.

Distinguished Service Medal.—Temp. Capt. R. Heaton, R.A.M.C.

#### By the King of Montenegro.

Silver Medal for Bravery.—Temp. Capt. D. O. Riddell, D.S.O., R.A.M.C.

#### By the Sultan of Egypt.

Order of the Nile, Third Class.—Col. J. Fallon, A.M.S.

**DOCTORS AND NATIONAL ORGANISATION.**—At the monthly meeting of the Royal Faculty of Physicians and Surgeons of Glasgow held on March 5th the following resolution, moved by Dr. J. McGregor Robertson, and seconded by Dr. John Brown, was approved:—

That the Royal Faculty of Physicians and Surgeons of Glasgow approves of the principle of the organisation of the whole nation to secure the successful and rapid conclusion of the war, so that all fit persons shall be liable to be called on by the Government to render such service in naval, military, or civil departments as they may be deemed suitable for, due regard being paid to age, training, and circumstances: if and when this proposal is carried into actual practice by the Government the Royal Faculty will be prepared to render all possible assistance in the organisation of their own profession.

## OBITUARY OF THE WAR.

JOSEPH ELLIS MILNE, M.A., M.D., C.M. ABERD., D.S.O.,  
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain J. E. Milne, who was killed in action in France on Feb. 22nd at the age of 48, was youngest son of Captain James Milne, a shipmaster, of Fraserburgh and Aberdeen. He was educated at Aberdeen Grammar School and

University, taking his M.A. degree in 1888 and his M.B., C.M. with honours in 1891. Setting up in practice in Aberdeen, he remained there until April, 1915, when he applied for a commission in the R.A.M.C. Within a few days of obtaining it he sailed for France with the Highland Casualty Clearing Station, becoming later medical officer to the King's Liverpool Regiment. He had his aid-post in the front trench, having made special request that no wounded man

should be removed from the place where he fell until he had seen him. And doubtless it was when thus engaged that Captain Milne received his own fatal injury.

Captain Milne was from his youth up a keen sportsman; in Aberdeen he was doctor to the Football Club; and in rest billets with his battalion he organised football teams. He was a shrewd observer of men, and never forgot a face he had once seen. Fearless himself, he was a strength to those he tended, whether in his exceptionally large practice at home or with the Irish lads at the front. In both spheres he leaves a blank. Captain Milne was unmarried.

THE LATE LIEUTENANT-COLONEL J. F. FLASHMAN,  
A.A.M.C.

Lieutenant-Colonel James Froude Flashman, whose death from pneumonia while on active service in France in his forty-seventh year we announced in an obituary notice last week, had for several years occupied the position of Government pathologist in the New South Wales Lunacy Department, lecturing on neurology at the University of Sydney. After leaving the Lunacy Department he practised in Sydney, where he held the appointments of honorary assistant physician and lecturer on clinical medicine at the Royal Prince Alfred Hospital and honorary physician to the South Sydney Hospital. At the outbreak of war he was Officer Commanding the University Scouts, and relinquished his command to join the Medical Corps for service abroad. Towards the end of last year he became a Member of the Royal College of Physicians of London. By his death Australia has lost a most promising member of the medical profession.

## WAR DISABLEMENT.

Following their last statement and recommendations on the physical treatment of disabled soldiers, the Section of Balneology of the Royal Society of Medicine has now reappointed a War Disablement Committee to advise in all medical matters connected with the treatment and re-education of disabled soldiers. A demonstration of measuring apparatus was given at a meeting of the section on March 8th. Dr. R. Fortescue Fox said that it was fortunate for France that a leading part in the direction of the treatment of disabled men was in the hands of two physiologists, Professor Camus and Professor Amar, whose methods were widely followed in the centres for treatment and training throughout France. Dr. Fox showed a variety of instruments in use at the Red Cross Clinic for the Physical Treatment of Disabled Officers, including protractors and arthrometers from the Grand Palais Hospital, as well as Professor Amar's cheirograph for measuring and recording the feeble pressure

of paralysed hands and his arthro-dynamometer. The exhibit also included goniometers and a torsion-meter for measuring supination and pronation, designed at the clinic. Dr. Sonntag, medical officer to the clinic, demonstrated an ergograph that he had designed for estimating and recording the power of muscular movements. All patients at the clinic are submitted to weekly measurements by one or more of these instruments. Dr. J. Campbell McClure communicated a paper by Mr. Roddie, who has charge of the manipulation baths at the clinic. The whole body may be treated by manipulation baths at about blood heat or single limbs at a much higher temperature (112° to 118° F.). The paper described the action and uses of such baths in increasing the mobility of muscles and joints and improving their nutrition.

## THE EMERGENCY SURGICAL AID CORPS.

At the annual general meeting of this corps, held at the house of the Royal Society of Medicine, Sir Rickman Godlee presided over a good attendance of members. The organisation now consists of three corps, a Metropolitan Police section with 108 members, a military section (Home Forces) with 62 members, and a naval section, which has been formed since the last general meeting, with 12 chief surgeons, 43 surgeons, and 13 anesthetists. Each section is equipped with an ample supply of all necessary surgical appliances packed in convenient boxes and has at its disposal, thanks to the Royal Automobile Club, a fleet of powerful motor-cars, while assistance is given by the General Omnibus Company and the Great Eastern Railway Company. The police section deals with any emergencies that may occur in the metropolis by reason of air raids or other risks to life in connexion with the war, the military section operates on the East Coast from Dover to the Wash, and the naval section is a reserve for assisting naval surgeons to deal with wounds brought into our ports at any point in the United Kingdom. In submitting the annual report Sir Rickman Godlee testified to the energy and labours of the executive committee, and stated that since the last meeting the rotas had been summoned 12 times, including the call to the scene of the explosion on Jan. 19th, when 103 members responded and 53 were sent to the scene of the disaster. The statement of income and expenditure showed that the receipts were £2349. 6d., and the disbursements £253 14s. 5d., and the chairman said that the executive committee would like to see the fund replenished and the deficit made good. Sir Arthur May, representing the Royal Navy, assured the corps of the great value which his department attached to it and the urgent need for its existence in case of necessity, although he hoped that necessity would never arise. Sir Thomas Gallwey, representing the Home Forces, said that but for the Emergency Corps he would not be able to state that the Home Forces were prepared for all contingencies, while Sir Edward Henry, representing the Metropolitan Police, in thanking the corps, said that it was very desirable that the public should know that air-raid relief-parties had been organised everywhere and that the co-operation of the emergency corps ensured that even a catastrophe greater in magnitude than any yet experienced could, in respect to the aid of injured persons, be well and promptly dealt with. Some discussion on questions of detail in connexion with emergency work having taken place, the executive committee consisting of Sir Rickman Godlee, chairman, Captain F. F. Burghard, R.A.M.C. (T.F.), Mr. A. H. Cheatle, Mr. Ernest Clarke, Mr. W. H. Clayton-Greene, Mr. E. M. Corner, Major W. McA. Eccles, R.A.M.C. (T.F.), Mr. G. J. Jenkins, Dr. H. M. McCrea, Mr. M. S. Mayou, Mr. J. W. Thomson Walker, Dr. Andrew Wylie, and Mr. J. Y. W. MacAlister, honorary secretary, were re-elected, the name of Mr. J. P. Lockhart-Mummery being added to the list.

THE HARVARD MEDICAL UNIT.—Dr. Hugh Cabot and Dr. George P. Shattuck, of Boston, U.S.A., with 14 doctors and 17 nurses, arrived in London last week *en route* to France to reinforce the Harvard University Unit which has charge of one of our general hospitals. The unit is under the command of Sir Alan Perry, who met the new detachment. Dr. Cabot and Dr. Shattuck have already served a term at the hospital. It was rightly felt in the United States that to brave the perils of submarines was a fine action, and the unit had an enthusiastic send-off at Boston.

**THE CONFERENCE SUMMONED BY MR. NEVILLE  
CHAMBERLAIN.**

The Conference summoned by Mr. Neville Chamberlain, the Director-General of National Service, to consider the organisation of the medical profession with a view to meeting the needs of the military and civil population in existing circumstances, was opened on March 14th. Sir Donald MacAlister, K.C.B., President of the General Medical Council, presided, and all the representatives summoned to the Conference were present—namely, Dr. T. Jenner Verrall, Mr. E. B. Turner, Dr. Buttar, Dr. Richmond, representing the Central Medical War Committee; Dr. Frederick Taylor and Sir Rickman Godlee, representing the Committee of Reference of the English Royal Colleges; and Dr. Norman Walker, Dr. J. C. McVail, and Dr. John Adams, representing the Scottish Medical Service Emergency Committee. The secretaries of these committees—namely, Dr. Cox and Mr. Bishop Harman, secretaries of the Central Medical War Committee, Mr. Hallett, secretary of the Committee of Reference, and Mr. T. H. Graham, secretary of the Scottish Medical Service Emergency Committee—were in attendance. The Conference was also attended by Sir William Babtie, V.C., representing the War Office; by Sir Arthur Newsholme and Mr. Stutchbury, representing the Local Government Board in England; and Sir Robert Morant and Mr. Smith Whitaker, representing the National Insurance Commission. The Conference did not conclude the important business brought before it and met again on March 15th. If the Conference should decide to advise the Director-General of National Service that compulsory powers must be obtained, there can, we think, be no doubt that legislation will be necessary. We believe that, from a preliminary survey of the position, the departments of the Government particularly interested have come to the conclusion that such legislation will be required.

**ACCOMMODATION FOR THE WOUNDED AT PORTSMOUTH.**—The Portsmouth board of guardians have prepared a scheme which will enable them to place 200 additional beds at the workhouse at the disposal of the war authorities. This will make about 600 beds which the board have provided for the wounded. They have also given consent for hospital tents to be put up in the grounds adjoining the present military blocks and for the erection of a shelter-hut on the roof of one of the wards. Any damage that may occur to the existing buildings is to be made good by the military authorities at the conclusion of hostilities.

**VOCATIONAL RE-EDUCATION OF THE BELGIAN WAR CRIPPLE.**—The Belgian Military Institute of Professional Re-education at Port-Villerz, near Vernon, combines facilities for medical treatment with a complete course of vocational re-education continued until the man is fully trained. Whilst in British institutions at the present time medical treatment rarely occupies more than an hour each day of the man's time, and his disabled part is re-educated for a small fraction only of the day, the training in the Belgian workshops ensures the movement of muscles and joints for several additional hours of the day. The cure of functional disability of limbs depends in large measure on the man's psychology, and the Belgian experience is that the interest of his work and the mental stimulus of seeing something made by his own efforts have appreciable value in his cure.

**THE LATE DR. PATRICK W. MAXWELL.**—The death occurred on Saturday, March 10th, at his residence in Dublin, of Dr. Patrick William Maxwell, one of the best-known ophthalmic surgeons in Ireland. He was only 61 years of age, but had been in unsatisfactory health for some time, and the death of his wife a year ago, and more recently that of his only son, who was killed in action, contributed to the sad end. Patrick Maxwell was a native of Glasgow and was educated at Edinburgh University, where he took the M.B. and M.C. degrees in 1880. After spending some time abroad he settled in Dublin, obtained the Fellowship of the Royal College of Surgeons in Ireland, and held various hospital appointments. He was aural and ophthalmic surgeon to Dr. Steevens' Hospital, Jervis Street Hospital, and to the Royal Victoria Eye and Ear Hospital, and surgeon-aurost in ordinary to the Lord Lieutenant during the vice-royalty of Lord Zetland. Of the three daughters who survive him one, Miss E. M. Maxwell, is a member of the medical profession, and is at present engaged in ophthalmic work at Malta.

## Parliamentary Intelligence.

### NOTES ON CURRENT TOPICS.

#### *Cocaine in Dentistry.*

The Committee appointed by the Home Secretary to inquire into the use of cocaine in dentistry has reported, and the report is signed by Sir CHARLES HOBBHOUSE and three of the four remaining members. The inquiry took its rise in certain opposition which developed to the terms of a regulation under the Defence of the Realm Act forbidding the sale of cocaine to, or its possession by, any except authorised persons. This interfered with the supply of the drug to unregistered dental practitioners, and pending the completion of inquiry, temporary relaxation of the regulation was granted to them in the form of permits. The Committee has now come to the following conclusions:

We are of opinion that while there is practically no evidence to show any prevalence of the cocaine habit amongst the people of this country, and only one case of the improper use of cocaine by unregistered dentists, yet, as a drug, it is so uncertain and so potentially dangerous in its uncertainty that some restriction should be placed on its possession and sale. Accordingly, we recommend: (a) That preparations of cocaine containing more than 1 per cent. of cocaine for use as local anaesthetics in connexion with dental work should be procurable only from registered chemists, or from persons or firms licensed for the purpose by the Home Secretary, and subject to the condition that such preparations should be used for dental purposes only. (b) That such preparations should only be procurable for use by registered dentists or members of a dental association, the conditions of membership of which have been approved by the Home Secretary. The above-mentioned classes will naturally be free to purchase all preparations not exceeding 1 per cent. strength. (c) That persons practising bona fide as unregistered dental practitioners, and who can so satisfy their local authority, should be entitled to apply for registration, for right to purchase preparations of cocaine containing not more than 1 per cent. of cocaine. Such authorisation to be granted by the county or borough council of the locality in which their business is situated, any refusal to register such persons being subjected to an appeal to the Home Secretary.

Professor W. M. BAYLISS is the member of the Committee who does not sign the report.

"The conclusion," he says in the course of a memorandum, "to which the evidence compels me to come is that, since the sale of cocaine is attended with serious risks to the community and is unnecessary in dentistry, there is no reason to interfere with the operation of Regulation 40 B of the Defence of the Realm Regulations, and I would venture to recommend that the permit which has been issued to unregistered dentists to obtain preparations of cocaine should not be continued for any further period of time."

#### *Criminal Law Amendment Bill.*

Further consideration has been given to the terms of Clause 2 of the Criminal Law Amendment Bill by a Grand Committee of the House of Commons. The clause prohibits sexual intercourse by a person suffering from venereal disease in a communicable form.

On Thursday, March 8th, Mr. GLYN-JONES moved an amendment so that the offence of soliciting or inviting by a person suffering from venereal disease should not extend to instances where the parties were husband and wife. Sir GEORGE CAVE, the Home Secretary, deprecated introducing an exception into the general language of the clause. The amendment was withdrawn.

Mr. RAWLINSON moved an amendment to the effect that a person suffering from the disease

Shall forthwith consult a duly qualified medical practitioner either at a hospital or otherwise, and shall take reasonable precautions to prevent the communication of such disease to other people.

He said that Lord Rhondda's Bill had now been introduced in the House of Lords, but it only provided that unqualified persons should not practise as regarded venereal disease. There was not a word in that Bill requiring infected people to consult a medical man. Therefore it would be well to deal with the matter in the Bill before them. People should be persuaded at once to consult a physician.

Mr. HAYES FISHER (Parliamentary Secretary to the Local Government Board), whilst hoping that the amendment would not be pressed, agreed that it was most desirable that a duly qualified medical man should be promptly consulted. That, indeed, was the whole policy of the Local Government Board, and arrangements were being made all over the country that proper treatment could be obtained gratuitously and secretly. That was being done on a purely voluntary basis. By this inducement it was hoped greatly to mitigate the disease. But the policy was one of inducement and not of punishment. If failure to consult a duly qualified medical practitioner was made a criminal offence, that would stifle the policy of the Local Government Board at once. It would be unwise to invoke too many penalties.

Sir W. COLLINS referred to the scope of Lord Rhondda's Bill and expressed disappointment at its limited character. He did not find in it any of the sanitary precautions with which it had been expected the Bill would deal. As to the amendment, he favoured education and not punishment.

After some discussion the amendment was rejected without a division.

It having been agreed that from Clause 2 there should be admitted Subsection 3, providing for the compulsory examination of persons convicted of certain offences, on Wednesday, March 14th, the Committee, acting on an amendment moved by Commander WEDGWOOD, omitted also Subsection 4, the force of which, it was admitted by the Home Secretary, had now disappeared. Sir WILLIAM COLLINS moved as an amendment to insert—

Every medical practitioner on becoming aware that any patient of his is suffering from venereal disease in a communicable form shall forthwith inform him thereof, and warn him against any action or neglect on his part which might render likely the communication of such disease to any other person.

The amendment had been put down on the assumption that Subsections 3 and 4 were to be kept in the Bill, and after some debate was withdrawn. A discussion took place on a proposal to insert in the clause a subsection securing the detention of a person convicted of an offence in the schedule to the Act, and certified to be suffering from venereal disease, until the disease may be no longer communicable. The Home Secretary opposed the suggestion, which was rejected. In Subsection 6 of Clause 2 the following definition of venereal disease was agreed upon: "Syphilis, gonorrhœa or soft chancre," necessary additions to the list, if any, to be made by statute.

#### HOUSE OF LORDS.

THURSDAY, MARCH 8TH.

##### *Venereal Disease Bill.*

Lord RHONDDA (President of the Local Government Board) moved the second reading of the Venereal Disease Bill, the purpose of which is to prevent the treatment of venereal disease otherwise than by duly qualified medical practitioners and to control the supply of remedies therefor. He said that it was hoped that the measure would very considerably reduce the ravages of venereal disease. He did not propose to emphasise in any detail the widespread character of the evil or the fell consequences of this terrible scourge on the health of the nation. At the same time he wished to guard himself against any suggestion that because of the unpleasant nature of the subject with which the Bill dealt it ought not to be discussed. On the contrary, he thought that the National Council for the Prevention of Venereal Disease were doing valuable work in trying to bring home to the people of this country the terrible consequences of this contagion. It was most important that all should be taught to shun any possibility of contagion just as they would shun deadly poison. The Bill was based mainly on the conclusions of the Royal Commission which reported last year, and the conclusions of that body must carry greater force than anything he could say on this subject. The Commission had not been able to arrive at exact figures, but the evidence led it to the conclusion that the number of persons affected with syphilis, acquired or congenital, could not fall below 10 per cent. of the population in large cities. Gonorrhœa must exceed that proportion. In connexion with the Royal Commission, all would be indebted to Lord Sydenham, the chairman, for the work he had done, and he would heartily welcome any assistance which he would be good enough to give in the passage of the Bill into law. If precise and definite figures regarding the disease existed they would not be a full measure of the very great evil. The reason why figures were not available was that there were a number of deaths arising from this cause which were not detected as such, or they were otherwise certified in order to avoid wounding the susceptibilities of relatives. Deaths due to general paralysis of the insane were mainly to be attributed to venereal disease. It was often a cause in locomotor ataxy and aneurysm of the aorta. Congenital debility in infants was often due to syphilis in the parents. It predisposed very largely to tuberculosis. In the case of cancer it often happened that the disease was started in an old sore. The evidence before the Royal Commission showed that it was the cause even of the death of children before their birth. It was estimated that a large percentage of sterility in women was due to gonorrhœa, and a common cause of the blindness in children was venereal disease of the parents. That amply proved the need for remedial measures.

##### *Urgency of Legislation.*

The urgency (Lord Rhondda proceeded) would be great at any time, but it was greater now when the nation was at war. History recorded this fact over several centuries that after every great war there was a great increase in the disease. The noble lord proceeded to quote from Sir Malcolm Morris to the effect that the great strides in medical knowledge during the last 10 years gave more hope and encouragement that something substantial could be done in mitigating the evil. He referred also to the discovery of salvarsan by Ehrlich. The disease could be brought under control, and might now be regarded as curable if treated in the early stages. The Local Government Board had been in communication with the county councils and county borough councils and had invited them to prepare

schemes of diagnosis and treatment in co-operation with hospitals and general practitioners. It had arranged for elaborate facilities for diagnosis, hospital treatment, treatment to all comers irrespective of residence, free and confidential, and for the free supply of drugs to general practitioners. The county councils were asked to provide 25 per cent. of the cost, and the Treasury had agreed to contribute 75 per cent. The present Bill was a corollary to the treatment in these centres already being arranged by the local authorities. *Prevention of Quack Treatment.*

The Bill was designed to prevent quack treatment of the disease. It prohibited treatment by unqualified persons, and also the sale or supply of any drug in this connexion except on the written prescription of a duly qualified practitioner. Clause 2 provided means for the Act being brought into operation in an area when the local authorities had provided for free diagnosis and free treatment. The Bill went rather beyond the actual recommendations made by the Royal Commission. The Commission did not actually recommend the suppression of unqualified persons, but it reported that the members had no hesitation in stating that the effects of unqualified practice were disastrous, and its continued existence was one of the principal causes in hindering the eradication of venereal diseases. He had had conversation with several members of the Commission, and he thought that they would have gone further in some of their recommendations to-day. The Commission had had regard to some practical difficulties, but some of these had been removed. He did not claim that the Bill was watertight, and it was possible that some of its provisions might be evaded by unscrupulous persons. On the other hand, it marked a very considerable advance and the moral effect should be great. Their lordships might wish to know how far the schemes of treatment and diagnosis had been carried out. Schemes prepared by county councils and borough councils had been submitted for districts covering in England and Wales a population of 23½ millions out of a total population of 36 millions. Of these, schemes covering a population of 16 millions had been provided. In half the country, therefore, there was provision for free diagnosis and treatment. The practical difficulties which the Commission had in mind had been removed.

##### *An Uncontroversial Measure.*

The Bill (Lord Rhondda hoped) would be regarded as an uncontroversial measure. No doubt it would press a little hardly on druggists and chemists, but he had every confidence in believing that the pharmaceutical body as a whole would offer practically no opposition to the measure. It would, no doubt, interfere to some extent with the livelihood of herbalists, but after hearing from a deputation what they had to say he saw no reason to change his view that he ought to stand firmly for having no exception made with regard to them. Their Lordships might consider the Bill rather a mild measure for so great an evil, and he apprehended that any criticism which they might make would be towards the omissions in the Bill rather than on what it contained. There was a considerable body of opinion in the country which favoured compulsory notification. He approached that point with a perfectly open mind. He gave it every possible unprejudiced consideration, and he came to the conclusion that the Bill was not closing the door to some modified form of compulsory notification later on. For the present Parliament should give a fair trial to the action which was being taken by the local authorities, and it would prejudice that fair trial if compulsory notification were introduced now. Compulsory notification might endanger the new scheme of treatment, as it would encourage persons to conceal the presence of the disease. He hoped that after the Bill passed through the House of Lords it would be sent by the House of Commons for consideration to the Grand Committee which was considering the Criminal Law Amendment Bill.

Lord SYDENHAM, as Chairman of the Royal Commission on Venereal Disease, welcomed the Bill. There was abundant evidence brought before the Commission to prove that the treatment of venereal diseases by quacks and by quack remedies had been disastrous in the extreme. It was vitally important that these diseases should be treated in the very earliest stages. The noble lord drew attention at some length to the evils arising from quack remedies and quack treatment. The Commission was impressed with the evils of unqualified practice, but it did not like at the time when it reported to recommend legislation for the suppression of quacks, feeling that that ought to come when free and ample treatment was made for all classes. The Bill was a considerable step in advance.

Lord GAINFORD, speaking from his experience as President of the Board of Education (an office which, as Mr. J. A. Pease, he held before his elevation to the peerage), referred to the tragic sufferings which many children endured as the result of venereal disease in their parents.

The Bill was read a second time. The Venereal Disease Bill passed through Committee on Tuesday, March 13th, without amendment or comment.

## HOUSE OF COMMONS.

WEDNESDAY, MARCH 7TH.

## Nurses' Registration.

Mr. MACCALLUM SCOTT asked the Parliamentary Secretary to the Local Government Board whether, before any Bill for the State Registration of Trained Nurses was introduced, an opportunity would be given to the organised societies of nurses in England, Scotland, and Ireland to make representations to the Government.—Mr. HAYES FISHER replied: Full consideration will be given to any representations made by organised societies of nurses before the Government introduces any Bill for the State registration of nurses.

Mr. DUNDAS WHITE: Will they be given an opportunity of presenting their views personally by deputation?—Mr. HAYES FISHER: I will consider that.

Mr. RENDALL: Is it the intention of the Government to introduce a Bill of this kind?—Mr. HAYES FISHER: That is a matter that is still undergoing consideration.

THURSDAY, MARCH 8TH.

## Treatment of Disabled Soldiers in Scotland.

Answering Mr. DUNCAN MILLAR, Mr. BARNES (Minister of Pensions) said: When I discussed the whole subject of the treatment and training of disabled soldiers at a conference of the Provosts of Scottish towns at Glasgow recently, it was arranged that the matter should be considered for Scotland as a whole by them. In the meantime various proposals had been made by local committees. Among these we may mention the provision of a hospital for cases of paralysis at Ralston House, near Glasgow, and the use of the Hairmires Colony, near Lanark, for tuberculous cases. In Edinburgh the Royal Colleges of Physicians and Surgeons have undertaken the medical examination of cases for the local committees, and a joint committee of the Colleges is now considering arrangements for the medical treatment of discharged men. I am taking steps to arrange a conference of local committees with the object of securing the acceptance of a scheme for the whole of Scotland.

MONDAY, MARCH 12TH.

## Free Treatment of Venereal Diseases.

In reply to Mr. ROWNTREE, Mr. HAYES FISHER, Parliamentary Secretary to the Local Government Board, wrote: Twenty local authorities in England have already provided facilities for the free treatment of venereal diseases in 28 hospitals. These facilities are also available for the treatment of persons residing in other areas. The Local Government Board has approved the schemes of 24 other authorities for the provision of free treatment, and the facilities afforded by these schemes will be available shortly. In addition, the Board has under consideration further schemes submitted by 44 local authorities. It is not yet possible to supply any statistics as to the number of persons who are applying for treatment at the hospitals where facilities are already available.

## Infant Mortality.

Answering Mr. W. THORNE, who asked for statistics as to infant mortality in certain borough areas, Mr. HAYES FISHER wrote: The figures are:

	Deaths of infants under 1 year per 1000 births.			Deaths of infants under 1 year per 1000 births.			
	1914	1915	1916	1914	1915	1916

TUESDAY, MARCH 13TH.

## Medical Classification of Attested Men.

Replying to Mr. MACCALLUM SCOTT, who asked whether any decision had yet been reached as to the new instructions with regard to attested men rejected on re-examination and as to the new form of medical classification certificate, Mr. MACPHERSON (Under Secretary for War) said: It is intended to modify the present instructions and to issue a new form of medical classification certificate, but the new form and instructions have not yet been issued.

## Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An ordinary meeting of the Council was held on March 8th, Sir W. Watson Cheyne, the President, being in the chair. A report was read from Mr. H. C. Golding-Bird on the proceedings of the Central Midwives Board during the past year. The Council placed on record their high appreciation of Mr. Golding-Bird's services as the representative of the College on the Central Midwives Board, and directed that the grateful thanks of the Council be conveyed to him for the very efficient manner in which he has fulfilled the duties associated with that office during the last eight years. Mr. H. J. Waring was elected as the representative of the College on the General Medical Council in the vacancy occasioned by the retirement of Sir Henry Morris. The Council resolved that they should place on record their great appreciation of the services of Sir Henry Morris in acting as the representative of the College on the General Medical Council for 13 years. The President reported the delivery of the Hunterian Oration by Surgeon-General Sir George H. Makins, K.C.M.G., A.M.S. The best thanks of the Council were given to Sir George Makins for his oration, and he was requested to publish it. In response to a request from the secretary of the National Medical Union, it was resolved that the President should receive a deputation from that body to confer with him on the subject of the mobilisation of the medical profession. Licences to practise dentistry were conferred upon 11 candidates (including one woman), who have passed the necessary examinations and have complied with the by-laws. The following are the names and dental schools of the successful candidates:

Cyril Charles Becker, Guy's Hospital; Eric Bottomley, Leeds University; George Harold Danks, Guy's Hospital; Thomas John Davies, London Hospital; Francis Malcolm Timothy Flintan, Middlesex and Royal Dental Hospitals; Florence Goodman, University College Hospital; Clifford Morley John, Bristol University; Aubrey Thompson Madin, Birmingham University; David Errand Robinson, Guy's Hospital; Alfred Williams, Bristol University; and Robert Wolff, B.Sc. Cape Town, Middlesex and Royal Dental Hospitals.

UNIVERSITY OF BRISTOL.—At the Second Examination for the degrees of M.B., Ch.B., the following candidates were successful:—

Hilda Mary Brown, Sukhasagar Datta, Marjorie Smith Neville, and Thomas Henry Algernon Pinniger.

At the Third Examination for the Diploma in Dental Surgery William Holder Shipway was successful.

THE Wellcome Historical Medical Museum will be closed from April 1st to the 30th, inclusive, for cleaning.

Mr. Leslie Pearce Gould, M.A., M.Ch. Oxford, F.R.C.S. Eng., has been elected Radcliffe Travelling Fellow at Oxford for 1917-20. He is the son of Sir Alfred Pearce Gould.

THE honorary treasurer of Queen Mary's Convalescent Auxiliary Hospitals, Roehampton, has received £1000 from the Executive Committee of the Saskatchewan branch of the Canadian Red Cross Society for a year's maintenance of a ward in these hospitals.

ROYAL MICROSCOPICAL SOCIETY.—The next meeting of this society will be held on Wednesday, March 21st, at 8 P.M., when Mr. Kenneth Goadby will communicate "Bacteriology of War Wounds."

CHARITY ORGANISATION SOCIETY.—The third of a series of lectures on social subjects will be held at 34, Queen Anne's Gate, S.W., by invitation of Lady Glenconner, on Wednesday next, March 21st, at 3.30 P.M. Dr. F. N. K. Menzies, Principal Assistant Medical Officer to the London County Council, will give an address on the Prevention of Consumption.

THE LATE ROBERT ROXBURGH, M.B. EDIN., F.R.C.S. EDIN., J.P.—Dr. Robert Roxburgh, who died at his residence at Weston-super-Mare, on Feb. 16th, graduated as M.B. Edin. in 1876, taking the F.R.C.S. Edin. in 1880. He had practised in Weston for many years, and was honorary physician to the Weston-super-Mare Hospital and consulting physician to the Royal West of England Sanatorium. He was held in high esteem in Weston, and his efforts in promoting every good public and sanitary work in that town will be gratefully remembered by his numerous friends and patients.

MEDICAL WOMEN'S FEDERATION.—The first general meeting of the Medical Women's Federation will be held at the rooms of the Medical Society of London, 11, Chandos Street, Cavendish-square, W., on Friday next, March 23rd, at 3 P.M. At this meeting a statement will be made as to the

history, aims, and objects of the Federation, after which the following resolution will be discussed and then put to the meeting:—

That this meeting heartily approves of the Medical Women's Federation and pledges itself to support it by every means within its power.

The election of officers will follow. Dr. Jane Walker is acting as honorary secretary *pro tem.* to the Federation.

THE PROFESSORSHIP OF CHEMISTRY IN QUEEN'S UNIVERSITY, BELFAST.—The Chair of Chemistry in the Queen's University of Belfast has become vacant through the resignation, owing to declining health, of Dr. E. A. Letts, who has held the position since 1879.

## Appointments.

*Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

HIME, ALFRED ERNEST BARRATT, L.R.C.P., M.R.C.S., D.P.H., has been appointed Medical Officer to the Rhode Hill V.A.D. Hospital, Uplyme, Devon.

KIRKMAN, ALBERT HENRY BRAUMONT, F.R.C.S. Edin., M.R.C.S., L.R.C.P., Medical Officer and Public Vaccinator for the Axmouth District by the Axminster (Devon) Board of Guardians.

LISTER, T. D., M.D., B.S. Lond., Consultant for Chest Cases to the Prince of Wales's Hospital for Officers, Marylebone-road, W. (Great Central Hotel).

NEWLAND, F. C., Certifying Surgeon under the Factory and Workshop Acts for the Cleobury Mortimer District of the county of Salop.

PRIDHAM, W. F., M.R.C.S., L.R.C.P., L.S.A., Medical Officer of Health for Great Torrington (Devon).

RAMSDEN-WOOD, WILLIAM EDWARD, M.A., M.D. Cantab., F.R.C.S., M.R.C.P. Edin., Representative on the Devon Voluntary Association for the Care of the Mentally Defective.

BOY, D. W., M.B., B.C. Cantab., F.R.C.S. Eng., Physician to Out-patients at the General Lying-in Hospital, York-road, Lambeth, S.E. SQUIRE, J. E., F.R.C.P., and WHITE, W. H., F.R.C.P., Consulting Physicians to the Marylebone General Dispensary.

WEBB, C. H. S., M.B., B.S. Lond., Assistant Surgeon to the Middlesex Hospital.

WILLIAMS, SYDNEY RICE, M.B. Lond., L.R.C.P., M.R.C.S., Temporary Medical Officer of Health for the Ashburton (Devon) District Council.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.*

BIRKENHEAD UNION INFIRMARY.—Junior Female Resident Assistant Medical Officer. Salary at the rate of £300 per annum, with board, &c.

BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £250 per annum, with apartments, &c.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Female House Surgeon. Salary £200 per annum.

BOLTON UNION, FISHPOOL INSTITUTION, Farnworth, near Bolton.—Resident Assistant Medical Officer. Salary £383 5s. per annum, with rations, &c.

BRENTFORD ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.

BURY INFIRMARY.—Junior House Surgeon. Salary £150 per annum, with board, &c.

CAMBRIDGE, COUNTY MENTAL HOSPITAL.—First Assistant Medical Officer. Also Junior (Second) Assistant Medical Officer, unmarried. Salaries £300 and £200 respectively, with board, &c.

CARLISLE, CUMBERLAND INFIRMARY.—House Surgeon. Salary £200 per annum, with board, &c.

COLCHESTER, ESSEX COUNTY HOSPITAL.—Female House Surgeons.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant House Surgeon, unmarried. Salary £150 per annum, with board, &c.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.—Clinical Assistants in Out-patient Departments.

GRIMSBY COUNTY BOROUGH.—Temporary Female Assistant Medical Officer. Salary £350 per annum.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £250 per annum, with board, &c.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.

IPSWICH, EAST SUFFOLK AND IPSWICH HOSPITAL.—Female Resident Officer.

KENSINGTON AND FULHAM GENERAL HOSPITAL, Earl's Court, S.W.—Resident Medical Officer. Salary £150 per annum.

KENT EDUCATION COMMITTEE.—Ophthalmic Surgeon.

LIVERPOOL, DAVID LEWIS NORTHERN HOSPITAL.—House Surgeon for six months. Salary at the rate of £150 per annum, with board, &c.

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Two House Surgeons for six months.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—House Surgeon. Salary £50 per annum.

MANCHESTER, BAGLEY SANATORIUM FOR TUBERCULOSIS.—First Assistant Medical Officer, unmarried. Salary £300 per annum, with board, &c.

MANCHESTER CORPORATION.—Assistant Tuberculosis Officer. Salary £250 per annum.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road.—House Surgeon. Salary £120 per annum, with board, &c.

METROPOLITAN HOSPITAL, Kingsland-road, E.—Temporary Medical Officer for the Tuberculosis Dispensary.

NORWICH, NORFOLK AND NORWICH HOSPITAL.—Two House Surgeons. Salary £400 per annum, with board, &c.

OLDHAM ROYAL INFIRMARY.—First House Surgeon. Salary £250 per annum. Also Second House Surgeon. Salary £250 per annum. Also Third House Surgeon. Salary £200 per annum. With board, &c.

PETERBOROUGH INFIRMARY.—House Surgeon. Salary £150 per annum for first six months, £200 after, with board, &c.

PLAISTOW FEVER HOSPITAL, E.—Female Resident Medical Officer. Salary at rate of £250 per annum, all found.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Surgeon and Casualty House Surgeon for six months. Salary £120 per annum, with board, &c.

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford.—House Surgeon.

READING, ROYAL BERKSHIRE HOSPITAL.—House Surgeon for six months. Salary £250 per annum, with board, &c.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Female Senior Obstetric Assistant. Salary £33 per annum, with board, &c. Also to attend at Endsleigh-street Maternity Hospital. Salary £60 per annum.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, S.E.—Temporary Honorary Assistant Physician.

SALFORD ROYAL HOSPITAL.—Junior House Surgeon. Salary at rate of £150 per annum, with board, &c.

SHEFFIELD ROYAL INFIRMARY.—House Physician. Salary £120 per annum, with board, &c.

SHERESBURY, SHIRLETT SANATORIUM.—Temporary Assistant Officer.

Salary £300 per annum, with board, &c.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician and Junior House Surgeon. Salaries £150 and £120 per annum respectively, with board, &c.

TRURO, ROYAL CORNWALL INFIRMARY.—House Surgeon. Salary £150 per annum, with board, &c.

WARRINGTON INFIRMARY AND DISPENSARY.—Senior and Junior House Surgeons. Salary £200 and £150 per annum respectively, with board, &c.

WILTSHIRE COUNTY COUNCIL GENERAL EDUCATION COMMITTEE.—Dental Surgeon. Salary £250 per annum.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL.—Resident Medical Officer. Salary £300 per annum, with board, &c.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Resident Medical Officer or House Surgeon. Salary at rate of £150 per annum, with board, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Glynneath (Glamorgan); and at Gravesend (Kent).

## Births, Marriages, and Deaths.

### BIRTHS.

DOWNS.—On March 12th, at Palmers, Marlow-on-Thames, the wife of Dr. G. E. Downs, of a son.

EVANS.—On March 7th, Dorothy, wife of Arthur Evans, M.S., F.R.C.S., of Devonshire-place, W., of a son.

TATTERSALL.—On March 8th, at Beachy, Neath, South Wales, to Marnie and Captain Norman Tattersall, R.A.M.C.—a son.

WHELDON.—On March 3rd, at Abbeville-road, Clapham Park, S.W., to the wife of George Wheldon, L.D.S., Temporary Lieutenant, R.A.M.C.—a son.

### MARRIAGES.

BROOME—HARVEY.—On March 6th, at Bradling Parish Church, I.W., Frederick Charles Sedgwick Broome, Surgeon, R.N., to Mona Kathleen, youngest daughter of Mr. and Mrs. John Ginnes Harvey, Bradling.

CARTE—FOSTER.—On March 8th, at Holy Trinity Church, Cambridge, Geoffrey W. Carte, Surgeon, R.N., to Georgina, daughter of Captain Michael Foster, M.D., F.R.C.P.

FARNFIELD—WINDSOR-WATSON.—On March 7th, at All Souls', Hastings, John Stewart Farnfield, M.R.C.S., L.R.C.P. Lond., to Annabel Windsor-Watson, widow of John Watson, solicitor, Liverpool.

LEWIS—MANSFIELD.—On March 3rd, at St. Saviour's Church, London, Lieutenant-Colonel Rowland Philip Lewis, R.A.M.C., Wales, to Muriel Mary, only daughter of the late Edmund C. Mansfield, Ardrammon House, co. Donegal.

STRATON—ROBERTSON.—On March 7th, at St. Matthew's Church, Ealing, Arthur Arbutnot Stratton, M.D., F.R.C.S., Temp. Captain, R.A.M.C., to Mabel, third daughter of Mr. and Mrs. James Robertson, of Warwick-road, Ealing.

### DEATHS.

BEATLEY.—At St. Mary's terrace, Newcastle-on-Tyne, William Cramp Beatley, M.D., in his 61st year.

INMAN.—On March 11th, at Bournemouth, of heart failure, resulting from an acute pneumococcal infection, Dorothy Marguerite, beloved wife of A. C. Inman, M.A., M.B. Oxon, Superintendent of Laboratories, Brompton Hospital, London, Temp. Hon. Capt. R.A.M.C., and only child of Dr. and Mrs. Wethored, of 83, Harley-street, London.

MURDOCH.—On March 9th, at Fruids Park, Annan, Dumfriesshire, William Murdoch, M.D. Edin., aged 62 years.

RAWES.—On March 6th, at a nursing home in London, William Rawes, F.R.C.S. Eng., M.D. Durh., of St. Luke's Hospital, City-road, aged 55 years.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

### ICELAND MOSS.

A GERMAN professor has recently suggested using Iceland moss for mixing with flour to make bread. The following account of the use of this substance will be found in "A History of the Vegetable Kingdom" (1857), by William Rhind, then lecturer on botany, Marischal College, Aberdeen:—

Iceland moss (*Lichen islandicus*) is used as an edible substance by the Icelanders, who rarely obtain corn bread, and whose limited stock of substitutes obliges them to have recourse to every species of vegetable production, which is permitted by their inclement climate to spring forth. The plant is collected by the inhabitants of this northern region; and after being washed, is either cut into pieces, or it is dried by the fire or in the sun, then put into a bag which is well beaten. It is ultimately worked into a powder by being trampled on, and in this state is used as food. This lichen is found growing on the mountains both in the lowlands and highlands of Scotland. It consists of upright leaves nearly 2 inches high; soft and pliant when moist, but rigid when dry. They are smooth and shining, inclining to a red colour towards the roots, and having the exterior surface sprinkled with very minute black warts. The margins are set with small short stiff sporules. This lichen contains a nutritious matter called lichen-starch, along with a bitter principle. It is demulcent and tonic. When boiled and macerated in water it forms a nutritious and light jelly, which, with the addition of sugar and milk, has been used as a dietetic medicine in cases of decline, and was fancied at one time as a cure for consumption.

The name is now *Cetraria islandica*. In Germany it is said to be used for dressing the warp of webs in the loom. The jelly has also been mixed with wine as a nutrient drink. The moss is now said to contain cetrarin 3 per cent., lichenin 45 per cent., amyloaceous fibrin 36 per cent., gum 4 per cent., non-crystallisable sugar 4 per cent., water and salts (inorganic) 8 per cent. Lichenin is a starch-like body. The component parts, according to the analysis of Berzelius, are as follows: Bitter extractive 3·0, lichen-starch 44·6, sugar 3·6, gum 3·7, yellow extractive 7·0, green wax 1·6, tartar, tartrate of lime, and a little phosphate of lime 1·9, starchy fibre 36·2, trace of gallic acid. Dr. Spencer Thomson in 1852 said that—

It has been estimated that a ton of Iceland moss contains about as much nutritive matter as half a ton of wheat. The Saxon Government published a report upon this subject a few years ago, in which we are informed that 6 pounds 11 ounces of lichen meal, boiled with 14 times its quantity of water, and baked in this state with 39½ pounds of flour, produced 111½ pounds of good household bread. Without this addition the flour would not have produced more than 78½ pounds of bread, consequently the addition of 6 pounds 11 ounces of lichen meal occasioned an increase of above 32 pounds of good bread.

This increase was owing, of course, to additional water.

The use of the moss in phthisis was first established in Vienna and then admitted into the *materia medica* of the Edinburgh Pharmacopœia. London, however, did not much credit its virtues as a medicine. 1½ ounces of the lichen were boiled in a quart of milk not longer than a quarter of an hour over a slow fire. A teacupful was directed to be drunk frequently in the course of the day.

A German description runs as follows:—

After the bitter taste, which is found in the outer layer of the thallus, is got rid of by means of washing in weak potash solution, the result is the sweet Iceland moss (*Lichen islandicus ab amarisita liberatus*).

In Germany it is plentiful in the Fichtelgebirge, a mountain system of north-east Bavaria and in the Harz mountains and Tyrol. The composition is described as Flechtenstärke (Lichenin) and Flechtenbitter (Cetrarin).

### LETTERS FOR THE LONDON POSTAL AREA: NEW METHOD OF ADDRESS.

THE Postmaster-General has issued an appeal to the public in London and to their correspondents in the provinces to "adopt a simple system which will improve the postal service at the cost of very little trouble to themselves," thereby helping to save labour and money, which the country requires for war services. Under the system referred to the 112 separate delivery offices in London are each assigned a number to be added to the particular district in which they are situated. This, it is claimed, will materially assist the present staff of inexperienced Post Office sorters to relegate correspondence to its proper destination. The public are invited to observe the following method of addressing letters, parcels, and other postal packets for any house in the London postal area: 1. Name of addressee. 2. Number (or, if there is no number, the name) of the house. If there is a number as well as a name, the number should always be used. 3. Name of street or road in which the house is situated. 4. Initials of the postal district, followed by the number of the office of delivery. 5. The word "London"

if the place of posting is outside the London area. It will be immaterial, the Postmaster-General says, whether the name of the sub-district—e.g., Hampstead, Blackheath, Kensington—is inserted, omitted, or wrongly stated, as these will be ignored. We suggest that any omission to the fullest possible address may lead to confusion, how widespread we do not pretend to know. In the "Official List of Principal Streets," which can be obtained gratis at any post office, we find Queen-street, Mayfair, and Queen-street, Edgware-road, are both in the same delivery office, W. 1; and Prince's-road, South Wimbledon, and Prince's-road, Wimbledon Park, are both in delivery office S.W. 19. Under the new arrangement the address of THE LANCET Office is 423, Strand, W.C. 2, with the addition of the word "London" for correspondence from the provinces.

### BOVRIL PICTURES: "THE DUEL."

In connexion with their "Picture Scheme" Messrs. Bovril, Limited, of Old-street, London, have sent us a handsome framed engraving, size 40 × 30 in., after a picture by Mr. Cadogan Cowper, A.R.A., and signed by the artist. The picture, which has been excellently reproduced on India paper by Messrs. C. W. Faulkner and Co., represents a pair of duelists engaged in a resolute bout, apparently for the favour of a lady who stands in the foreground with a look of dismay depicted on her countenance. The subject of the picture is the outcome of the dream of a well-known Member of Parliament, when sleeping in the room in which, it was afterwards discovered, such an encounter as is depicted actually took place. This is the expected sequence of events when one dreams in panelled chambers, and Mr. Cowper has rendered the carved oak panelling over the old-fashioned fireplace with great dexterity as a background to his vigorous fighters. Altogether the engraving is well up to the standard of its predecessors in this series, and that standard is a high one.

### PREMIUMS OF OLD-TIME MEDICAL APPRENTICES.

APPRENTICESHIP in the medical profession is a thing of the past. There are no indentures now, though some medical men are still alive who were once apprentices serving under a master after indentures had been signed. At the Royal College of Surgeons of England there are three apprenticeship books kept, one recording the payment of the orphan's tax of half-a-crown and the other two (1745-1846) containing lists of apprentices and masters. The last entry in these books is dated April 24th, 1846, and records the fact that George Tertius Talbot had paid Mr. Joseph Henry Green, of Lincoln's Inn-fields, the sum of £315 as an apprentice who was "not to board." Joseph Henry Green was President of the Royal College of Surgeons of England in 1849 and 1858, and a very important person in the medical world, so that he could demand a stiff fee for indentures, but some of the premiums paid previously to that date were very high. The record was reached in January, 1826, when the sum of £1050 was paid to Frederick Tyrrell on behalf of or by William Tice James. Again, in 1830 £1050 was paid by or for James Dixon to the same eminent surgeon. On Dec. 2nd, 1825, John Alexander Harper's premium to Aston Key is £1000. £800 was paid for Thomas Egerton to William Money, and for William Pennington to Edward Stanley, of Lincoln's Inn-fields, £700, both in 1822. The last is a frequently occurring sum, as is also £600. But the regulation fee paid to a great surgeon on the staff of a hospital by a student anxious for a corner of his mantle, or something more than crumbs from his table, appears to have been 500 guineas. Such a sum we find repeatedly paid to Green, Abernethy, Earle, Stanley, and other College Presidents. A frequent sum, where lesser men are the masters, was £199 10s., but the sums ranged very widely. As a rule, sons were indentured to their fathers for the nominal sum of 5s., or no fee was paid. A certain James Saner, of Finsbury-square, several times received 5s. Others—famous surgeons—took varying premiums. Thus Bransby Blake Cooper took John Henry Roberts for 5s. in 1829, the year after the famous case of Cooper versus Wakley, when Cooper's reputation as a surgeon may have been damaged. Immediately afterwards, however, Cooper's fee rose to £500 received from one John Clement, and continued high as far as the record runs. Samuel Solly was taken by Benjamin Travers for 500 guineas, but Solly himself in 1834 charged £630 to an apprentice.

In the eighteenth century fees were smaller. They did not rise above £400, till in 1770 (May 3rd) £725 was paid by Charles Griffith to William Sharp. Henry Cline and William Blizzard were paid premiums of £300 in 1783, but Blizzard, who was President of the College in 1822, charged £500 in 1787. James Earle charged £315 in 1794, and the pupil "finds board, &c." On Nov. 4th, 1784, £500 was paid for Astley Cooper to William Cooper, but Sir Astley Cooper took no premium from Edward Cock in 1822, nor from Bransby Blake Cooper just 100 years ago. These were members of his family, and the famous Sir Astley Cooper was attacked

in an early issue of THE LANCET for nepotism. His conduct was defended by Sir James Scarlett in the case of Bransby Cooper v. Wakley on the obvious ground that a man was more likely to trust members of his own family than outsiders.

## THE PRICE OF FISH.

An article which appeared recently in the *Daily Mail* advocated as a form of National Service the institution of volunteers for fishing. The suggestion is interesting. The numbers of boats and men available now for the "harvest of the sea" are doubtless known to those most concerned, and a proposal of this kind would naturally be dependent upon factors familiar to the authorities. That there was a harvest may be seen by recalling that at the end of the season 12 years ago the catch of herrings officially stated at Yarmouth alone amounted to 535,378,800 herrings, 700 boats being engaged, and after curing them in the Scotch method, Yarmouth sent to Germany and Russia 239,496 barrels; and Lowestoft, a few miles away, sent to the same places 102,460 barrels, a grand total of 341,956 barrels. On this occasion the "Scotch lassies" came down from the North to pack them.

Much information that is of highly practical importance to-day will be found in a book published in 1908 on "The Romance of the World's Fisheries," by Sidney Wright (Seeley and Co., Ltd., London). With reference to mussels, the author says:

But why "go after" mussels when so many millions of them are to be picked from rocks, breakwaters, and mud or shingle-banks? The question is reasonable enough, though it would never be asked by anyone who had the least idea as to the number of mussels that are used in the United Kingdom alone every year. Hundreds of thousands, not of mussels, but of tons of mussels, are gathered annually and sold; and, absurd as it may sound, there is little difference between the profits made on them and those derived from the oyster fishery. To France alone the Belgians export over twelve million francs' (half a million pounds') worth every year. Then who are the consumers? The ground, in the first place; all the small mussels, and those which may have been tainted with sewage or poisoned by the copper bottoms of ships, are sent away by the barge-load for manure, or for lightening heavy clay soil. Secondly, the poor. Apart from those mussels that are eaten from choice, or those which the fisher-people out of work are sometimes glad to make a dinner of, many tons of them are eaten by the London poor alone every winter; buying them at a penny a quart, a family can have a meal for twopence. Even then we have not accounted for a third of the numbers given above. The prime mussels are required as bait for fine-fishing, and are sold at the rate of rather less than £2 a ton (over 51,000 fish go to the ton). Many fishing boats' crews use over 4 tons per boat in a month in this manner.

Referring to whelks, he states that these fish are a favourite food among the fisher people, and from the fact that a man will often do a hard day's work on nothing else they must needs be nourishing. The proportionate cost and nutriment of these small shell-fish have recently been debated in the press.

## VITAL STATISTICS OF BRITISH HONDURAS.

The Colonial Office has issued a report on the Blue-book of British Honduras for the year 1915. It gives the estimated mean population for the year as 41,928—21,041 males and 20,887 females. The death-rate was 26·2 per 1000 of population, compared with 28·1 in 1914. As usual, the principal cause of death was malarial fever. The birth-rate was 40·092 per 1000. The number of illegitimate births was 695 out of a total of 1681, or 41·35 per cent. The daily average number of patients under treatment and care in Belize Hospital was 40·73, in Corozal Hospital 4·96, in Orange Walk Hospital 4·85, in Stann Creek Hospital 8·2, in Punta Gorda Hospital 9·10, in Belize Lunatic Asylum 70·31, and in the poorhouse 35·82. The average rainfall for the ten years 1906-1915 in Belize was 85·16 inches, the maximum (130·93 inches) being in 1911 and the minimum (63·76 inches) in 1910. The average number of days on which rain fell during the ten years was 127.

P.N.—The term "Bipp" was given by Professor Rutherford Morison to Bismuth subnitrate, Iodoform, and Paraffin Paste, the use of which in the treatment of wounds was described in THE LANCET of August 12th, 1916, p. 268. A paper by Dr. Louise Garrett Anderson and Dr. Helen Chambers was published in THE LANCET of March 3rd, 1917, giving an account of this treatment at the Military Hospital, Endell-street, W.C., with a note on the bacteriological and chemical qualities of the paste by Dr. Chambers and Mr. J. N. Goldsmith.

Dr. M. L. (Paris).—An article on the subject appeared in THE LANCET of May 7th, 1910, entitled "The Use of Solid Carbon Dioxide," by Edward Reginald Morton, M.D., F.R.C.S. A book on the subject was reviewed in THE LANCET of Feb. 14th, 1914, entitled "Carbon Dioxide Snow," by J. Hall-Edwards, L.R.C.P. Edin., F.R.S. Edin. (London: Simpkin, Marshall, Hamilton, Kent, and Co. Pp. 78. Price 3s. 6d.). Aerators, Limited, Upper Edmonton, London N., some years ago issued an illustrated explanatory pamphlet entitled "Prana" Carbon Dioxide Snow Apparatus."

## Medical Diary for the ensuing Week.

## SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

TUESDAY.—Paper:—Dr. J. C. Mottram and Dr. S. Russ: Observations and Experiments on the Susceptibility and Immunity of Rats towards Jensen's Rat Sarcoma (communicated by Prof. H. G. Plummer).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, March 20th.

GENERAL MEETING OF FELLOWS, at 5 P.M.  
Ballot for Election to the Fellowship.

## MEETINGS OF SECTIONS.

Thursday, March 22nd.

NEUROLOGY (Hon. Secretaries—H. Campbell Thomson, C. M. Hinds Howell): at 8 P.M.  
A CLINICAL MEETING will be held at the National Hospital, Queen-square, Bloomsbury.

Friday, March 23rd.

STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—A. S. Blundell Bankart, H. A. Cockayne, C. P. Lapage): at 4.30 P.M.  
Cases:

Dr. H. C. Cameron: Amyotonia Congenita.

Dr. E. Caughey: Splenic Enlargement.

Papers:

Dr. H. C. Cameron: Status Lymphaticus from the Clinical Stand-point.

Major Hunter, C.A.M.S.: A Remarkable Condition of Development occurring in Two Brothers.

MEDICAL SOCIETY OF LONDON, 11, Chandos-st., Cavendish sq., W.

MONDAY, THURSDAY AND FRIDAY.—8.30 P.M., Lettsomian Lectures:—

Col. C. Wallace, A.M.S., C.B.: War Surgery of the Abdomen.

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Paper:—Capt. A. Innes, R.A.M.C. (T.): Pomphigus Acutus in the Anglo-Egyptian Sudan.

ROYAL STATISTICAL SOCIETY, Rooms of the Royal Society of Arts, John-street, Adelphi, W.C.

TUESDAY.—5.15 P.M., Paper:—The Right Hon. the Earl of Dunraven, K.P., C.M.G.: How to Improve our Fishing Industries.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.

WEDNESDAY.—8 P.M., Mr. K. Guadby: Bacteriology of War Wounds.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY.—5 P.M., Lumleian Lectures:—Dr. G. A. Sutherland: Modern Aspects of Heart Disease. (Lecture III.)

THURSDAY.—5 P.M., Goultstonian Lectures:—Dr. C. H. Miller: Parathyroid Infections. (Lecture I.)

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Hall of the Institute, 37, Russell-square, W.C.

Courses of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY.—4 P.M., Lecture X:—Prof. Sir Thomas Oliver; The Hygiene in Operation in War Time. Mrs. B. S. Chesser, M.B., Miss R. E. Squire, Miss A. M. Anderson, and Mr. G. H. Roberts have promised to take part in the discussion.

## EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

We cannot undertake to return MSS. not used.  
Offices: 423, STRAND, LONDON, W.C. 2.

## MANAGER'S NOTICES.

## ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8d. The rates of subscription remain as revised in October.

## TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 4.

## METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, March 14th, 1917.

Date.	Rain-fall.	Solar Radio in Vacuum.	Maximum Temp. Shade.	Min. Temp.	Wet Bulb.	Dry Bulb.	Remarks.
Mar. 8	...	63	35	25	Fzn.	26	Fine
" 9	...	62	39	26	32	31	Overcast
" 10	0.03	56	47	31	37	37	Overcast
" 11	0.05	56	51	37	46	47	Overcast

" 13	0.03	64	48	35	37	37	Overcast
" 14	0.14	76	47	37	43	44	Raining

Other information which we have been accustomed to give in these "Readings" is withheld for the period of the war.

The following journals, magazines, &c. have been received:—Quarterly Journal of Microscopical Science, Malattie del Cuore, Nordiskt Medicinskt Arkiv, Midland Medical Journal, Medical Review, American Journal of Public Health, Therapeutic Gazette, Revue de Chirurgie, Journal of Nervous and Mental Disease, Archives of Internal Medicine, &c.

## Communications, Letters, &amp;c., have been received from—

- A.—Messrs. Adlard and Son, and West and Newman, Lond.; Messrs. Allen and Hanbury, Lond.; Messrs. Armour and Co., Lond.; Capt. J. E. Adams, R.A.M.C.T.; Dr. Marion B. Andrews, Belfast; Messrs. Arnold and Sons, Lond.; Association of Science, Lond.; Sec. of: Arnhemsche Import Co., Arnhem.
- B.—Mr. W. Bryce, Edinburgh; British Organotherapy Co., Lond.; Mr. A. G. Berry, Lond.; Messrs. W. H. Bailey and Son, Lond.; Bolton Guardians, Clerk to the; Mr. J. F. Briscoe, Southampton; Messrs. Burroughs Wellcome and Co., Lond.; Bury and District Joint Hospital Board, Clerk to the; Surg. S. L. Baker, R.N.; British Burns Motor Lorries, Lond.; General Manager of: Birkenhead Guardians, Clerk to the; Mr. P. J. Byrne, Clonmel; Mr. J. L. Boone, Nashville, Tennessee; Mr. J. A. Byrne, Woodford; Dr. W. Langdon Brown, Lond.; British and Foreign Sailors' Society, Lond.; Mr. G. W. Baker, Leicester; Surg.-Gen. Sir David Bruce, A.M.S., C.B.
- C.—Dr. E. M. Clarke, Truro; Mr. H. A. Collins, Croydon; Dr. A. K. Chalmers, Glasgow; Mr. C. H. Cummins, Lond.; Dr. W. H. L. Copeland, Lond.; Dr. J. W. Cropper, Lond.; Mr. J. F. Colyer, Lond.
- D.—Dr. J. Donnelly, Gambaga; Drapers' Record, Lond.; Dr. F. V. Davison, Minas de Corrales; David Lewis Northern Hospital, Liverpool, Sec. Supt. of: Denver Chemical Manufacturing Co., Lond.; Miss J. H. Dewar, Lond.; Dr. V. Dickinson, Lond.; Lieut.-Col. L. S. Dudgeon, R.A.M.C.; Messrs. Duncan, Flockhart, and Co., Edinburgh.
- E.—East Suffolk and Ipswich Hospital, Ipswich, Sec. of; Lieut.-Col. T. R. Elliott, R.A.M.C.; Dr. J. Byre, Lond.
- F.—Capt. S. Fenwick, R.A.M.C.; Dr. W. M. Fletcher, Lond.; Factories, Chief Inspector of, Lond.; Finnish Booksellers, Ltd., Singers; Dr. F. Fox, Lond.; G.—Dr. C. D. Green, Romford; Capt. A. R. Green, R.A.M.C.; Mr. A. Garrow, Elgin; Grimsby County Borough, Town Clerk of; Mr. H. Grattan, Lond.; Capt. R. L. Gamlen, I.M.S. (ret'd.); Mr. E. W. H. Groves, Clevedon; Mr. H. J. Gauvain, Alton; H.—Dr. T. B. Harwood, Lond.; Capt. W. O. Halpin, R.A.M.C.; Major R. J. D. Hall, R.A.M.C.; Mr. F. W. Holland, Lond.; Dr. F. Hernaman-Johnson, Lond.; Holborn Surgical Instrument Co., Lond.; Dr. C. W. Hutt, Brighton; Messrs. W. and R. Holmes, Glasgow; Dr. N. B. Harman, Lond.; Messrs. A. Heywood and Son, Manchester; Dr. R. C. Holt, Manchester; Prof. M. Hartog, Cork; Mr. A. F. Hills, Penshurst.
- I.—Messrs. Isaacs and Co., Lond.
- J.—Capt. D. Johnston, R.A.M.C.; Capt. W. M. M. Jackson, R.A.M.C.; Dr. A. H. Joseph, Bexhill-on-Sea; Journal of State Medicine, Lond., Editor of.
- K.—Mr. D. Kennedy, Dublin; Kent Education Committee, Maidstone, Stores Supt. of; Prof. A. Keith, Lond.; Kensington and Fulham General Hospital, Sec. of.
- L.—Capt. T. Lyon, C.A.M.C.; Mr. C. E. Little, Birmingham; Messrs. H. K. Lewis and Co., Lond.; Dr. A. Love, Greenock; Local Government Board, Lond.; Mr. F. W. Lowndes, Liverpool; Dr. S. C. Lawrence, Lond.; London Throat Hospital, Sec. of; London and Provincial Retail Newsagents Association, Sec. of; London County Council Asylum and Mental Deficiency Committee, Accounting Officer of; Dr. M. Lesleur, Paris; Dr. G. C. Low, Lond.; Mrs. Langmead, Lond.; Messrs. Leslier, Lond.
- M.—Dr. N. M. Maclehole, Lond.; Messrs. Chas. Moore and Co., Lynn; Maltine Manufacturing Co., Lond.; Ministry of Interior (Lunacy Division), Atascia, Director of; Dr. R. Morton, Lond.; Mr. J. Y. W. MacAlister, Lond.; Dr. G. R. Murray, Manchester; Mrs. H. Macleod, Manchester; Clerical, &c., Association; Messrs. C. Mitchell and Co., Lond.; Mr. W. Martindale, Lond.; Messrs. Mater and Crowther, Lond.; Mr. W. E. Mayne, Belfast; Mr. A. E. Morison, Sunderland; Miss M. Milne, Aberdeen; Dr. I. Moore, Lond.; Medical Women's Federation, Lond., Hon. Sec. pro tem. of; Capt. J. McDonnell.
- N.—Mr. P. Newell, Margate; Mrs. Gladys Natrass, Jarrow-on-Tyne; National Council for Combating Venereal Diseases, Lond.; Mr. M. Nijhoff, The Hague; Newcastle upon-Tyne Education Committee, Director of; National Anti-Vaccination League, Lond., Sec. of; Newspaper Society, Lond., Sec. of; News vendre Benevolent and Provident Institution, Lond., Sec. of.
- O.—Dr. W. J. O'Donovan, Lond.; Oldham Royal Infirmary, Supt. of; Dr. A. Oudendaal, Utrecht; Sir William Osler, Bart., Oxf.ri.
- P.—Mr. H. O. Plirkington, Preston; Lieut. D. S. Pracy, R.A.M.C.; Messrs. F. J. Parsons, Hastings; Dr. A. G. Phear, Lond.; Dr. P. Pope, Lond.
- Q.—Queen Charlotte's Lying-in Hospital, Lond., Sec. of.
- R.—Royal Academy of Medicine in Ireland, Dublin; Royal Institute of Painters in Water Colours; Dr. R. R. Rentoul, Liverpool; Royal Faculty of Physicians and Surgeons, Glasgow; Messrs. Vincent Roberts and Co., Leeds; Royal Sanitary Institute, Lond.; Royal Society of Arts, Lond.; Royal Hampshire County Hospital, Winchester, Sec. of; Royal Waterloo Hospital for Children and Women, Hon. Treas. of; Miss Reading, Grantham;
- Royal Cornwall Infirmary, Truro, Sec. of; Royal Albert Hospital, Devonport, House Steward of; Royal Statistical Society, Lond.; Royal Institute of Public Health, Lond.; Royal Society, Lond.; Royal Society of Medicine, Section of Obstetrics and Gynaecology, Lond.; Mr. T. Rooney, Nairn; Royal Society of Medicine, Editor of the Proceedings of.
- S.—Capt. A. G. Shera, R.A.M.C.; Dr. W. J. B. Sumpter, Sheringham; Dr. B. I. Spriggs, Banff; Messrs. Squire and Sons, Lond.; Capt. R. M. Stewart, R.A.M.C.; Saltford Royal Hospital, Sec. of; Messrs. W. H. Smith and Son, Lond.; Dr. J. van Schalkwijk, Standerton; Sunderland Royal Infirmary, Sec. of; Messrs. Saward, Baker, and Co., Lond.; Surg. J. Shaw, R.N.V.R.; Col. A. D. Sharp, C.M.G.; Messrs. James Smith, Lond.; Mr. B. F. Slade, Lond.; Society of Public Analysts, Lond., Joint Hon. Sec. of.
- T.—Dr. D. D. Tindal, Lond.; Capt. F. J. Tee, C.A.M.C.; Dr. L. M. G. de la Torre, Lima; Taunton, Sec. of.
- U.—Under-Secretary of State, Home Office, Lond.
- V.—Verkehrsverein Davos, Davos Platz; Mr. Voncken.
- W.—Dr. N. Walker, Edinburgh; Dr. E. W. A. Walker, Oxford; Wiltshire County Council, Trowbridge, County School Medical Officer of; Messrs. A. J. Wright, Lond.; Messrs. Willows, Francis, Butler, and Thompson; Messrs. W. Wood and Co., New York; Wolverhampton and Staffordshire General Hospital, Wolverhampton, House Governor of; Walsall and District Hospital, Sec. of; Messrs. Willing and Co., Lond.; Mr. C. L. H. Wallace, Lond.; Mr. J. W. T. Walker, Lond.; W. H. H.; Major G. W. Watson, R.A.M.C. (T.); Dr. H. Woods, Lond.; Dr. F. J. Wethered, Lond.
- Letters, each with enclosure, are also acknowledged from—
- A.—A. Y. G.; A. G. B.; A. G.; A. M.; Anglo-French Drug Co., Lond.;
- B.—Mr. E. G. F. Barnes, Dublin; Surg. H. O. Broadhurst, R.N.; Dr. J. Biernacki, Lond.; Messrs. Butterworth and Co., Lond.; Mr. C. Boulangé, Paris; Brentford Guardians, Clerk to the; Lieut. N. Brady, R.A.M.C.; Mr. P. L. Booth, Walney Island; Birmingham Education Committee, Treas. to the; Bradford Childrens' Hospital, Sec. of; Messrs. Bailey and Son, Lond.
- C.—Surg. H. Carlill, R.N.; Capt. M. M. Cruickshank, R.A.M.C.; Carlow District Lunatic Asylum, Medical Supt. of; Clandon Park Hospital, Guildford, Sec. of.
- D.—Devonshire Hospital, Buxton, Sec. of; Doctor, Southsea; Lieut.-Col. A. M. Davies, R.A.M.C.; Mr. W. Dowse, Birmingham; Capt. J. D. Dyson, R.A.M.C.; David Lewis Colony, Manchester, Sec. of; Dorset County Council, Dorchester, Clerk to the; D. A. H.
- E.—Dr. V. J. Elwell, Waterloo; Messrs. Elders and Fyffes, Lond.; Messrs. E. Evans and Sons, Shanghai.
- F.—Col. A. Fullerton, A.M.S.; Messrs. Fannin and Co., Dublin; Ford Motor Co., Lond.
- G.—Surg. P. C. Gibson, R.N.; Capt. N. F. Graham, R.A.M.C.; Capt. G. W. Goodhart, R.A.M.C.; Major J. H. P. Graham, R.A.M.C.; Capt. P. W. Green, R.A.M.C.; Messrs. A. H. Grantham and Co., Reading; Messrs. Godsell and Barnett Smith, Lond.; E. T.; Dr. P. E. Garrett, Earl Shilton; Capt. H. D. Gillies, R.A.M.C.; H.—Messrs. Holt and Co., Lond.; H. M. Stationery Office, Lond.; Haslemere Nursing Home, Sec. of; H. G. D.; H. M. B.; Surg. F. G. Hitch, R.N.
- H.—Lieut. A. B. Jones, R.A.M.C.; Messrs. F. Jackson and Co., Lond.; Dr. W. P. Johnstone, Marsburg; J. M. B.
- K.—Messrs. Kegan Paul, Trench, Trübner, and Co., Lond.; Dr. F. Keyt, Hong-Kong.
- L.—Mr. I. P. Llewelyn, Lond.; Sir W. Arbuthnot Lane, Bart., C.B.
- M.—Dr. G. W. Middlemiss, Settle; Dr. J. Matheson, Lond.; Dr. H. A. Moody, Lond.; M. S. R.; Mercantile Bank of India, Lond., Manager of; M. M. C.; Dr. M. Macnaughton-Jones, Lond.; Mr. A. R. MacGregor, Barnstaple; Messrs. J. Menzies and Co., Glasgow; Lieut.-Col. McLaughlin; Capt. H. B. Moyle, R.A.M.C.; Medical Research Committee, Lond., Sec. of.

## The Lumleian Lectures

ON

### MODERN ASPECTS OF HEART DISEASE.

*Delivered before the Royal College of Physicians of London*BY G. A. SUTHERLAND, M.D. EDIN.,  
F.R.C.P. LOND.,PHYSICIAN TO THE HAMPSTEAD AND NORTH-WEST LONDON HOSPITAL;  
PHYSICIAN TO THE PADDINGTON GREEN CHILDREN'S HOSPITAL.

#### LECTURE II.<sup>1</sup>

*Delivered on March 15th.*

##### DISTURBANCE OF CARDIAC RATE.

MR. PRESIDENT AND GENTLEMEN.—The second great disorder of the heart is characterised by a disturbance of the rate, which in the vast majority of cases means an acceleration, and in the minority a retardation, of rate. An increase of the heart's rate, as compared with the normal standard of adult life, may be found under various conditions, both physiological and pathological. Thus in infancy and childhood the heart beats more rapidly, and may be presumed to do so in order to meet the demands of the growing organism. In many forms of general disease an increase in the cardiac rate is part of the general disturbance, just as a rise in temperature is. The increase is not probably of much importance in itself and does not, as a rule, lead to any special symptoms.

##### *Acceleration of Cardiac Action.*

In connexion with actual disease of the heart, writers in the past have noted the frequent occurrence of a rapid cardiac action, and they have speculated widely as to the causes of this increase. As a rule the symptom, especially if progressive, has been ascribed to increasing feebleness of the myocardium and cardiac failure. The writers do not seem to have considered very fully what the results of a persistently rapid action are on a previously damaged heart. Yet this question is one of great practical importance in connexion with prognosis and treatment. The old terms "failure of compensation" and "broken compensation" conveyed no information of any value because the actual process at work was unknown. These descriptive terms are now known to apply to conditions of cardiac failure brought about in many cases by an increase of cardiac rate, or, to be more precise, by the weakening effect which the rapid rate has on the efficiency of the left ventricle.

It may be allowed that there is a certain range of alteration in the cardiac rate, above and below the normal, which in all probability has no important effect on the heart and leads to no symptoms. As regards an increase, if we take 75 beats per minute as the normal, an increase up to 100—that is, of 25 beats—will not probably be productive of any definite effect on a healthy heart. Similarly, a reduction of the rate to 50—that is, of 25 beats, will not of itself affect the efficiency of the heart. It is outside these limits that we find symptoms beginning to appear which are to be traced to the heart-rate. It is not only from the symptoms that we can infer that the rate is affecting the heart's efficiency; there are also definite changes in the heart itself, for example, dilatation, and evidences of a deficient circulation, for example, congestion of the liver, which may follow as a direct result of an excessively rapid action of the heart.

If we take 100 beats per minute as our limit for cardiac efficiency we shall find that every increase of 10 beats may make a difference in the efficiency. Such an increase certainly makes a difference in the strain thrown upon the heart, so that we may express the increase as being a 10 per cent., 20 per cent., or 50 per cent. added strain to the heart, according to the number of heart beats above 100 added per minute. Although the ventricular contractions are weaker as compared with those of the normal or slower rate, no perceptible changes may follow at first. Working at an increased rate the ventricle eventually suffers because of the loss or diminution of its normal resting time (diastole) when fresh energy is built up. It may be that for a time a doubling

of the ventricular rate allows of the circulation being maintained at its former level, or even in some ways of being improved, but the continuance of such a rate will eventually tell on the ventricular power. If we adopt the terms "rest power" and "reserve power" as applied to the heart, it will naturally be the reserve power which is diminished first.

It will probably be found that a continuous rate of 120, 130, or 140 will always tend to affect the ventricular action eventually. An 80 per cent. increase (rate of 180) will be sooner productive of serious results. These will arise even in hearts which have been previously healthy, but naturally they will be manifested sooner in hearts which are diseased. There are certain factors which have to be taken into account in estimating how a diseased heart will be affected by a marked increase of rate—that is, above the standard of 100 beats per minute. (1) The age of the patient. In the young an increase of rate is not so pathological or so productive of injurious effect as in adult life and old age. (2) The state of the myocardium of the left ventricle. A healthy myocardium will "carry on" successfully, when a diseased myocardium would show signs of stress. (3) The amount of strain already thrown on the ventricle from associated disease in other parts—for example, the presence of valvular lesions. (4) An associated irregularity of rhythm. The diastolic filling of the ventricle, already defective by reason of the arrhythmia, may be seriously interfered with by the shortening of the diastole. The effect of the cardiac irregularity may thus be much enhanced by an increase in the rate. (5) The suddenness of onset of a great increase of rate may disturb the ventricular action much more than if the process had been slow and progressive. This is well shown in some forms of tachycardia, when the heart has no time to accommodate itself to the excessively rapid action which sets in abruptly.

During the course of a general infection (rheumatic fever) or during active carditis an increase of cardiac rate may be regarded as a normal reaction. It does not, as a rule, demand any special treatment, because it is usually moderate in degree and a temporary disturbance. The class of case in which a rapid rate may be said to be injurious is that in which, in the absence of any general cause or local cardiac inflammation, there appears to be a permanently irritable or excitable focus in the heart. From this focus start numerous impulses which, while causing frequent contractions in the auricles, unimportant in character, may also cause an excessive rate of ventricular contractions. Under these conditions the increase of rate does not cease while the patient is asleep, although it may be less pronounced, and it may be considerably augmented by excitement or by physical exertion. The reserve power of the heart is certainly diminished in all such cases, and according to the degree and persistence of the increased rate the rest power may be encroached on. This subject will be further referred to when we deal with the question of therapeutics.

##### *Retardation of Cardiac Action.*

A slow rate of the heart, slower, that is, than 40 beats per minute, may also have, if prolonged, an injurious effect on the circulation. The ventricle does not suffer in itself, but under certain conditions it fails to maintain a sufficient supply and pressure of blood in different organs, more especially in the cerebral centres. A total bradycardia—that is, a slowing of the heart-rate which starts at the sinus node and is continued through the heart-beat—is not usually of clinical importance. The pathological slowing, which is important, will be found dealt with and explained under the heading of "Heart-block" in the current literature. It forms a particularly illuminating chapter in the history of the successful analysis of disturbances in the cardiac rhythm and rate. Gaskell found that by clamping the junctional tissues which form a bridge between the auricles and ventricles he was able to form a barrier or block, so that only a certain number of impulses passed through. According to the amount of pressure exercised, only every second or third or fourth impulse was able to pass, and the ventricular action was slowed accordingly. This is known as partial heart-block. By raising the pressure still more he was able to form a complete barrier or block, so that no impulses at all reached the ventricle from above. This is known as complete heart-block. When this happens a latent and unsuspected action of the ventricle comes into play, as shown

<sup>1</sup> Lecture I. was published in THE LANCET of March 17th, 1917, p. 401.  
NO. 4882.

by its starting a rhythm and rate of its own, at first rather irregular, but tending soon to settle down to a regular beat at a rate much below normal. So that below the junctional tissues, in some part of the ventricular wall, there lies a centre, usually dormant, capable of impulse formation and discharge and of starting ventricular contractions.

The clinical bearing of these facts has been very thoroughly worked out by Mackenzie. He showed that in disease partial heart-block is frequently produced through lesions of the junctional tissues. The conducting bridge of the junctional tissues becomes a barrier to the impulses descending from above, and only a certain number get through at regular or irregular intervals, so that the rate and regularity of the ventricular contractions bear no fixed relation to the auricular rate and regularity. The ventricular rate is influenced by the rate at which impulses are able to pass the barrier. The clinical proof of these conditions can be demonstrated very clearly by means of graphic records. It would appear, further, that partial heart-block may result not only from damage to the junctional tissues, but from an excessive number of stimuli descending from above and exhausting the powers of conductivity of normal junctional tissues. The bridge becomes blocked from excess of traffic. This is manifested in the clinical conditions of auricular flutter and auricular fibrillation. The conducting tissues are stimulated to such an extent that they are incapable of transmitting all the impulses reaching them. The condition of partial heart-block is thus seen to be proved in experimental physiology; it is also demonstrable in various forms of cardiac disease and disturbance, and it is capable of being induced by means of drugs in the treatment of heart disease, as will be described later in dealing with digitalis therapy.

Complete heart-block is the result of organic disease affecting the junctional tissues to such an extent that no impulses reach the ventricle from above. The idio-ventricular rhythm and rate which then develop, or which may develop, are apt at first to lead to attacks of syncope because of the prolongation of some of the diastolic pauses. After a time the action becomes more regular, the rate is usually about 30, and symptoms of ventricular inefficiency may disappear. The site of origin of this rhythmic action of the ventricles is now reasonably assumed to be in some part of the auriculo-ventricular bundle in connexion with the ventricles. One thing marks it out as different from all the other abnormal rhythms which have been considered. When a new rhythm has been started from some abnormal focus we have found that the rate was always faster than normal. As the result of complete heart-block the new rate of the ventricles is always slower than the normal rate. The new rate, although slow, may allow of a sufficient number of ventricular contractions to ensure the maintenance of the circulation, at perhaps a lower level than formerly. The important point about the new rhythm is that it should be regular. If the intervals between the beats are too prolonged the pressure in the cerebral vessels falls, and unconsciousness and even convulsive movements follow. These conditions are seen clinically in the symptom-complex which is known as Stokes-Adams's disease. If the ventricular rate falls below a certain level the intervals between the beats are so prolonged that death ensues.

#### *Relation of Disturbances to Supra-ventricular Tissues.*

The disturbances in rhythm and rate which we have been considering have come to occupy a most important place in connexion with the etiology of cardiac weakness and cardiac failure. We have already stated that these disturbances tend to affect injuriously the efficient action of the left ventricle. It is interesting to note, further, that every form of disordered action of the heart, be it an irregularity of rhythm or an excessive rate, or a diminished rate, is always supra-ventricular in origin. That is to say, these disturbances arise outside of the contractile muscle of the ventricles, except, perhaps, the ventricular extra-systole. There may be other exceptions to this, but so far as is at present known they must be extremely rare. Clinically, we find that the above general statement holds good. The supra-ventricular tissues, as previously defined, are the sino-auricular node, certain parts of the auricles, the auriculo-ventricular node, and the auriculo-ventricular bundle. In health these tissues regulate the rate and rhythm which are designed to lead up to efficient ventricular contractions. In diseased conditions of the heart disturbances in these tissues may lead, and do lead,

up to disordered and impaired ventricular action. Some forms of supra-ventricular disturbances if reproduced in their entirety in the ventricles would make efficient ventricular action impossible. Thus, if a condition of auricular fibrillation spread unchanged to the ventricles, efficient action of the latter would cease at once and a fatal termination would ensue. As a matter of fact, sudden death does occur from ventricular fibrillation, and it is now believed that sudden death under chloroform anaesthesia is due to ventricular fibrillation. By a process of blocking of certain of the impulses at the junctional tissues—partial heart-block—a diminished number of them reach the ventricles which are thus able to carry on the circulation. To express this in another way, impulse formation and impulse discharge may develop at a dangerous rate—dangerous, that is to say, if it spread to the ventricles—but the conducting tissues fail to develop the same rate of conductivity, and the ventricular action is successfully carried on.

The disturbances referred to above arise in the heart and as a result of disease of the heart. Other injurious influences arising from without may reach the heart through the nervous system and produce similar disturbances. They have first of all to pass through the defences of the supra-ventricular tissues, where they are often so modified that any threatened danger to the ventricles is removed. We may regard the vagus and the accelerator nerves as always on guard and controlling the functions of the supra-ventricular tissues for the benefit of the ventricles. So that it would appear that the ventricles are partially protected by the supra-ventricular tissues from disturbances which may arise in the heart itself or which may reach the heart from without.

#### *"Soldier's Heart."*

Amongst the varieties of disordered action of the heart the war has brought into prominent notice is one which is known as "the soldier's heart" or "the irritable heart of soldiers." It is in no sense comparable to the conditions we have been discussing and for this reason. The disordered action of the heart which occurs in heart disease is the result of definite changes in the muscular tissues of the heart, the supra-ventricular tissues more especially, which have arisen from inflammatory or degenerative lesions. The disorder is primarily cardiac in origin. On the other hand, the disorder in the case of the soldier's heart is essentially not cardiac in origin; it is the result of disturbance or disease in other parts of the system, which react on the heart and modify its action. This is shown in many ways. In the first place, we do not find any signs of organic heart disease to which the symptoms may be referred. The symptoms themselves are not such as can be definitely associated with any known form of heart disease, but they resemble closely those present in patients suffering from a "neurotic heart." Again, we find many other changes present which are not traceable to the cardiac condition, but clearly to a common cause. It is not the heart alone but the whole vascular system which is affected, and it is not affected in the way which we see as the result of heart disease. There is a loss of tone or power in the whole cardio-vascular system.

As regards the primary cause of the disturbances opinions still differ. Physical stress and strain, anxiety, sleeplessness, infective disease, preceding illness, and toxæmia have all been assigned the first place, and possibly each will be found to play a part if a sufficient number of cases are taken. Whatever the primary cause of disturbance one cannot fail to note in the patients the presence of nervous irritability and instability, that general condition which for want of a better term we call neurasthenia. It would appear likely from the symptoms in cases of "soldier's heart" that the cardiac phenomena do not proceed from the heart primarily, but from a disturbance of the power and action of the heart arising in the nervous centres which act on the heart. In an interesting analysis of 40 cases of "soldier's heart" John Parkinson found that in about half the cases the same disability had been present to some extent in the civil occupations pursued before the war. As he expresses it, "these men are the subjects of a cardiac disability which is unmasked by the exertion required of a soldier." This disability, whether constitutional or acquired, does not come into the category of organic heart disease. On the other hand, if certain symptoms persist—for instance, tachycardia—the effect on the heart may be as exhausting as if the tachycardia had been primarily cardiac in origin.

## DILATATION OF THE HEART.

Dilatation of the heart, of one or more of its chambers, has long been recognised amongst the changes associated with valvular disease. The view taken was that dilatation was a sign of weakness, a sign that the heart was yielding to some stress or strain more than it could effectively deal with. Another form of dilatation recognised was that in which the condition developed suddenly, usually in a heart previously diseased, and was accompanied by an increase in the old symptoms or the development of fresh ones. This was called acute dilatation of the heart, and the patient was subjected to treatment for the reduction of the dilatation. As we read the clinical reports of such cases it seems clear that the sudden onset of dilatation was usually the result of some strain thrown on the heart, and was associated with the presence in the heart of a disordered action of rate or rhythm, or both. We must not, therefore, assume off-hand that the dilatation was the primary condition, or that it was due to some essential weakness of the myocardium.

*Results of Experimental Research.*

The whole subject of dilatation, which in its most important aspect means dilatation of the left ventricle, is admittedly one of great difficulty. It deals with the qualities of tonicity, contractility, and relaxation in the cardiac muscular tissues. On the physiological side Starling and his co-workers have recently promulgated some new views on this subject.

They state that the ventricles cannot dilate unless fluid enters them. The view that there is such a condition as muscular dilatation, leading to a filling of the ventricles by suction, does not seem to receive physiological support. If blood does not enter the heart the ventricles do not dilate at all during diastole, and may become smaller with each systole until they are empty. This is not the result of increased tonicity of the heart, but is purely a mechanical result of absent or deficient venous inflow.

Comparing the cardiac muscle to an ordinary skeletal muscle, Starling says the extending load is represented by the diastolic intracardiac pressure and is dependent on the inflow; the load against which the cardiac muscle has to contract is represented by the pressure in the aorta. In his experiments he found that it was length of cardiac muscle rather than tension which determined the energy of contraction, so that there existed a direct proportion between the diastolic volume of the heart—that is, the length of its muscle fibres—and the energy set free in the following systole. This would seem to mean that to bring out the maximum capacity of a healthy heart a moderate dilatation is advantageous. Fatigue is shown by the fact that, starting at a given length, the change from the relaxed to the contracted state is attended with a smaller production of tension than was the case when the muscle was fresh. This means that a tired heart must dilate in order to carry on the same work as the fresh heart, and this is what Starling found actually occurred. If the condition is relieved, say by increasing the supply of oxygen to the heart or by diminishing the load, and the muscular tissue of the heart is given an opportunity to recover, the heart may once more return to its normal size, the evolution of energy per unit length of the muscle fibre at each contraction becoming the same as before.

This is his understanding of the word tonus or tone as applied to cardiac muscle. The term is properly employed as synonymous with physiological condition or fitness of the muscle fibre, and its measure is the energy set free per unit length of muscle fibre at each contraction of the heart. A good heart—that is, one with a good tone—will carry on a large circulation against a high arterial pressure and nearly empty itself at each contraction; while a heart with a defective tone, as is the case when it is tired, can carry on the same circulation, but only when its fibres at the beginning of contraction are much longer, that is when the heart is dilated. In the latter case the output of blood will be the same as in the former, but both the systolic and the diastolic volumes of the heart will be increased. When this dilatation proceeds to such an extent that the tension of the muscle fibres becomes increasingly inadequate in producing rise of intra-cardiac pressure, the fatigue of the heart passes on to cardiac failure.

*Clinical Support of Experimental Results.*

Turning to the clinical side we find a good deal of support for Starling's experimental results. In the case of

healthy children there is a marked instability of all the cardiac functions, and dilatation of the heart is by no means uncommon. The fluctuations in size of the heart at this age are such as to suggest strongly that there is a self-regulating influence at work, seated in the heart, which adjusts the size of the heart to the varying calls on its powers. In the case of severe athletic exercises, such as running a race, we find that the heart becomes temporarily dilated, apparently in all its chambers. Here, again, we may assume that the dilatation is the result of the strain thrown on the heart, and is called for in order to meet the difficulties of the circulation. When an attack of paroxysmal tachycardia sets in, the patient and his heart having been previously healthy, there is not necessarily any dilatation of the heart or any noticeable change except in rate. But when symptoms of fatigue of the heart appear, breathlessness, &c., dilatation usually comes on, and this may well be an effort to render the ventricular contractions more effective. When the attack of tachycardia ceases the cardiac dilatation usually subsides rapidly. The onset of auricular fibrillation is often characterised by great distress in the breathing and a marked degree of cardiac dilatation. Usually such dilatation has been ascribed to weakness of the wall of the left ventricle; but, on the other hand, it may simply be an attempt on the part of the heart to overcome the fresh difficulties of the circulation.

The point of view that dilatation is not necessarily an indication of weakness of the cardiac muscle, and may be one of the means by which the cardiac muscle meets a disturbance or difficulty in connexion with the circulation, does not imply that it meets all difficulties in this way or that cardiac failure cannot occur without dilatation. As a matter of fact, we know that the contrary holds true. Clinical research may well be directed into determining more exactly what are the underlying conditions which give rise to dilatation. Possibly it may be that in cases of extensive degeneration the cardiac muscle has lost the power of dilating. Starling has emphasised the fact that the question of dilatation is closely associated with the venous inflow of the heart, the quantity and the pressure of the flow. He says that the output of the heart is equal to, and determined by, the amount of blood flowing into the heart, and may be increased or diminished within very wide limits according to the inflow. With a minimal inflow the venous pressure on the two sides of the heart may be zero, and with increasing inflow rises at first only slightly as long as the amount of blood flowing in is not more than sufficient to exert a minimal distension on the relaxing ventricles. With further increase in the inflow the venous pressure may be positive during diastole, causing an active distension of the heart, and an increase in the rate of filling. The greater the arterial resistance the higher will be the venous pressure, for any given inflow. It seems probable from these conclusions that while certain disturbances, such as excessive rate or a disordered rhythm of the heart, may tend to induce dilatation, the question of the venous inflow and pressure has also an important bearing in determining the amount of dilatation.

## SYMPTOMS.

The discovery of physical signs of heart disturbance or disease is always satisfactory from a diagnostic point of view. The presence of a cardiac murmur or irregularity does not, however, convey much information as to the functional efficiency of the heart. This question is decided chiefly by the symptoms which are complained of by the patient, or which are brought out by testing the response of the heart to various forms of physical exertion.

Symptoms are the signals of distress sent out by the heart when its efficiency has become impaired. In cases of chronic heart disease the physical signs may persist unchanged for 10 or 20 years, and the first indications of weakening of the cardiac force are to be found in the symptoms. We have therefore come to regard symptoms as the most reliable evidence of impaired action of the heart and circulation. Amongst the chief of these symptoms may be mentioned breathlessness, pain, palpitation, languor, giddiness, faintness, and fainting.

A symptom may be unrecognised by the patient. For instance, breathlessness, quite apparent to outsiders, may have come on so gradually as not to have attracted the patient's attention. In other cases the symptom—for example, pain—may be not only recognised, but very much

emphasised and exaggerated by the patient. The sensitiveness of the individual varies to an enormous extent, so that while in some cases we hear of few symptoms in others we are met with a multiplicity of them which is embarrassing. In the one case more leading and particular questions are to be asked, and in the other the different symptoms are to be more minutely examined into. It has also to be recognised that many of the symptoms associated with organic disease are reproduced with marvellous accuracy in functional disturbances of the nervous system. So that in dealing with symptoms, and in order to estimate them at their proper value, the important thing is to establish a clear correlation between the physical signs of heart disease and the symptoms complained of or elicited by testing the response of the heart to effort. Further, as the symptoms of heart weakness are not distinctive, one has to exclude other possible causes than the heart. Such symptoms as breathlessness, praecordial pain, and palpitation may come from disturbances in various organs and regions of the body. An enlarged liver and fainting attacks are not necessarily due to heart disease. Shortness of breath and a cardiac murmur or irregularity may be present without organic heart disease. Chronic renal disease and arterio-sclerosis may lead to many symptoms not unlike those of heart disease. So that while in many cases the establishment of a definite correlation between the symptoms and the signs of cardiac disease may be easy, in others care may be necessary lest we assume too readily from the presence of symptoms the existence of heart disease as the cause. Patients are especially liable to fall into this error and to come with a ready-made diagnosis of "something wrong with the heart."

Symptoms are a measure of the difficulty with which the left ventricle is meeting some strain thrown on its action. Fatigue of the heart may be shown by symptoms only after some unusual exertion has been made which, however, the patient had previously been able to make without discomfort. A further stage—weakness of the heart—is shown when the patient has increasing difficulty in making any exertion without the onset of symptoms. In Mackenzie's language this implies a diminution in the "reserve power of the heart." A further stage—failure of the heart—is reached when symptoms are present even when the patient is resting in bed or on a chair. In Mackenzie's language this means a diminution of the "rest power of the heart." In connexion with heart disease, fatigue, weakness, and failure, as defined above and as shown by the symptoms, may be regarded as milestones indicating the progressive impairment of ventricular action. Whatever the physical signs in the heart may be, a sound prognosis must take into account the importance of the symptoms, and successful treatment will be shown by the diminution or cessation of the symptoms.

#### *Relative Importance of Signs and Symptoms at Different Ages.*

We expect and usually find symptoms present at all ages when the patient is the subject of acute heart disease (myocarditis, endocarditis, pericarditis), or of a sudden and severe disturbance of rhythm such as auricular fibrillation. In the chronic forms of heart disease we find a marked difference in the relative importance of symptoms and physical signs at different ages in estimating the question of cardiac impairment.

In the young, say up to the age of 15 years, heart disease is usually part of the rheumatic infection. At this period of life the re-operative powers of the heart after an acute attack are little short of marvellous, and the symptoms manifested or complained of are often extremely slight or absent altogether. Yet the heart may have been permanently damaged. At this age, therefore, the physical signs of disease are much more important than the symptoms in forming an estimate as to how far the cardiac efficiency has been or will be impaired. It is on the physical signs that the prognosis is to be based, so far as a prognosis can be given during the years when rheumatic reinfection is so apt to occur. Symptoms, the result of disease in early life, may not assume any importance until maturity is reached or even later. Possibly the physical signs of disease may not have altered much since childhood, but impairment of the functional efficiency of the left ventricle will first of all be indicated by symptoms when the physical stress of life has begun to tell on the previously damaged heart.

From middle life on through old age there is another large class of case met with—namely, those with degenerative changes in the musculature of the heart. Here the physical signs of heart disease may be slight or absent, but the symptoms are often clearly indicative of weakness in the action of the left ventricle. The extent of the weakness can be roughly estimated by the response which the individual makes to effort, long before confirmatory evidence is obtained in the form of oedema, &c.

#### CARDIAC THERAPEUTICS.

In acute inflammatory disease of the heart it is generally agreed that the field of direct cardiac therapeutics is extremely limited. We employ measures to allay or remove any infective disease in the system, such as rheumatic infection, and we adopt those measures which experience has shown useful in the case of fevers generally. We do not possess any direct means of checking disturbed action or strengthening cardiac action when the heart is in a state of inflammation, acute or subacute. This period is short-lived compared with that which follows, in which the effects are shown in the form of chronic heart disease. The time at which the treatment of chronic heart disease begins and the form which it takes seem to vary considerably with the individual therapist. In some cases whenever a cardiac murmur is discovered digitalis is given. In others, when a valvular lesion is diagnosed from the murmur, digitalis is given. In others, when some change in the heart is diagnosed as the result of a valvular lesion, digitalis is given. In others again, while valvular lesions and cardiac changes may have been recognised, treatment is deferred until "compensation has broken down." These statements are not based on the teaching or text-books of the day, but on the experience gained in professional intercourse. It is not necessary to consider any treatment which is based merely on a cardiac murmur or a valvular lesion, but that based on failure of compensation calls for comment.

#### *Nature of Compensation and Compensatory Changes.*

The so-called compensatory changes are the result of efforts which the heart has made to overcome some mechanical interference with its efficient action. In its simplest form it is seen in the dilatation and hypertrophy of the wall of some chamber in order to overcome the effect of an obstruction in front, for instance, the right ventricle in mitral stenosis. We may compare this with the dilatation and hypertrophy of the stomach wall in pyloric stenosis. The compensatory change is more complicated in the case of aortic regurgitation with mitral regurgitation when the left ventricle has to compensate for a great loss of its systolic power by a double valvular leakage. In the case of adherent pericardium, when some part of the heart is fixed to the chest wall, the compensatory changes may be of a most complicated kind because of the tying down of the heart.

In all of these cases great changes may take place in the size of the heart, and they are evidently purposive and directed solely to the carrying on of the circulation. How are they brought about? It would appear that the automatic powers of the heart are solely responsible for these changes. For they are manifested in cases in which no treatment has been adopted, and they are seen more especially in youth when the natural recuperative and adaptive powers of the heart are much greater than in later life. In the case of a very large and hypertrophied heart we may assume that the unaided powers of nature have produced the condition, and that the enlargement is compensatory in character. There is no known method of producing such a result by drugs or other treatment, and it is very doubtful whether we shall ever be able to improve on it.

#### *Condition when Compensation has Broken Down.*

Such would appear to be the nature of compensation and compensatory changes. What is the condition when compensation has broken down? The term "failure of compensation" was applied in cases where there was a more or less sudden breakdown of the heart, with marked subjective symptoms of distress and usually with well-defined physical changes in the heart. The old view was that the heart had given out. Sometimes it was described as "right-sided failure" and sometimes as "left-sided failure," according to the predominance of certain signs. The aim of hopeful therapeutics was "to increase the tone of the heart muscle," or "to strengthen the cardiac action," or "to improve the

contractile power of the heart," as it was variously expressed. Now, if we are not able to add one muscular fibre to the heart or to improve the contractile power of the heart in order to prevent the "failure of compensation" it does not appear to be likely that we shall be able to do so when failure has set in. Yet this was what was usually attempted in cases of "loss of compensation" and what many claim still that they can do by means of digitalis.

There may be attacks of cardiac weakness induced by over-exertion or illness, but they are temporary and relieved by rest and do not fall within the category of failure of compensation. There may also be failure of the power of the left ventricle to carry on the circulation, a primary loss of contractile power from exhaustion, in which case the end is not usually far off, and treatment is of little avail. But in the vast majority of cases of "failure of compensation" with symptoms there is a new factor present which is of great importance. That factor is the development of a new and abnormal rhythm in the heart, which has interfered with the cardiac action to such an extent that a "failure of compensation" has been diagnosed. The abnormal rhythm is, as a rule, accompanied by a great increase in the ventricular rate, and this adds to the impairment of the cardiac efficiency.

Now the importance of these two, an abnormal rhythm and a rapid action of the heart, would appear to lie in this, that they react so injuriously on the ventricular contractions as to produce the signs and symptoms on which a diagnosis of "failure of compensation" has been based. One might say that there has been a disturbance of the compensatory action of the heart, in the sense that this action is weakened from the presence of a new rhythm or from tachycardia. But to say that "compensation is lost" is to say that all is lost, for the carrying on of the circulation has been dependent on the compensatory changes, and we cannot influence them directly. As a matter of fact, in cases coming under this description we know that if the disturbing factors are removed or checked by treatment the compensatory changes will be found unimpaired and ready to carry on the circulation efficiently. Successful treatment will depend on the recognition of the exact form of disturbance which has upset compensation and on the application of the above facts in the employment of our chief drug in heart disease—namely, digitalis.

#### *Direct or Indirect Action of Digitalis?*

In considering the action of digitalis a clear distinction must be drawn between its direct and indirect action. The fact that it has a special and direct action on the cardiac action is universally accepted, and the method of this action will be discussed later on. It has also been maintained by many that digitalis has a direct action on the kidneys, on the arterioles, and on the blood pressure, while others assert that this is only an indirect action due to and dependent on the increase in the cardiac efficiency. The former view is probably based chiefly on experimental work on animals, the deductions from which have been applied, without clinical observation, to the human subject under conditions of cardiac failure. Experience has shown that conclusions of this nature are extremely unreliable.

The view that digitalis has only an indirect action on the kidneys is now strongly supported by pharmacologists and physicians. Cushny states that the diuresis "appears to arise not from a direct action on the secretory mechanism, but only indirectly through the changes in the circulation; the kidney shares in the general acceleration of the blood and functions more vigorously." The change in the renal activity under digitalis is not due to any local vascular action but to the augmented activity of the heart, which improves the nutrition and promotes the activity of the kidney. At the same time, the increased power of the heart quickens the circulation in the lymphatic system, dropsical fluids are reabsorbed into the blood-vessels, and are excreted by the kidney.

These views of Cushny appear to fit in very well with the clinical results which we obtain from digitalis. We can see similar circulatory changes produced in other organs of the body—for example, the liver. In heart failure the liver is often swollen and engorged with blood, the patient is jaundiced, and bile appears in the urine. The condition is assumed to be one of hepatic venous congestion with deficient excretion of bile. When the cardiac efficiency has been restored by means of digitalis the hepatic con-

gestion and swelling subside and bile is again freely excreted. We do not say that in such cases digitalis acts as a chalagogue, or assume that it has any direct action on the liver, although its action here is probably exactly the same as on the kidneys. Similarly, when the clouded brain is cleared, the edematous lungs are relieved, and the stomach and intestines are freed from their congestion, we do not consider that digitalis has a special action on these tissues.

Another fact to be remembered is that digitalis has not been found to be efficient as a diuretic save in cases of cardiac dropsy. Its employment for diuretic purposes may be said to be confined to cases of cardiac disease with dropsy. Those who accept the view that digitalis is a diuretic because of its direct action on the kidneys must be prepared to show that there is some special condition present in the kidneys peculiar to cardiac dropsy. No such condition is known, and, in fact, in many cases when the congestion of the kidneys has been relieved the kidneys are found to be perfectly healthy.

#### *Diuretic Action of Digitalis Alone and Combined with Theocine.*

In many cases we can say with confidence that the dropsy will disappear when digitalis has restored efficient cardiac action. We do not understand fully the underlying causes of oliguria in cardiac cases, any more than we know the exact mechanism of cardiac oedema, but we can observe sequences in the treatment of dropsy. In my experience the diuretic action under digitalis is often of a sluice-gate character, in which some holding back influence has been removed and the excess of fluid is poured out through the kidneys. The time at which this is secured is more or less synchronous with the recovery of ventricular efficiency, and in the most typical cases this comes soon after the cardiac rate has been lowered. If, on the other hand, the cardiac rate has been and continues normal, and no appreciable change in the cardiac efficiency takes place under digitalis, we do not usually find much evidence of a diuretic effect.

In some cases we do not get the expected diuretic action of digitalis, even although it may have been effective in relieving the other symptoms. Something additional seems to be required to "tip the balance" and make the kidneys act. This may be accomplished by such means as a sharp purge or dose of mercury, or by partially relieving the dropsy by Southey's tubes, or it may be brought about by some such trifling alteration as a change of posture, as Mackenzie points out. He finds that "the kidney functions, when there is dropsy, are peculiarly unstable," and this is probably the common experience.

It will also be found that the caffeine series of preparations, when used along with digitalis, are at times very effective in inducing diuresis. I cannot specify the exact underlying renal conditions which are present. It has appeared to me that the theocine-digitalis combination has proved specially suitable in cardio-renal cases—that is, when both heart and kidneys are diseased. A most efficient preparation is theocine-sodium-acetate, and the action is often very striking. Unlike that of digitalis it begins almost at once, and may start within an hour of the first dose. If no effect is manifested within 24 hours or after 40 grains it is of little use continuing the drug. Theocine appears to act most effectively in combination with digitalis and after the patient has taken a sufficient amount of digitalis to affect the heart. While digitalis alone may procure a diuretic effect theocine alone is not usually effective if the dropsy is essentially cardiac in origin. The action of theocine is no accidental one, for it can be repeated in the same case, and its effect is so prompt that the element of chance can be excluded.

The diuretic action of digitalis in cardiac dropsy can only be estimated properly when the kidneys are healthy and merely disturbed in their function from circulatory weakness. If renal disease is present other factors may come into play which cannot at present be estimated. The diuretic effect under digitalis is not usually started until after 48 hours from the commencement of treatment. This of itself is suggestive of an indirect rather than a direct diuretic action. Mackenzie has noted in some cases the onset of diuresis within 48 hours of the administration of digitalis and before any effect on the heart was perceptible. He thinks "it is probable that the beneficial effect produced by the drug is

due to its diuretic effect rather than to its action on the heart." We have already considered some difficulties in the way of accepting this view. In several of his cases chronic renal disease was present so that they were not suitable for deciding the question at issue. Accepting his facts as to these exceptional cases, we may offer another explanation than the one he has given. Digitalis, amongst its other effects, has an irritant action on certain tissues which is more pronounced in some people than in others. Thus diarrhoea may follow quickly from the use of quite moderate doses. Cushing points out that digitalis may act as an irritant to the renal epithelium, as the appearance of blood and albumin in the urine of animals after large doses of digitalis shows. Mackenzie usually begins treatment with full therapeutic doses of digitalis, and the irritant action of the drug may have told on the kidneys before the cardiac action has had time to take effect. Such an action would not bring digitalis into the category of diuretic drugs, although it might explain the early diuretic effect in some cases of cardiac dropsy.

#### *Action of Digitalis on Arterioles and Blood Pressure.*

It was formerly held by pharmacologists, as the result of experimental work, that digitalis contracted the arterioles in animals and raised the blood pressure. These statements were accepted by clinicians as applicable to the employment of therapeutic doses of digitalis in man for heart disease. Further, warnings were given that owing to this action care must be taken in certain forms of heart disease lest it should react injuriously on a weakened heart. More recent pharmacological investigations have shown that digitalis has no such action on the blood pressure, which is affected only by the increased efficiency of the cardiac contractions. Cushing points out that there is a balanced action between the increased force of the heart's contractions and the tone of the vasoconstrictor system. An augmented efficiency in cardiac contraction would lead to a rise in blood pressure provided that the blood vessels remained unchanged in calibre. But as the output of the heart increases the vessels relax in proportion and the flow of blood is accelerated. This compensatory action arises in the vasoconstrictor centre, and as long as it persists the blood pressure does not rise.

Cushing's conclusions have been supported clinically by the investigations of Mackenzie and his pupils. In what is perhaps the most important form of disease in this connexion—namely, auricular fibrillation—they found that no estimate of the blood pressure could be made, as it was constantly changing. In cases with a regular rhythm they could detect no appreciable effect upon the blood pressure. Digitalis and the blood pressure is still a subject of interest to senior students because of its value for examination purposes, but after the examination is passed the student may dismiss the subject and rest assured that its value to him from the clinical and therapeutic point of view is negligible.

## "SOLDIER'S HEART."<sup>1</sup>

BY ADOLPHE ABRAHAMS, M.D. CANTAB.,  
M.R.C.P. LOND.,

TEMPORARY CAPTAIN, R.A.M.C.; OFFICER IN CHARGE OF MEDICAL DIVISION, THE CONNAUGHT HOSPITAL, ALDERSHOT.

IN considering the subject of heart affections as they are encountered in soldiers it will be desirable in the outset to say a few words about the term "soldier's heart," which has now acquired an accepted position in our nomenclature of diseases, one which certainly appears to supply a definite need in corresponding to a definite condition, but, unfortunately, also one which is employed with so much abuse that it is impossible not to regret that such a term should ever have been introduced. We ought to restrict its application to patients who are suffering from cardiac affections, or, at any rate, cardiac symptoms due in some way to military service. In this sense soldier's heart would be an occupation disease, as we speak of miner's nystagmus, scrivener's palsy, or housemaid's knee. But whereas there exists a special group of cases which in my opinion corresponds to such a restriction, even though the exact determining cause is still a subject for contention, the term is applied indis-

criminally to a large variety of symptoms which are evident in men who happen to be temporarily khaki-clad and most of which have nothing whatever to do with the heart, nor, for that matter, with military service.

And this reminds me to refer briefly to that question-begging epithet which is so conveniently employed in these days, D.A.H. (disordered action of the heart). Now, whatever words of depreciation may be considered suitable to apply in the case of the aforementioned "soldier's heart" these fade into insignificance when you select those condemnatory enough for its blood-relation D.A.H. I do not hesitate to say that I have seen men complaining of symptoms referable to every disease above the umbilicus sent in as D.A.H., and I am not at all sure that a certain number below this anatomical landmark have not been included. But even if one eliminates those cases of so-called D.A.H. which pass the first portal re-labelled N.Y.D. (not yet diagnosed) and are finally discharged as N.A.D. (no appreciable disease), what exactly does an honest attempt to use the words involve? What precisely is orderly action of the heart and when does chaos usurp the place of cosmos in the circulatory world? And in the second place is it not absurd at this stage of our knowledge of the etiology of disease to imagine that a diagnosis of tachycardia is a diagnosis, or that it is sufficient to say that a pulse is irregular or intermittent without taking the trouble to see what is the nature of the irregularity and if, as a matter of fact, its existence is of the slightest consequence?

In recalling to your memory the copious literature which has already appeared on the subject of "soldier's heart" during the last couple of years, I would suggest to you that a large variety of different conditions have been at various times described as if they were all the same thing. And I think the best way to support this proposition is to enumerate a representative collection of the causes which have been advanced.

First and foremost very naturally is the endeavour to ascribe all cases to exertion. Here, then, is our old friend "strained heart" or "athlete's heart" in modern form. To adapt the condition to military circumstances such features are introduced as marches with weights, shoulder-straps, and the other paraphernalia of service and service kit. The subject of heart-strain I will postpone to consider later in detail.

As a sort of corollary to this school there is another which presupposes the existence of a great deal of latent unsuspected cardiac disease which only manifests itself in consequence of the strain, physical or mental, or both physical and mental of military life.

To other authorities the condition is due to a toxæmia. If microbial influence is demanded—well, organisms are so easily introduced, from the teeth, for example, or from the food itself, and even if you are deprived of organisms there are always toxins to fall back upon. And if toxins likewise are denied, there are perverted products of metabolism, and some authors blame the excessive protein diet of the soldier.

Another large group of authorities attribute the condition to the thyroid gland. The majority of these think there is hyper-thyroidism, though a few believe the secretion to be normal in quantity, but of pathological quality. The soldier's heart to this school is simply larval Graves's disease.

At least every other week somebody writes to the medical journals explaining "soldier's heart" to be due to excessive cigarette-smoking, and considering the almost universal prevalence of this vice such an opinion has at least the support of reasonableness.

Recently "soldier's heart" has been attributed to deficiency of buffer-salts in the blood, and such an explanation is not without its inconvenience in view of the difficulty in technique in estimating these salts, more especially as I will be impudent enough to hint that the majority of us are more than vague as to what a buffer-salt is, what it does, and why its absence should produce symptoms of cardiac disease.

One turns next to an entirely different interpretation of "soldier's heart" in introducing the school which supports a psychical origin. Its disciples see no necessity to invoke the existence of any organic pathological cause. In fact, they see no necessity to suppose the existence of any sign of heart disease. They point out that the symptoms, although equally familiar in genuine heart trouble, are quite easily or at least speciously, explainable on a non-organic basis and that a

<sup>1</sup> A paper read before the Connaught Hospital Medical Society.

man who has hitherto adapted himself to the most sedentary life, suddenly forced into the activity of unaccustomed exercise, pants and puffs and finds it much easier to sit down than to try to keep going. The symptom of praecordial pain in such cases is generally indigestion due to bad teeth.

Now it seems to me that every one of these explanations is probably right—that is to say, that among the enormous number of cases one meets in the Army with symptoms of breathlessness on exertion, of praecordial pain, and of general so-called cardiac distress there are some which may be explained in every one of these ways. And if I may venture to criticise those of far greater experience to whom we look for guidance, I think they have often made the mistake of laying too much emphasis upon the particular condition they are describing to the exclusion of absolutely all else, and unconsciously, and of course unintentionally, giving the impression that they were dealing with the whole of the cases comprised under "soldier's heart."

I hold the view that the large majority of cases which are labelled "soldier's heart" and condemned as unfit for active service have a perfectly normal myocardium and suffer from symptoms which have no organic basis. I would, then, suggest to you that we may classify the cases which are sent up to us with symptoms or signs which might be referable to the heart in the following way:—

1. Functional cases. A large number of men at the outset of their military duties who are free from any organic disease, but who have hitherto been quite unused to any form of exertion and readily display symptoms of distress or of fatigue.

2. Cases with symptoms due to excessive smoking or other drugs and disappearing upon appropriate treatment.

3. Organic disease: (a) Valvular disease (1) compensated, (2) uncompensated; (b) myocardial disease; (c) adherent pericardium; (d) Graves's disease.

4. Genuine soldier's heart.

I shall not deal with these groups seriatim, but I shall refer to them indiscriminately in considering general principles.

The first general principle with which we should be concerned is the fundamental question of so-called *overstrain of the heart*. I would mention in passing that Sir Clifford Allbutt points out that this expression is tautological since all strain must be overstrain.

When one has the support of Sir James Mackenzie one need not hesitate to state dogmatically a disbelief in "heart-strain" or "athletic heart." As a matter of fact, on purely empirical and not clinical grounds I never have believed in it; but it is one thing to state what is regarded as a worthless opinion based on inexperience and differing from common acceptance, and another to express a point of view which receives the cachet of the doyen of cardiologists. And Sir James Mackenzie says of "athlete's heart":—

"Personally I have never seen such a thing and, when my opportunities of observation are considered, I think it will be allowed that I would have seen it if it had really existed." He says further: "I have had brought to me great numbers of young people of both sexes with hearts said to have been impaired by overstrain. I have not found a single case of dilatation with heart failure. That dilatation can be produced in a healthy heart as a result of overstrain, more particularly among the young and athletic, is a belief widely held. I am convinced that it is a view which is not justified. I never saw a single individual who suffered from heart dilatation as the result of over-exertion. I think I may fairly say that this was not due to inability to recognise overstrain."

With such a sentiment as the last is there anybody who will disagree?

I cannot lay claim to an experience which would justify me in the presumption of endorsing an opinion of Sir James Mackenzie, but I can at least claim a special experience which is in its way even greater than his. For eight years there has been practically no prominent athlete in any country in Europe (and a good many from the colonies and from America) whom I have not had an opportunity of examining before and after exercise. I have been hunting the "athletic heart" all this time in sprinters, middle-distance runners, Marathon runners, and I have never caught it.

And yet, it will be urged, our eminent predecessors published cases of dilated heart and overstrain which were clearly the result of exertion. In some cases a comparatively

recent antecedent infection is definitely stated, in others it is hinted at. And in others, again, a coincidence is well worth noting that both Sir Clifford Allbut and the late Sir Lauder Brunton describe cases of acute dilatation occurring during mountain climbing. Now the physiology of high altitudes is rather queer in itself; a large increase in red corpuscles has been shown to occur, and it is quite possible that by mere mechanical friction they retard circulation to some extent.

A priori there should be no expectation of the heart failing through pressure of work any more than of a diaphragm becoming fatigued. Nature is not likely to jeopardise the well-being of the most important muscle in the body but safeguards it by ensuring that everything else shall give in first. When a man is badly done up as the result of a big effort it is not cardiac failure but vaso-motor exhaustion from which he is suffering and his symptoms are due to nothing more serious. Personal experiences, however feeble, have at least a certain peculiar merit which is my excuse for obtruding these. During 16 years of practically continuous competitive athletics I have known frequently what it feels like to be badly run out or rowed out, but I remember only two special instances which stand out prominently. On the first occasion I had won a particularly hard 200 yards race and I can only attribute the nausea, dyspnoea, and dreadful headache from which I suffered the rest of that day as due to an extra effort induced by an exceptional keenness to win. Had I sought advice for my symptoms I might still be in bed or just beginning graduated exercises, but as this was the middle of a big athletic season I determined to adopt the best form of investigation I could think of, and the following morning I went out and ran, with very great relief to my doubts, one of the finest quarter-miles I have ever run. The second occasion was six years ago. Starting from Grindelwald, I went up the Faulhorn and down practically without a stop in four and a half hours. One hour after I had reached the bottom I began to experience intense nausea, and I fainted. I believe that these symptoms were due to the exhaustion from want of food. Once again alarm demanded a critical investigation, and 48 hours later I went up the Faulhorn as hard as I could go; but on this excursion I ate a good déjeuner, and rested for an hour at the top before running down, and I had not the slightest symptom of distress of any kind.

It is easy to understand how soldiers on the march faint, especially in hot weather, when their peripheral vessels are dilated to such an extent as to deplete the brain. Of course, some people are much more liable than others to these attacks from the particular tendency of their blood to drain into the large abdominal veins. Such attacks, too, are largely precipitated by the boredom of a march. The fatigue of disheartenment is a very well-recognised thing.

I put it to you that physical exertion is mainly a matter of will-power. Some men have the will to drive the engine harder than others. But, granting no flaw in the machinery, nobody can drive it to breaking point.

In the consideration of *organic disease of the heart* we have first to deal with the question of *cardiac murmurs*. Sir James Mackenzie says:—

"The presence of a murmur is often considered to be inconsistent with the idea of a healthy heart, and the great bulk of the profession and the teachers of the profession do adhere to this view." Further, he says: "Every graduate leaves hospital with but the vaguest notion how to assess the value of a murmur."

I think I may assert that there is not one of us here who does not almost every day see at least one striking example of the absurdity of worrying about the existence of a murmur qua murmur, a survival of student days when prolonged arguments were wasted upon the exact timing of some miserable squeak, to say nothing of the decision whether there was any murmur there at all. As a consequence we gained the impression from our teachers that the slightest alteration in the character of the heart sounds meant serious organic cardiac mischief, and the fruit of this teaching has been, in civil life, the obstacles placed in the way of such people ever getting insured, and in military life the wholesale rejection of perfectly healthy subjects physically fit for anything; so depriving the country of a number of efficient soldiers, and, what is even worse, condemning to a serious restriction of useful and wholesome

activity many men who for the rest of their lives walk about gingerly with the sort of sensation that they have a bomb inside them and with the perpetual dread of sudden death.

Now so long as the heart does its work properly what does a little music in its mechanism matter? Some motor engines purr, others bark, and others roar, yet all may be equally efficient; and the murmur in the heart may bear no more relation to the heart's capacity for work than, to continue the parallel, need a squeak in a spring have anything to do with the engine.

Many murmurs are, of course, not cardiac at all, but due to pressure relations of the pulmonary artery and the chest wall or to some other simple extra-cardiac cause. The distinction of physiological murmurs is usually quite easy if one is not wedded to the idea that heart disease is so common that it must always be suspected. And although organic murmurs must in any case denote a certain degree of disability, even organic murmurs are not necessarily of much consequence. As a convenient rule, Sir James Mackenzie has said that a systolic apical murmur may always be disregarded when there is no sign of enlargement of the heart, for, as he says, "if a murmur is caused by a lesion which embarrasses a chamber in its work, that chamber will alter in form either by dilating or becoming hypertrophied." So that to talk of V.D.H. (valvular disease of the heart) as a definite condition always calling for discharge from the Army as permanently unfit is quite unreasonable. To put it in the terms of a common pleasantry, there is V.D.H. and V.D.H. The heart's capacity for doing work is the vital criterion, and I am quite sure that many cases of well-marked valvular disease are little, if any, handicapped by their disability.

The heart muscle is, of course, the great factor in cardiac efficiency. If we could always measure the quality of the muscle we should find it easy to estimate the general condition of the heart, and the discovery of myocarditis with corresponding prognosis would be a simple matter. But a person's description of his inability to exert himself is, in my opinion, a very poor guide, although, as you are well aware, more than one cardiologist has stated that we are to accept a complaint of pain, dyspnoea, giddiness, &c., as absolute evidence of cardiac disability, even in the absence of abnormal physical signs in the heart.

As aids in estimating the cardiac efficiency, various tests have been elaborated—e.g., Grapner's; and various instruments have been invented, such as the Bock stethoscope, the application of which has been particularly encouraged of recent date by Dr. O. Leyton. The tests depend upon the differences observed between the pulse-rates and blood pressures in the resting state in the horizontal and erect positions and in the reaction to exercise. The Bock stethoscope is an arrangement which gives a numerical value to the audibility of the first sound at the apex and the second at the aortic base. A heart with normal musculature yields a ratio of 60:40. The nearer the ratio approaches unity the more the myocardium is pathologically affected. We have used the instrument fairly extensively here, and have come to the conclusion that it has a useful application. The chief difficulty in our experience is the necessity for absolute silence during observation, otherwise the error may be so great as to render the result quite useless. The instrument is said to be inapplicable when murmurs are present.

It is unnecessary to deal with the well-known signs of obvious cardiac distress—e.g., cyanosis and oedema. It might be thought that *dyspnoea* is equally obvious as a sign of cardiac inefficiency, but in this sign there is the possibility of a large functional element. The majority of the ill-fed, flat-chested, poorly developed men who enter the Army after an uneventful sedentary life and are then plunged into what is to them unalluring strenuous activity naturally puff and blow and complain of pain in the chest. Again, the *dyspnoea* of what I call a case of real soldier's heart is often an hysterical polypnoea and calls for vigorous physical and mental discipline.

*Pain* on exertion is, again, a very vague symptom. The pain complained of by false cardiopaths is usually praecordial and not substernal as in true angina, and the pain does not radiate. It often disappears after effective dental treatment, and especially if the man can be persuaded to overcome the inevitable distress of his first exertions and persevere. But once let a man get the idea that he has a weak heart and

any hypochondriacal "pain in his heart" speaks to him of sudden death. Speaking generally, we do not think of cardiac disease as associated with pain in the chest and when a man complains thus of his heart one is justified in thinking of his stomach.

It is one of the most important and often one of the most difficult things to decide the meaning of a *cardiac irregularity*. The general tendency is to regard any divergence from a perfectly regular rhythm as evidence of cardiac disease. But, on the contrary, some forms of irregularity are of no pathological importance whatever; indeed, one form, sinus arrhythmia, is even stated to be a particularly good sign that the heart is normal, a sort of hall-mark of a healthy heart. On the other hand, there are types of irregularity which give an absolute indication of serious myocardial change and their determination is far more useful than that of the size of the heart or of any murmur.

*Sinus irregularity* is a variability in the intervals of diastole. It can be produced in susceptible subjects by stimulating the vagus centre—e.g., by swallowing or deep breathing, for it is related to irritability of the centre. It can be completely abolished by exertion. Such an irregularity is, as I have said, of no pathological importance.

*Extrasystoles*, or, as they are more correctly termed, *premature contractions*, are recognised by the circumstance that the "extra beat" anticipates a regular contraction and is followed by a longer pause than after an ordinary beat. It is the long pause which is so unpleasantly apparent to the subject himself. Extrasystoles are often of no pathological consequence, and can be abolished by exercise. On the other hand, they may indicate myocardial disease. They constitute, therefore, one sign only which has to be taken into consideration with all the other cardiac phenomena.

*Pulsus alternans* is a condition in which alternate beats are of unequal volume. It is a very grave sign of myocardial disease. It is obvious that some care is necessary to distinguish this condition from one in which premature contractions occur after every full beat. In the latter there is always a longer pause after the weaker (the premature) beat. In *pulsus alternans* the beats are regular and the intervals equal.

*Atrial fibrillation* is a condition of irregularity in which beats vary in frequency and volume in a completely irregular manner. It is not decreased but generally increased by exercise, and it is a sign of serious organic disease.

*Heart-block*, in which the rhythm is disturbed at regular intervals by the dropping out of a beat, is always a sign of serious heart disease.

Whilst it is the rarest possible thing for a soldier to be sent up as D.A.H. with *bradycardia*, the number sent up as *tachycardia* far exceeds the total of all the other cases (I mean by tachycardia simply undue acceleration of the rate, whilst I would remind you that some authorities restrict the term to a special type of acceleration—*paroxysmal tachycardia*). Now to speak of tachycardia as a distinct condition, when it may be due to such diverse causes as acute peritonitis and drinking too much tea, is as absurd as to label a case abdominal pain when this symptom may be due to indigestion, appendicitis, caries of the spine, pneumonia, or a host of other things. In the first place, some people appear to have a physiological tachycardia and own a heart which runs normally at 110 perhaps and gives rise to no symptoms. When a patient complains of the usual cardiac symptoms it is clearly necessary to exclude all organic causes of tachycardia—e.g., tuberculosis, valvular disease, myocardial degeneration, adherent pericardium, Graves's disease, and any obvious functional cause, such as excessive smoking. We are then left with a residue of cases about which it seems impossible to decide, in whom there is nothing definitely organic unless you invoke larval Graves's disease. In this type of case there is, of course, no exophthalmos and no enlarged thyroid to aid the diagnosis, but the presence of tachycardia, of tremors, and of nervousness justifies one in diagnosing, according to inclination, larval Graves's disease or a neurotic condition with, as Sir Clifford Allbutt puts it, "a diffuse assemblage of mere accelerations."

And this brings me finally to what I think may legitimately be called *soldier's heart*. I premise as the patient a man who really has been a soldier and exposed to the vicissitudes of warfare. Is the influence of warfare, physical strain, toxin, or psychic trauma? The factor of strain I have done

my best to eliminate. A few words will deal with the other possibilities that have been raised. The patient presents symptoms generally of dyspnoea, always of fatigue on slight exertion, lassitude, persistent tachycardia without cardiac enlargement, and perhaps a variable number of neurotic manifestations. There is invariably a history of psychic trauma—it may be one acute occasion or a long-continued bombardment by greater or smaller shocks.

These are the cases for exhaustive investigation, for the detection of toxins, for the estimation of buffer-salts, for the consideration of the balance of the ductless glands, for inquiry into the previous psychical history.

It is unsatisfactory to invoke toxæmia, for surely this factor can never be eliminated and must play a part more or less in the production of any morbid state. The system is probably in a condition of auto-intoxication whenever it falls a victim even to psychic disturbances. In some of these cases the antecedent history clearly exhibits the presence of some infection—e.g., influenza, dysentery, or toxic state, such as constipation or some other cause of auto-intoxication. In other cases it does not.

As regards the ductless glands, I do not see how it is possible to deny or to prove their influence in this condition. What is the effect of their secretions upon the emotions? What is the influence of the emotions upon their secretions? Suppose the psychic disturbance does lead to some alteration in the glands, to the production, for example, of hyperthyroidism. Are we to suppose that such alteration is the principal result of the shock and that treatment directed to the gland will relieve symptoms? I personally have never seen the slightest benefit derived from this or, for that matter, any other form of treatment.

There is, it seems to me, a great deal to be said in favour of a purely nervous origin. In the first place, a very large proportion of sufferers are of a distinct type of mentality, men with shallow reservoirs of nervous energy—the neurasthenic soil, in fact. I yield to nobody in my admiration of the spirit which has animated the majority of sufferers from "soldier's heart" and all other forms of war neurasthenia when I describe them in this way. The symptoms correspond to a failure in vaso-motor and cardio-inhibitory control. The obstinate resistance to any form of treatment supports the idea of a nervous origin, a shock to the nerve centres which persists who can say for how long. It is a very striking feature that men who sustain a definite somatic injury do not manifest "soldier's heart," nor any other presumably nervous symptoms. In these cases of injury the immunity of the nerve centres to shock may be explained by the dissipation of the shock elsewhere, as the delicate works of a watch are spared in an accident in which the glass is smashed. It may even be explained, without detriment to the hypothesis of neurosis, by the mere circumstance of an injury having occurred satisfying the subconscious with the realisation of something definite, and not presenting to it only the sensation of some vague disturbance, the uncertainty of which prejudices recovery.

Reviewing, with not unnatural pessimism, the persistence of symptoms, one cannot help thinking that only termination of hostilities could cure these sufferers, in whom with the best of intentions there must continue to run a subconscious current of defence-neurosis telling them that recovery means a return to the hell from which they have escaped. Treatment of such cases appears to have the sole effect of perpetuating their neurosis by fixation of the attention, although whether immediate vigorous treatment of them as of purely neurotic origin would yield better results we here have no opportunity of observing. since the cases we see are, so to speak, chronic who are left in *status quo* after a great deal of practically every form of therapy that has been recommended. As we see them, at any rate, such cases are of no further use for general service, but given sedentary work they continue on a low level of activity with the tachycardia and other symptoms unrelieved, but, so far as we can see, executing very light duties with comparative cheerfulness and apparently without any ill effects.

ST. AUSTELL (CORNWALL) BOARD OF GUARDIANS AND THE TREATMENT OF ADENOIDS.—At the last meeting of the St. Austell board of guardians it was decided that Dr. A. Shaw should operate upon children requiring the removal of adenoids at a fee of 1 guinea per patient.

## IMPORTANT PRINCIPLES IN THE DRAINAGE AND TREATMENT OF WOUNDS.

BY WILLIAM PEARSON, F.R.C.S. IREL.,  
MAJOR, R.A.M.C. (TEMP.).

*With Remarks by P. J. FREYER, C.B., Lieutenant-Colonel, I.M.S. (R.), Consulting Surgeon, Eastern Command.*

AN experience of more than two years of war surgery, with considerable study of its literature, has convinced me that no general agreement in the principles of wound treatment has yet been reached amongst surgeons. My time has been spent first in France and subsequently in England, and several thousands of cases have passed through my care, so that I feel I can speak with some authority on the behaviour and progress of various types of wounds in both their early and later stages. This dual experience is, I believe, of value in helping one to form a clear judgment on the merits of different lines of treatment, because it has appeared not infrequently that the views of workers in France and of those in this country are at variance; and it has been suggested that these differences are due to the different conditions under which the work is performed, or rather to the different stages in the life-history of the wounds at which treatment and observations are carried out, so that both may be right, and what is sauce for the goose is *not always* sauce for the gander. I do not believe that this is a satisfactory explanation, as the general lines on which I was working when I left France two years ago are, with slight modifications, those that I still employ with excellent results. The modifications have not been changes of principle, but rather a further advance on the same lines.

Naturally a very large amount of the work and literature on wounds has been devoted to the questions of infection and sepsis and their treatment; and it is not uncommon to hear it said that our ideas on these subjects were previously all wrong, and that we have had to change both ideas and methods entirely. Infection and sepsis are no new things; the differences between them as seen in war wounds and in civil practice are differences of degree and character only, so that if the previous statement is correct it follows that heretofore surgeons have been working on altogether wrong principles in dealing with them. But this is manifestly incorrect, as evidenced by our enormous strides in dealing with intra-abdominal infections, to take only one example. "*Ubi pus, ibi evacua*" is a surgical maxim which is as generally accepted as it is old, and all surgeons are agreed on the necessity for drainage in dealing with sepsis.

### *Claims as to Value of Antiseptics and Concentrated Saline.*

Concerned with this question of drainage are two schools—I had almost said factions—which hold different views as to how drainage may best be aided in subduing infection. The members of one, which may be termed the "antiseptic school," pin their faith to the use of antiseptic solutions by which they believe they can rapidly diminish or destroy the organisms *in situ*, and thus subdue the sepsis and even render the wound sterile. The doctrine of this school amounts to an admission that by drainage alone they are unable to effect satisfactory results—in other words, as I shall indicate presently, that their drainage is faulty or inadequate. The weakness of their position is indicated by the truly astonishing number and variety of antiseptics which have been advocated for this purpose in the medical press of the past two years. From amongst them the hypochlorite group, exemplified by "eusol," may be taken as being the most fashionable at the present time.

The other school, ably led by Colonel Sir Almroth Wright, may be called the "concentrated saline school." It maintains that by antiseptics it is impossible to destroy all organisms in the wound once infection is established short of destroying the tissues themselves, and that infection and sepsis are best combated by promoting free secretion into and discharge from the wound, making use of a concentrated saline solution for this purpose. Whether this acts by osmosis or in some other way is really immaterial to the issue, provided it is effective and necessary. The solution advocated by Sir Almroth Wright is

one of sodium chloride 5 to 10 per cent., and it has been enthusiastically supported by many surgeons both in this form and in its modification known as the "salted pack," which consists of a gauze pack in which are incorporated solids of sodium chloride. While fully appreciating the value of Sir Almroth Wright's work, and recognising that through it he has been demonstrating and emphasising the importance of drainage, the lessons to be learnt by practical surgeons have, I believe, become somewhat obscured by the undue prominence given to the rôle of the concentrated saline, both in his writings and in those of other supporters. Indeed, that this is so was made manifest to me by the remark of a distinguished surgeon, when discussing with me the "salted pack" and advocating its merits a year ago. He said: "It is extraordinary the way it works; it seems to have a remarkable instinct in causing a profuse discharge in the very cases in which it is necessary, and causing very little in others where it is not required." Assuredly, the "remarkable instinct," prompted by the organisms, was exercised by Nature and not by the salt in the pack.

Unfortunately the brilliant advocacy of "concentrated saline," and more recently of "eusol," has possibly done harm. I am convinced that through it, in the minds of many, the main issue has become obscured, and that the paramount importance of good mechanical drainage has been lost sight of. It is, even still, not an uncommon thing to receive a patient, whose wound is in a bad state of sepsis and most inadequately drained, adorned with a label on which one reads, "washed out with concentrated saline twice daily"; "irrigated with Wright's saline every four hours"; "treated with salt packs"; or, "treated with eusol—wounds now beautifully clean." I quote from actual cases received under my own care; the latter case in particular I remember for its cheery optimism, as it was what I would describe as "full of sepsis." I am fully aware of the magnificent surgical work that is being done in France, of the very difficult conditions under which it is often performed, and of the fact that these cases had probably not been dressed for 24 hours when we received them. I only instance them to show that in the minds of some, at least, the value of good mechanical drainage is not fully appreciated, and the use of concentrated saline or the latest fashionable antiseptic is given the *seat of honour*.

#### *Importance of Free Mechanical Drainage.*

Two months' work in France at a base hospital sufficed to convince me that the use, in a wound, of the antiseptics which were then in vogue was valueless in subduing infection at the time when this was the all-important indication for treatment. I became convinced that the secret of success lay in free mechanical drainage; nor have other measures since advocated, and which I have given a fair trial, caused me to change my opinion.

It is, of course, universally agreed that sepsis cannot be dealt with adequately either by antiseptics or concentrated saline if unsupported by drainage; but it is not, I think, generally recognised that wound infection can be thoroughly and efficiently controlled by mechanical drainage without the use of either of these aids in the wound itself. And yet I am convinced that this is so, and that the results are equally prompt and satisfactory. Of such paramount importance is good free mechanical drainage, that when this has been properly established it is a matter of indifference whether we employ antiseptic solutions or concentrated saline as an aid, and the value of either is so subsidiary as to be negligible. I will not assert, as some have done, that they are injurious—I have formed no definite conclusions on this point—but I do say that they are unnecessary. The greater my experience in wound treatment the more I am convinced of the truth of this, both from my own personal observations and from my knowledge of the work (sometimes in an opposite sense) of others. *Mechanical drainage is the essential factor in the successful treatment of infection, and success will be directly proportional to the mechanical efficiency of the drainage.* The question which every surgeon should ask himself, when faced with a case which is not progressing satisfactorily, is, "What is wrong with the drainage system in this wound?" Almost invariably the answer will supply the key to successful treatment, if we exclude, of course, cases of severe systemic infection, gas gangrene, and so on, which fortunately form only a small proportion of our cases. Even these will become greatly

reduced in number by the early establishment of adequate drainage.

Unfortunately we meet here with the difficulty of the personal equation in the surgeon: what one may regard as adequate another may think quite insufficient. But it may help somewhat to state that *what is sufficient drainage in the common infections of civil practice is usually totally inadequate when dealing with a wound infection of similar magnitude*, and that it is impossible to over-drain. Indeed, as a general rule, the freer the incisions the more quickly and satisfactorily is the wound healed, a fact which is not apparent at first sight.

Numerous cases might be quoted where, in spite of weeks of treatment, progress was being retarded or the patient going steadily to the bad from want of mechanically efficient drainage; but it will be more to the purpose to point out the more common faults in drainage as I have observed them. They are: 1. Insufficiently free incisions. 2. Drainage against gravity, without counter-openings, especially in thigh, arm, and shoulder cases. 3. Too small, improperly adjusted, or improperly used drainage-tubes. 4 Mechanical obstructions within the wound, such as small or valvular openings from "pockets," hernial protrusions of lacerated tissue (especially muscle), foreign bodies, bone fragments and débris, tight gauze packs. 5. Obstruction external to the wound, such as tight bandages, pressure from splints, bedding, &c.

In the vast majority of cases the complications and sequelæ of sepsis may be avoided by the institution of timely drainage on sound mechanical principles; and their occurrence should usually be regarded, not as "bad luck," but as an indication that in some way or another the drainage system has been at fault.

#### *Mechanical Principles Involved in Drainage.*

Recognising the paramount importance of drainage, and remembering that from an operative point of view it is merely a mechanical problem, our efforts to render it efficient must be directed in accordance with simple physical laws. Though these are well known, I wish to consider them briefly with special reference to their practical application to projectile wounds. The chief factors governing the efficacy of drainage are then: (1) Absence or reduction of resistance to outflow; (2) gravity; (3) capillary action. The first two of these are closely connected.

1. The freer the exit the less is the resistance offered to the escape of discharges from the wound. This shows the necessity for *free incisions* in dealing with infection, particularly in deep wounds. Our aim should be to convert these into cone-shaped openings, the base of the cone being situated at the surface, so that free exit is obtained from all parts of the wound; pockets and tracks should be thoroughly opened up; "tunnels" should usually be laid open throughout unless anatomical considerations forbid; obstructions within the wound should be removed, so that good access and free exit are established throughout. The necessity for extensive surface openings is *very much greater in the case of infections in projectile wounds than in those of civil practice*, so that it is evident that there is something more than the mere question of free exit involved. The explanation is to be found, I believe, in the nature of the infecting organisms, which usually contain large numbers of anaerobes in the former.

Free drainage in the wound itself will not avail if the outflow is obstructed externally, and therefore attention should always be paid to this matter. Dressings should not be applied tightly, splint pressure must be carefully avoided, and the patient must be disposed in bed in such a way that no pressure is exerted over the wound. These are points which are frequently neglected, and it is difficult in the course of a paper to frame rules for every case. Briefly, however, I may point out that wounds in the posterior surfaces of thigh or leg should be treated by slinging the limb from a Balkan splint or leg cradle; in back and buttock wounds the patient should be placed on a "spinal bed" or framework with removable canvas "slats," so that pressure against the wound may be avoided—failing such an apparatus the patient should be kept in the lateral rather than in the dorsal position; wounds of the upper limb may often be conveniently treated by suspension in a Thomas' knee-splint or from one of the more elaborate devices.

2. The value of gravity and the use of counter-openings as an aid to drainage are not, I think, sufficiently appreciated in practice. This is particularly so in cases of wounds on the front of the thigh with, perhaps, a compound fracture of the femur. In these it is not uncommon to find, even after weeks of treatment, that the only exit is an overflow, that the whole wound is a foul cesspool of pus which has tracked extensively in the limb, and that there is widespread necrosis of the bone and complete absence of union in the fracture. Such a condition can easily be avoided if in the first instance, no matter how free the anterior opening may be, a good counter-opening is made into the deepest part of the wound—preferably, in thigh cases, from the postero-external aspect of the limb.

In extensive wounds with much laceration of tissue it will frequently be necessary to make several counter-openings to deal with different recesses or "pockets," but the surgeon should have a definite purpose in view for each opening he makes; it must never be made by "rule of thumb" but to suit the exigencies of the particular case. The efficient drainage of each individual wound is a problem in itself which should be governed by definite principles indeed, but the details of which depend on the exact characters of the wound. Often it is a simple matter and can be determined at a mere glance; at other times it becomes one of great complexity and cannot be solved without thorough digital exploration and inspection of the wound on the operating-table. Even then anatomical considerations may prevent one from following the most efficient mechanical plan, and one has to adopt something less. But what I wish to emphasize again is that *no other measures which we may employ will adequately replace a mechanically perfect system of drainage.*

3. Capillary action, though of less importance than free exit and gravity, is also a valuable mechanical aid in promoting drainage; it literally "draws" the discharge. In employing gauze wicks and packs for this purpose it is important to observe the following points:—

(a) The gauze should extend into the various parts of the wound, which should be filled up evenly and with but moderate pressure throughout; it should constitute what I term a gauze "fluff," and not a tight pack.

(b) Dead spaces should not be left within the gauze or between the gauze and the walls of the wound, as they will favour stagnation and decomposition of the discharge and form an excellent culture-ground for bacteria.

(c) In order to maintain capillary action it is necessary to prevent water-logging of the gauze drain. Hence we should allow evaporation to take place, and should never employ a waterproof covering over the dressing during the period of profuse discharge. For this reason, too, external dressings of gauze will be much better than close substances such as lint. The time-honoured boric fomentation is to be vehemently condemned at this stage, as it rapidly becomes merely a pus poultice, but unfortunately its use is still common. Copious coverings of wool and the application of firm, heavy bandages should similarly be avoided except for purposes of transit. The use of large quantities of wool for the purpose of soaking discharge should also be condemned on grounds of economy, as much of the wool now in use is anything but absorbent, and discharges merely track along inside the dressing to find their escape in the bedclothes. If the external gauze dressings become saturated they should be changed immediately.

(d) It is in the acute virulent stage of infection, when the discharge is usually profuse and serous in character, that capillary action is an effective aid to drainage; it is of no value when discharge is thick and purulent. If gauze packs are used then, and if discharge is profuse, they become clogged with secretion in a short time, and acting as foreign bodies merely delay the cleansing of the wound. This does not mean that gauze packs should never be employed in the later stages of wound treatment. They have very important uses then, too, but chiefly not for drainage purposes. Space does not permit of dealing with these uses here.

Incidentally I may remark that if a wound is thoroughly cleansed of foreign material and dead tissue and efficiently drained on the lines indicated, the change in character of the discharge from thin serous to thick purulent is accompanied by such a diminution in amount that there is no stage in which we find a profuse purulent secretion. The

occurrence, and particularly the persistence of the latter, should always lead one to suspect either a foreign body, dead tissue (especially bone), or defective drainage. Indeed, many flesh wounds treated on these lines clean up rapidly within a week, so that it is difficult to say that there has been any purulent stage, and they may readily be closed by secondary suture or strapping with adhesive plaster.

#### *Aids to Mechanical Drainage.*

1. *Uses and abuses of drainage-tubes.*—A drainage-tube should be employed where a dead space cannot be avoided by gauze packing, or where dead tissue is present whose complete removal is inadvisable during the early stages of infection (e.g., most compound fractures), so that a prolonged period of free discharge is anticipated. The tube should lead down to this point, and it may often lie conveniently in the midst of the gauze packing, so that it does not come into contact with the walls of the wound. It must, however, act in the direction of gravity, if possible—through a counter-opening, if necessary. Through the tube a gauze wick may be introduced with advantage while the discharge is serous in character. Occasionally it is useful to keep both tube and wick long, so that they project for some distance from the wound and in this way exert an increased syphonage or suction action on the discharge and convey it to a convenient receptacle.

In deep wounds where neither dead space nor necrotic tissue exists, but where the escape of discharge is in an upward direction, a tube should be led through a dependent counter-opening into the deepest part; or the wound may be enlarged in such manner that gravity no longer hinders but will favour drainage. Where neither measure is feasible a tube should be led directly through the wound to its deepest part, and through it discharge should be aspirated as it accumulates.

Tubes are also useful for purposes of irrigation in deeper parts, particularly in comminuted fractures with necrosis, where there is always some tendency to retention and decomposition of discharge between the bony fragments. Here, unless the exit is exceptionally free, it is convenient to employ two tubes—one for injection and the other for return of the fluid. These may lie side by side (the "doubled-barrelled" tube) in the wound down to the fracture, but are often more efficacious when introduced from opposite sides—one through a counter-opening. In this way accumulated stale discharge can be washed away thoroughly at frequent intervals.

Another use for drainage-tubes, apart from treating infection, is in maintaining the patency of openings in the soft tissues when they show a tendency to close too quickly to permit of sound healing in a deeper part. Examples of this in connexion with bone cavities of moderate size, after necrosis has been eradicated, will not infrequently occur and need not be alluded to further.

Care must always be taken to select, trim, and insert a drainage-tube to suit the particular requirements of the case. Within limits, the larger the bore of the tube the better. The tube should be introduced *down* to the area to be drained, but *not through it*—the importance of this has been previously pointed out by Colonel H. M. W. Gray.<sup>1</sup> Great care must be exercised to prevent the end-opening of the tube from being occluded by contact with tissue, and a useful method to prevent this is to cut it in a "fish-tail" manner. Superfluous side openings should never be used, and the practice of employing tubes in which these have been made previously haphazard by the theatre sister is to be condemned. When cutting a side opening there should always be some definite purpose in view, such as the escape of discharge from some more superficial plane or area, and it should be placed accurately at such level and in such direction as will ensure its efficiency. It is common to meet with cases of through-and-through wounds of the thigh, arm, or leg, with considerable laceration of muscles and a severe comminuted fracture in which the only attempt at drainage has been the insertion of one long drainage-tube right through the limb and fracture, with a few lateral openings cut anywhere and lying anyhow up against the walls of the wound. This plan is never efficient, and should not be adopted.

The danger of pressure necrosis from a drainage-tube must always be remembered. For this reason tubes must

never be a "tight fit," either a smaller tube must be used, or, more frequently, the opening should be enlarged. It is always advisable during the acute stages of infection to insert gauze between the tube and the surrounding tissues. On no account should a drainage-tube be left in contact with the wall of a blood-vessel; otherwise secondary haemorrhage is almost a certainty. Contact with nerves, ducts, and other important anatomical structures should also be avoided.

Superfluous drainage-tubes should not be employed, and as soon as a drainage-tube has fulfilled its functions it should be discarded. It may seem unnecessary to say this, and yet there appears to be an idea amongst many that a drainage-tube in a septic wound, even if it is not doing much good, is at any rate not doing any harm. There comes a time in the treatment of every wound when the retention of a drainage-tube is doing harm: a tube is at all times a foreign body, and thus its presence is injurious unless the advantages derived from it outweigh its disadvantages. Its primary use in infections is to maintain a free exit for discharges until the infection has been subdued sufficiently to enable us to dispense with it. Its presence may retard as well as favour healing. More than once I have seen a tube retained in a long narrow track which for weeks past had been "crying out" to be allowed to close, and the removal of the tube resulted in complete healing in a few days.

**2. Exposure to air.**—The advantages of loose dressings and their exposure to the air to prevent saturation and stagnation of discharge and to favour drainage by capillary action have been mentioned already; but exposure of the wound itself is sometimes of special value.

In the early stages of severe infection, when first a wound has been opened up, I have sometimes found it advantageous merely to cover the wound with one or two thin layers of gauze, which are laid *evenly in contact with the surface all over*, and to use a bed of dressings on to which the discharge runs. This is best suited to widely gaping or open wounds such as the raw ends of septic "chopped-off" amputation stumps, and I know no method by which they clean up and become covered with healthy granulations more quickly. Presumably, in addition to the continuous and thorough removal of all discharges, this method has the advantage of combating anaerobic infection very effectively, and I have termed it the "local open-air treatment." I frequently adopt this method also for a few days in the later stages of treatment as a preliminary to secondary suture and skin-grafting, and I believe it is of real value.

**3. Irrigation.**—Continuous irrigation has been recommended by many, and is undoubtedly a means of effecting a constant removal of waste products. But it is at best in most cases a troublesome method to carry out; it is impracticable when dealing with large numbers of patients, and I do not think it yields better results than *good mechanical drainage* without its aid. For these reasons I have rarely employed it. Irrigation of the wound should, however, be performed when packs are being changed, as it not only helps to loosen the latter, but also removes any residual discharge and "floating" organisms. It is also useful for washing away discharge at intervals from areas which otherwise cannot be thoroughly drained (e.g., between bone fragments).

**4. Use of concentrated solutions of salts.**—Sufficient has been said before to indicate that I do not believe in the efficacy of this method. When drainage is carried out on proper mechanical lines it is quite unnecessary, and I cannot satisfy myself that it either increases the discharge or hastens cleansing of the wound. And here I must allude to an admirable paper by Captain J. E. H. Roberts and Captain R. S. S. Statham on "The Salt Pack Treatment of Infected Gunshot Wounds."<sup>2</sup> It is certainly the best paper I have read on the general treatment of wounds, and I can readily credit the excellence they claim for their results. But I think they have been unfortunate in the title of their paper and that they attribute their success rather to the wrong quarter. Their methods of drainage are very similar indeed to those which I have advocated here, and which I have employed now for two years, and I am convinced that their results will be equally good if they abandon the use of the salt in their packs.

**5. Administration of fluids to the patient.**—The discharge from a wound which is its natural irrigant is derived from the body fluids. When the discharge is profuse these fluids will rapidly become depleted and the discharge will diminish, and the elimination of waste products and toxins by the kidneys will be reduced unless we maintain the source of supply. Herein lies the value of the free administration of fluids in cases of severe sepsis.

The late Dr. J. B. Murphy, of Chicago, clearly recognised this in advocating proctoclysis in the treatment of general peritonitis, and he suggested that its mode of action in producing a natural irrigation of the peritoneal cavity was by transference of fluid from the lumen of the bowel to the lymphatics, thereby causing a "reversal of the lymph flow in the peritoneum, so that the latter became a secreting and not an absorbing membrane." But it is surely more probable that the "reversal of the lymph flow" is merely the natural protective inflammatory exudate, which is *maintained and increased* by sustaining the body fluids to the full. In this way we see the application of the principle of fluid administration to all cases of infection as an aid to drainage. In severe cases with marked toxæmia, where shock or much loss of blood may be anticipated at operation or where very profuse discharge is to be expected afterwards, saline infusions should be given on the operating table and rectal salines should be administered subsequently; in less severe cases rectal salines alone will suffice. In all cases the patient should be allowed unlimited fluids by the mouth, provided the stomach will tolerate them. The free exhibition of fluids will largely prevent or remove the pinched, shrivelled look of severe sepsis; it will give the patient a general feeling of well-being, it will allay the appalling thirst, and it will maintain a free discharge from the wound until the infection is subdued.

#### *Uses of Antiseptics in Wound Treatment.*

Personally, I consider antiseptics valueless as a means of disinfecting a wound once infection has become established, but nevertheless they have their uses in wound treatment. They prevent stale discharges from becoming a breeding ground for bacteria, and so diminish the risk of infection spreading or being conveyed from one wound to another. Consequently they should be employed in the gauze dressings into which the wound drains, and should also be used in irrigating lotions. Soiled dressings should be placed in a receptacle containing some antiseptic solution when they cannot be burnt immediately. It matters little or nothing what antiseptic is employed, provided it is cheap and efficient and has no particular disadvantage; substances irritating to the skin, such as mercurial salts, should be avoided in the dressings. For irrigation I prefer a lotion containing peroxide of hydrogen, as it possesses special mechanical properties in loosening dressings and packs and in removing débris from the wound.

In the later stages of wound treatment antiseptics may be put to many uses to promote healing. But they are employed then, not for their antiseptic properties, but rather as caustics, astringents, or stimulants to control and direct the growth of granulation tissue in proper directions—a process which may be termed "coaxing the wound."

#### *Vaccines.*

Like most observers, I have not found vaccines helpful in dealing with infections in wounds of war. Perhaps the type of case in which resort to them is still most frequent is one of chronic sinus which has obstinately refused to heal. I believe that in every case of persistent sinus the obstacle to healing is *local and mechanical*—a sequestrum or focus of caries, a foreign body, drainage against gravity, too small a surface opening, callous rigid walls, or degenerated granulation tissue—and that the correct treatment is to deal with it accordingly. I know of one case in which a sinus persisted for nearly a year following a simple flesh wound in a limb. Eventually the surgeon was about to resort to vaccines, but a skiagram revealed the presence of a bullet in the muscles.

#### *Rest.*

The importance of maintaining the injured part at rest has been previously emphasised by other writers, and therefore needs only passing reference here.

*Removal of Loose Bone Fragments.*

Differences of opinion have been expressed as to the removal of loose fragments in the early stages from a septic comminuted fracture in view of the danger of non-union. I think the general tendency has been towards insufficient removal and that the danger of non-union is over-rated. In these cases we meet with three types of fragments which, according to their size, may conveniently be termed "fragments" proper, "gravel," and "sand." "Gravel" and "sand" should always be removed as thoroughly as possible; they merely form masses of necrotic débris in which discharge stagnates and organisms flourish. "Fragments" proper should be removed when they retain no connexion with periosteum and soft parts, as they are then avascular and completely necrotic. Fragments which retain their vascular attachments may be left *in situ*, provided that their presence does not impede free mechanical drainage, especially from the medullary cavity. Only one case of non-union has occurred in hundreds so treated.

*Complications of Wound Healing.*

I desire briefly to allude to two of the most important complications which one meets in dealing with wounds:—

1. *Deformities from muscular contractures.*—Muscles which are the seat of inflammation are liable to become permanently shortened, and so to lead to crippling deformities, especially in the limbs. Such deformities are usually easy to prevent but difficult to cure. Consequently we should guard against them from the start, and maintain the limb in suitable position. Contraction of the hamstrings with permanent flexion of the knee, and of the calf muscles with drop foot, are amongst the most important; corresponding conditions may occur in the upper limb. If injury to muscles is likely to impair or destroy the mobility of a neighbouring joint, the joint must be kept in the position in which it will be of the greatest use subsequently.

2. *Secondary haemorrhage.*—This is almost invariably an indication that the drainage of a wound is faulty. Consequently it should not occur subsequently to operative treatment for infection, and it will practically disappear if we effect adequate mechanical drainage in the early stages. When it has occurred the case must be submitted to operation without delay, otherwise recurrence is a practical certainty. In every case where it is anatomically possible the wound should be explored and the source of bleeding found and dealt with directly by ligation of the vessel on both sides of the erosion, choosing a healthy part of the vessel wall. Faults in drainage should also be rectified at the same time. Packs and such measures should only be used as immediate temporary means of control; they lead to a false sense of security and are often ineffective in controlling the bleeding. Turpentine I regard as useless and even dangerous, as it may lead to increased sloughing in the tissues. Proximal ligation at some distance from the wound should never be adopted where direct treatment is possible; it may fail to control the bleeding primarily, and it is no safeguard against recurrence.

Subsequently to operation secondary haemorrhage has, in my experience, been remarkably rare. It has only occurred in four cases—i.e., 0·25 per cent.—and I attribute this entirely to the methods of drainage employed. These cases are instructive as showing the cause of the haemorrhage. In the first case, which occurred early in the series, the posterior tibial vessels yielded behind the lower end of the tibia, probably from the pressure of a drainage-tube. This is the only fatality I have had from haemorrhage; the patient never rallied and died in less than two hours. In the second case, at operation for extraction of shell from a deep lacerated septic wound in the middle of the thigh received some ten days before admission and in which drainage was against gravity, the femoral artery was felt pulsating in the wall of the wound. The question of ligature was considered and rejected, but the vessel gave way 36 hours later. In the third case the brachial artery was perforated some three weeks after operation by a projecting spicule of bone on the upper fragment of the humerus, which was comminuted in its upper third. The fourth case was a difficult one of comminuted fracture of the lower third of the humerus with severe infection, in which anatomical considerations prevented adequate drainage in the direction of gravity. Here the ulnar artery yielded in the antecubital fossa.

I have operated on some 15 other cases for secondary haemorrhage, and in each there were obvious mechanical faults in the drainage.

All cases (except that first quoted, where the patient was moribund when haemorrhage was controlled) have been treated by direct ligation on the lines indicated. In none was there any recurrence of haemorrhage and all patients made good recoveries.

The opinions expressed in this paper are the results of close personal observation and practice of war surgery extending now over a period of more than two years, and I believe that a more general recognition of the principles advocated, with their thorough application to all cases of infected wounds in their early stages, will help materially to improve our results and hasten the recovery of our patients. That good results can be obtained by these methods the following brief facts will, I think, bear witness:—

1. Out of all cases treated there has been only one death from sepsis. This was a very severe compound fracture of the upper end of the femur; the patient was already overcome with toxæmia when received, amputation was not practicable, and death occurred on the following day.

2. There was one death from gas gangrene, which developed rapidly in the upper half of the thigh. A high "guillotine" amputation was immediately performed, but it was impossible to get beyond the infected area.

3. Apart from three other cases of gas gangrene, in which amputation was successfully performed, only four amputations—all successful—have been done to save life. Three of these patients had been wounded some considerable time before coming under my care; the fourth had been literally riddled, and 22 shrapnel balls had been extracted (at three sittings) before it became necessary to amputate through a knee-joint eight days after he had been wounded.

It is questionable whether some of the limbs saved were worth preserving from a functional point of view, but this does not affect the results.

4. Two cases of tetanus occurred and both patients recovered under treatment.

*Conclusions.*

1. Efficient mechanical drainage is the essential factor in the successful treatment of infection.

2. The cardinal principles governing drainage are: Freedom of exit; gravity; capillary action.

3. Drainage-tubes should not be employed unnecessarily. They should effect the purposes for which they are used, and should not act injuriously in the wound.

4. Dressings should not be tight, of close texture, or waterproof. They should be exposed to the air while discharge is profuse.

5. Continuous irrigation aids disinfection by mechanical removal of discharge. It is usually not feasible when dealing with large numbers of cases. It is not necessary in order to obtain good results.

6. Free administration of fluids to the patient is an important adjunct in the treatment of sepsis.

7. The value of concentrated saline solutions and antisepsics as aids to disinfection is doubtful and negligible.

8. The use of salines and antisepsics in no way diminishes the necessity for free mechanical drainage.

9. Vaccines are not helpful in dealing with infections in wounds of war.

10. Rest is an important factor in wound treatment and should never be neglected.

11. Most of the complications and sequelæ of infection are due primarily to inefficient mechanical drainage, and are therefore preventable.

12. Delay in healing is almost invariably due to local mechanical causes.

My best thanks are due to Lieutenant-Colonel P. J. Freyer for the interest he has taken in my work and the kind remarks he has made on my paper.

*Remarks by Lieutenant-Colonel P. J. FREYER.*

Major William Pearson has invited me, as consulting surgeon to the Eastern Command, and therefore intimately associated with him in the work of the large war hospital to which he is surgically attached, to offer some observations on his paper on "Important Principles in the Drainage and Treatment of Wounds." Whilst readily complying with his request, my observations will be brief, for the simple reason that I entirely endorse the views enunciated by him, and

that anything I might say on the subject has already been simply, clearly, and forcibly expressed in this essay.

As my mission in this war has been mainly consultative, and only to a minor degree operative, I have had ample opportunities in passing under review tens of thousands of wounds of all types and degrees and of comparing the methods and results of other surgeons, many of them amongst the ablest in the profession, and all actuated by the desire to place at the disposal of their patients what they considered the best methods of treatment. The "supersaline" treatment with its paraphernalia was much in vogue in the early days of the war, but has been gradually disappearing from the stage. Antiseptics innumerable have, of course, been employed, and successfully employed, I have noticed, in proportion to the adequacy of the accompanying drainage. At my first visit to Major Pearson's wards, containing some 500 beds, I was much struck by the simplicity of the dressings and the thorough mechanical drainage of the wounds. Each subsequent visit confirmed me in my admiration of the surgical methods employed and the results obtained therefrom. I can honestly say that I have never seen better surgical work than that accomplished by the simple methods described in this paper.

## THE INFLUENZA EPIDEMIC OF SPRING, 1915; WITH SPECIAL REFERENCE TO ANOMALOUS THROAT SIGNS.

BY A. GEOFFREY SHERA, B.A., M.B., B.C. CANTAB.,  
M.R.C.S., L.R.C.P. LOND.,

LATE LIEUTENANT, R.A.M.C.; OFFICER IN CHARGE OF PATHOLOGICAL  
DEPARTMENT, CENTRAL MILITARY HOSPITAL, KASBOURNE; LATE  
CLINICAL ASSISTANT, MEDICAL OUT-PATIENT DEPARTMENT,  
EVELINA HOSPITAL FOR CHILDREN, S.E.

### Introductory.

THIS paper is a résumé of observations on some 500 cases of influenza in civil practice in South London, occurring about two years ago; time having hitherto been otherwise occupied, these observations could not be sent to the press until now. At the end of 1916 we were faced with the same perennial visitor, and to demonstrate its vagaries this paper should make possible a comparison between the syndrome of spring, 1915, and that of the last months of 1916.

It must primarily be remembered that the influenza germ is certainly responsible for a variety of lesions, dissimilar in almost every epidemic and in almost every locality, yet retaining certain common traits. For instance, the older physician scarcely recognises the modern type of influenza as his old friend the "knock-me-down fever," and therefore is apt to overlook it, if not to despise it as unworthy of much attention. Yet I venture to state, and herein hope to show, that the clinical and bacteriological phenomena associated with this complaint are a study worthy of much attention and as yet largely unfathomed, in spite of the enormous literature on the subject.

At the onset I wish to state that although the cases of the present epidemic appear to be rather more severe, they present many of the phenomena which I am about to describe.

### General Description.

Adopting the older classification of catarrhal, nervous, and abdominal types, one could describe the cases of the 1915 epidemic as partaking of a combined catarrhal and nervous type. The abdominal type was almost completely absent. All these cases presented in the first stages a vesicular eruption on the soft palate, fauces, and posterior pharyngeal wall, with erythema of the mucous membrane, and were generally followed by neuralgias or other nervous phenomena. The initial symptoms were mild, but complications were frequent and varied. The catarrh was protracted and the nervous system slow in resuming its normal tone.

To sum up, one might describe the syndrome as a febrile catarrh with a secondary neurotoxic lesion as its most prominent complication. Later statistics will be given and these lesions classified. Before going further it will be well to have a clear clinical picture.

A typical case was that of a man, aged 25, a smoker. The patient was in contact with several folk afflicted in this

epidemic. At first he had a feeling of malaise, with muscular pains in the limbs, especially the thighs, also frontal headache and disinclination for work. That evening his temperature was 101° F. and pulse 72. The urine was febrile. He had, the day before, noted an abundant pharyngeal catarrh, so abundant that he was continually expectorating mucus. He complained of a sore throat and had some conjunctival injection.

*Examination of the throat* showed an erythematous patch of a dark red colour on the right side of the soft palate and uvula, which was in this case unilateral, ceasing abruptly at the middle line. Upon this erythematous patch were seen about half a dozen almost transparent vesicles, about the size of a pin's head, whose base was faintly reddened. More could be seen on that part of the soft palate where there was no erythema. The vesicles were quite firm to touch. There were vesicles also on the posterior pharyngeal wall and also some granulations. There were no adenoids or tonsils to speak of.

There was no anterior nasal coryza. The soft palate was definitely tender to touch, and neuralgia was complained of in the teeth on the right side.

The temperature was down next morning, but there were still headache and "shivering feelings" in the back. In a day or two, the mucous discharge had ceased, but the throat was extremely sore for a week or more and the remissions lasted for a month. The general symptoms subsided in three days, but the vesicles recurred for three weeks or more—i.e., as long as the throat was sore. Even exposure to a cold wind would cause their reappearance after apparent subsidence. Beyond a general nervous debility the case was free from complications. After four to six weeks the hypotonia gradually wore off, with complete recovery.

Bacteriological examinations were kindly made for me by Dr. W. E. Kingdon, of Sheffield University. Cultures from the vesicles were made on haemoglobin media and stained for influenza. Only staphylococci and streptococci were found. True influenza bacilli were obtained by myself earlier from the mucous discharge on the posterior pharyngeal wall, but could only be obtained quite early in the disease.

The above somewhat, but I hope not unduly, detailed description represents a fairly typical case. Whilst the age and sex incidence was not in any way restricted, as a general rule youth and middle-age suffered most.

### Analysis of Syndrome.

Analysis of the syndrome (group of symptoms) falls under four headings, and will be illustrated:—(1) The severity of the initial coryza; (2) the erythema and persistent vesicles in the throat; (3) the sequential neuralgias; (4) the variety of complications.

1. *The severity of the initial coryza.*—In the above quoted case the flow of thin mucus was so severe that it was impossible for the patient to smoke at all, and he was compelled to expectorate large quantities of mucus and saliva. At night he was kept awake by a troublesome hawking. It may be important to note that almost always the cough was relieved by small doses of morphia, this suggesting a nervous origin, in part.

In another case, a male aged 72, who had had cerebral haemorrhage about five years before, was so troubled with coryza that the strain of expectoration brought on epistaxis, which could only be controlled by firm nasal tamponage.

An infant, aged 10 months, was continually salivating and coughing for three days, with much vomiting, showing the excess of mucus had been swallowed.

In another patient continual hawking and expectoration brought on a subconjunctival ecchymosis.

In a pregnant woman, aged 38, the expectoration caused an abdominal muscular rupture.

Such examples are sufficient to demonstrate this very unpleasant symptom.

2. *The erythema and vesicular eruption.*—This complex is largely the *raison d'être* of this paper. In no case examined with a typical influenza syndrome did I fail to find this clinical picture. Also it should be noted that in only one case was there an eruption (and that herpiform, and on a mucous surface, the lips) found elsewhere on the body.

Numbers of patients came up complaining of sore-throat, which they found difficult to get rid of, of 10 days' duration or more, and no other symptoms save slight malaise. Examination of the soft palate, uvula, and posterior pharyngeal wall invariably showed some vesicles about the size of a pin's head, and nearly always accompanied by erythema.

Others came up complaining of facial or orbital neuralgia but no sore-throat. Examination of such cases revealed the same clinical picture; in fact, this throat syndrome one found pathognomonic in this particular epidemic of influenza.

One rather puzzling case of what was apparently influenzal neuralgia, where one expected to find vesicles and erythema,

showed none. After the customary irrelevant excursions it appeared that the patient, aged 22, a woman, had suffered from neuralgia for several years. It was a typical case of neuralgia quinti major, for which she had had many dental operations. Here the exception proved the rule.

Discussion as to the etiology of this condition—namely, the erythema and vesicles—will be given later.

3. *The sequential neuralgias.*—Although almost invariably the neurotoxic effects were sensory, one of seventh nerve palsy was observed. This occurred in a man aged 45. There was no history of otitis media, but insanity had occurred in his brother. The lesion was unilateral and had all the characteristics of the lower motor neurone type. The patient slowly recovered, almost completely. He had a typical vesicular throat, which persisted some three to four weeks. The general disturbance was nil.

In the main, however, the neurotoxic effects fall most heavily upon the sensory nerves, and may be classified thus: A. Pain in the palate and fauces ("sore-throat") due to affection of the palatine and naso-palatine nerves, i.e., fifth root. B. Pharyngeal (pain on swallowing), i.e., ninth root. C. Facial neuralgia, i.e., fifth root. D. Orbital neuralgia, i.e., fifth root. E. Frontal neuralgia, i.e., fifth root. F. Aural neuralgia, with or without vertigo, due to affection of the fifth, seventh, or eighth nerves (the seventh only if exposed).

Severe otalgia, certainly not due to an exposed seventh nerve, except in one case, was quite frequent. It required morphin at times, but rarely preceded a true otitis media of the suppurative variety. Usually it subsided, showing only intense injection of the tympanic membrane. Trifacial neuralgia of a mild type was common, also orbital and frontal neuralgias, both with and without conjunctivitis.

4. *The variety of complications.*—An almost universal feature was nervous debility with a disinclination for food—and for work. Acute prostration was the exception, but one case was thought to be typhoid fever for a short time. Otitis media has been mentioned. Two cases of appendicitis were noted. Herpes of the lips, apart from pneumonia, occurred twice, and there were several cases of persistent sweating on slight exertion. Nervous debility on two occasions merged into melancholia of a mild type. A case of epistaxis in an old man has been mentioned.

It will be convenient at this point to give the actual statistics:—

Cases of undoubted influenza	514
Cases whose throats were examined	456
Percentage of these with typical throat signs	100%
Mortality	0·3%
Percentage of all cases with complications	42·0%
<i>Persistent Neuralgias</i> (i.e., over 48 hours duration).	
Frontal	27·3
Facial	18·2
Orbital	15·7
Aural	13·8
Vertigo	6·9
	100·0

#### Hypotheses as to Mode of Origin of Erythema and Vesicles, with Review of Supposed Mode of Infection.

1. That the vesicles are the accumulated secretion of inflamed mucous glands. A study of the anatomy of the soft palate and surrounding structures reveals large numbers of mucous glands. Whereas these glands no doubt share the toxic effect, the vesicles are quite firm to the touch and resistant, unlike a mere retention-cyst of mucus. Finally the glands are innumerable, but the vesicles few.

2. That the vesicles are part of the clinical picture of aphthous stomatitis. Aphthous stomatitis according to Taylor, is not common in adults. It consists of circular grey patches appearing on the gums about the first dentition, on the tongue, and inside the lips and cheeks. They have the appearance of vesicles which subsequently ulcerate. They are said to consist of a fibrinous exudate beneath the epithelium. They heal in a few days, but may recur. In adults they are far less numerous than in sickly children in whom they are most common. Such a description tallies well with our clinical picture, but for two discrepancies. The erythematous vesicles never appear on the tongue, lips, or cheeks. Moreover, they never ulcerate.

3. That the lesions are caused by an epizootic ("pink eye") transferred to man from certain lower animals. This hypothesis should not be confused with the one which claims that influenza in horses (or other animals) is identical with human influenza. Inoculation experiments have disproved this, for human influenza is not inoculable on animals, or at any rate the human syndrome, as the older

practitioner knows it, is not reproduced. In monkeys some degree of toxicity obtains, but horses are immune. Many writers interpret this as meaning that equine influenza is not communicable to man. Personally I do not see the force of this argument. Until man has been inoculated with equine influenza, who is at liberty to assert that such inoculation will prove abortive? Yet such is the orthodox opinion of to-day. There seems to me no inherent reason why man should not be susceptible to both the equine and human varieties. The history of influenza points to this. Horse-breeders are convinced of its probability. It will, therefore, not be out of place to review two pieces of evidence.

According to Hopkirk, who has studied the history of influenza very carefully, the earliest instance of supposed influenza occurred during the tenth year of the siege of Troy, affecting the Grecian camp. It was very fatal, if it was influenza.

In 1404, Babilonius reports an epizootic of low mortality amongst men.

In 1410-11, in the Paris epidemic, there was an epizootic amongst birds.

In 1562 there was a characteristic outbreak in the British Isles, then called "The acquaintance." "It is a Payne in their heads that have it, and a soreness in their stomaches, with a great cough. It remayneth with some longer, with others shorter tyme, as yt findeth apt bodies. The Queen kept her bedde six dayes. There was no appearance of danger, not manys die except some old folks," so writes Queen Elizabeth's ambassador at the Court of Mary, Queen of Scots.

In 1889-90, in the respiratory type, we note "redness and swelling of pharyngeal mucous membrane, with increased secretion, often followed by laryngitis and conjunctivitis with photophobia. Neuralgia of the fifth nerve was common.

Along with these manifestations which closely resemble, in one respect or another, our syndrome, it was noted that cows and horses suffered in 1733, 1737, 1803, 1831, 1837, and 1915. Also dogs, cats, deer, sheep, swine, poultry, and fish had contemporaneous epizootics on these occasions. It is improbable that on all these occasions when influenza was raging (and can anyone recollect a year when it was not?) that these epizootics were anything to do with the human disease, but they may have been in some instances, and their occurrence is noteworthy.

As regards 1915, concerning the connexion between "pink-eye," mentioned by Goodhart in Allbutt and Rolleston's "System," Mr. C. Sorby Straw, of Streatham, who has owned and bred horses for many years, states that "he believes that 'pink-eye' is really influenza, the 'membranes' become very red. It starts with a chill, they run at the nose, have sore throats, and sometimes end by being broken-winded. Isolation is rigorously carried out." Mr. Straw's son in the Territorial Yeomanry fully believes he contracted laryngitis from "pink-eye" in his horse. Pink-eye was very rife in many camps, so was influenza.

Is there anything in medicine resembling this? Assuredly, we know bovine tuberculosis, or, better, glanders and anthrax. These are epizootics having a slightly different syndrome in man compared with their zoological appearances. It therefore behoves us not lightly to dismiss an influenza case of an atypical nature as impossible of equine origin, although we cannot prove equine origin until some man has been inoculated with "pink-eye."

4. That the lesions are identical with herpes zoster. Herpes zoster is defined by Henry Head as "vesicles on an erythematous base." It will be worth our while to study this affection.

It must not be confused with herpes febrilis. The former rarely recurs, the latter habitually. Zoster is rarely bilateral, febrilis is generally found thus. A definite nerve area is affected in the former, not so in the latter. Central degenerative changes are to be found in herpes zoster, not so in herpes febrilis. The two may coincide. The optimum age-incidence for zoster is 4-13. It tends to occur in epidemics, but they are not easy to trace.

*Acute specific zoster* is analogous to anterior polio-myelitis. Inflammation or haemorrhage of the posterior root ganglion is found. These cells, it is interesting to note, are the morphological equivalents of the anterior horn cells.

In 1896, 1897, and 1898 epidemics occurred in March, May, June, and July, and up to October. Atmospheric conditions and intercurrent disease—e.g., measles, diarrhoea, pulmonary tubercle, arsenical poisoning, dementia paralytica, and other mental diseases—were said to have been etiological factors. Acute lobar pneumonia as a cause is well known.

*Symptomatic zoster* occurs in tabes dorsalis, myelitis, caries and necrosis of ribs, sarcomata, especially those invading ganglia, caries of the spine, and cerebro-spinal

meningitis. It is purely secondary and symptomatic and not of interest in this connexion.

The pathology of these lesions is, however, significant. Marchi's method shows the slow, degenerative changes excellently. The lesions in the central nervous system are haemorrhage into the ganglia in acute cases, with secondary degenerative changes in the posterior roots and their peripheral nerves.

The symptoms are; malaise, a temperature not greater than 100° F., and shooting pains in the affected regions; so severe are they in herpes intercostalis that this has been diagnosed pleurisy or pneumonia. The pyrexia lasts two or three days and the rash only appears on the third or fourth day. Small gangrenous patches on the skin may occur. Hyperesthesia and deficient thermotactic sensation are known as common sequelæ.

Herpes febrilis is but a special name for pneumonic herpes. Herpes of the soft palate is often bilateral. It is not difficult to see many essential differences between these signs and symptoms and those of the syndrome under consideration.

Of the pathology we can compare little. In true human influenza haemorrhagic lesions are well known. Our lesions, possibly similar, were too transient to be so severe as to be mistaken for either typical nervous, old-fashioned "flu," or for typical zoster. Intercurrent disease hardly played any part. The pain at no time was severe and the rash appeared at the outset. Ulceration was never seen, nor was there anaesthesia.

Therefore we may confidently assert that our syndrome was distinct from that of herpes zoster.

Boylan, Heller, Hutchinson, and Hall have reported on pharyngeal herpes, a rare complaint, but none of them give any instances of "contagium vivum" as a cause. Other writers—e.g., H. F. Parsons and Sadler—have referred to cases of epidemic herpes, which were always cutaneous, and therefore irrelevant in this case. Frederick Taylor refers to certain "aberrant vesicles" in herpes. He does not, however, give their site of election, nor discuss their etiology.

Semon, in Allbutt's "System" describes two varieties of "angina herpetica," or herpes pharyngis. The first is comparable to herpes febrilis, the second to herpes zoster. The first has a grave prognosis, the second is painless, afibrile, and recurrent. Wherefore both are irrelevant to us.

5. This leads to consideration of the final suggestion—to wit, that the eruption, although clinically similar to herpes zoster, is, in reality, due to an influenzal intoxication of centripetal diffusion (of tetanus). There was no question but that these were cases of influenza. Their symptoms can be traced all through history, with one exception, yet the throat lesion was invariably present. The *modus operandi*, however, is not clear. Granting that the lesions were herpetic, let us revert to the anatomy of the sensory nerves. Anatomy shows that the sphenopalatine ganglion and its branches connect up with otic, Gasserian, geniculate, and sympathetic ganglia. This implies a possible path for intoxication of their neurones. Neuralgia of the face, teeth, orbit, frontal regions, and throat are conceivably to be explained as toxic neuroses of these ganglia and neurones. Infection is, in the last analysis, intoxication. The process may have started in the palatine branches, and thence spread centripetally, after the fashion of the tetanus toxin. But for all that there were no influenza bacilli to be grown from the vesicles. Even so, they were present in the contiguous sputum, and secondary influenzal lesions generally only contain staphylococci and streptococci. *Faute de mieux*, this hypothesis is the one to which I pin my faith. Nevertheless, I realise that the pathological basis upon which it rests requires further consideration. I am prepared to go further and admit that the hypothesis is largely the product of induction, nevertheless I believe that the train of reason which led to it will bear the test of logic. The inductive method is copied from good sources. It led Charles Darwin to the theory of evolution.

#### *Conclusions.*

The influenza toxin spreads centripetally along the sensory nerve tracts, expending itself on the first footholds—i.e., pharyngeal mucosa and its substructures—and thence passes to the palatine nerves. The effect of the virus is inflammatory; on a mucous surface it causes a vesicular eruption ("vesicular neuritis"), whilst deeper down it causes similar inflammatory changes, giving rise to pain.

The virus spreads far into the central nervous system, even poisoning the vagal or sympathetic nerves. Tachycardia and bradycardia are well-known sequelæ. The cerebrum shows

the aftermath of influenza in a varied and sometimes to a sinister degree. The epidemic of spring, 1915, in London conceivably had an equine origin, not conversely, for human influenza cannot affect horses. That the syndrome occurred elsewhere is not unlikely. Military cases seen as late as February, 1917, without exception show "vesicular neuritis."

The theory of centripetal diffusion of the toxin via the neurones seems borne out by the rarity of influenzal septicemia as compared with the frequency of neuralgia, &c., in influenza. It is very rare to find Pfeiffer's bacillus late in the disease and rarer still to find it in late complications. It is not even agreed that Pfeiffer's bacillus is the cause of influenza, but, assuming that it is, the diffusion of the toxin which has a partiality for the neurones mentioned is, to my mind, better explained by the theory of centripetal nerve diffusion (of tetanus) than it is by the theory of hemic diffusion.

No one is better aware than I am, however, that the pathological depths of this subject require far greater exploration before the theories herein propounded may become facts. Any information on the subject will therefore be very welcome.

## THE NERVOUS FACTOR IN RELATION TO OPHTHALMIC CONDITIONS.

BY T. E. HARWOOD, B.A. OXON., M.B., CH.B. EDIN.,  
RESIDENT OPHTHALMIC OFFICER, THE KING GEORGE HOSPITAL, S.E.

THE war is the greatest nervous strain the world has ever known and has brought the nervous element in disease into prominence again. It is impossible to remain long in a large military hospital at the present time without seeing the essential similarity between the effects of fatigue, shock, and traumatism, and the results of intoxications, glandular deficiencies, dietetic errors, and psychic influences. The fact that a patient is cured by the exhibition of thyroid extract, or by a colectomy, or by judicious dieting, does not prove that the cause of his condition was either his thyroid, his colon, or his cook. What one wants to know is why his glandular secretion is no longer adequate, why his intestinal contents have become poisonous to him, and why he cannot eat the good square meals he used to enjoy.

Sir James Goodhart said many years ago that there are only two kinds of indigestion: that due to over-eating and over-drinking and that due to deficient nervous energy. The alimentary canal of a patient whose nervous energy is inadequate may show abnormalities of peristalsis, absorption, and secretion, all or any of which may be increased or diminished. Whether the actual discharge of secretion is due to a nervous or to a chemical stimulus, the trophic condition of the gland, and therefore the production of the secretion is under the control of the nervous system. There are, then, two ways of treating indigestion due to defective nervous energy, the one to order an easily digestible diet, the other to increase the available nervous energy. So also with the ductless glands, we may either exhibit what we think to be defective, or we may try to set more energy free with a view to restoring the natural harmony. Similar arguments apply to almost any part of the body, hence the therapeutic value of rest.

The total amount of nervous energy varies greatly in different persons, and this total amount may be so far reduced as to make the ordinary duties of life inadvisable or impossible by four different causes: (1) any exhausting stimulus or succession of stimuli; (2) poisons or toxins; (3) inadequate nourishment or loss of blood; (4) psychic influences. The existence of one cause favours the action of another. A man who is

suffering from a serious head injury is, *ceteris paribus*, more likely than another who is not to be infected by toxins, he will not stand a serious hemorrhage so well, and his recovery will be retarded by any great grief or anxiety. Similarly, an alcoholic is more liable than a temperate man to fall a victim to his own pneumococci after a chill, and not the least important factors in his treatment are rest, suitable nourishment, and freedom from worry. Such a condition of lowered nervous energy is in reality always a general one, but is apt to show itself more particularly in certain organs, either because they are points of least resistance or because the toxins at work have a special affinity for them. The presence of pyrexia also depends largely upon the predominance and nature of the toxic element. The existence of a gross organic lesion, such as mitral stenosis, is in itself a great tax upon the available nervous energy, and if it leads ultimately to death it does so because from some such causes as those mentioned above the nervous energy is no longer adequate to meet both this and the ordinary calls of the body.

In the present state of our knowledge the eyes are almost the only part of the nervous system which admit of constant direct mechanical assistance. Very few eyes are of perfect shape, and practically no pair of eyes. The imperfections are as far as possible corrected by neuro-muscular action, and, as it is only rarely that both eyes are symmetrical, the effort needed is usually different for each eye. Not infrequently also the balance of the external ocular muscles is not exact, so that further effort may be necessary to keep the visual axes parallel. All this muscular effort is constantly maintained except during sleep, and uses up a certain proportion of the total nervous energy, small indeed and probably inappreciable in health and youth, but far greater and more important in ill-health and as years advance. Indeed, in acute illness, when the patient is confined to bed, the ocular muscles are almost the only muscles not essential to life which are in comparatively constant use. That a patient should have trouble with his eyes during or after such an illness usually occasions but little surprise either to himself or to his physician, and they both expect them to improve with the general health. Much can be learnt as to the nature of morbid conditions by applying the converse of this and seeing what effect is produced upon these conditions by removing the ocular element as far as it is possible to do so, and so relieving the nervous energy of a certain amount of the work imposed upon it. The methods available for this purpose are: (1) covering or shading one or both eyes; (2) the use of cycloplegics; (3) the accurate correction of refractive errors; (4) the employment of prisms; (5) the use of tinted or Crookes's lenses.

In acute illness the patient is apt to protect himself by keeping his eyes shut and avoiding bright lights. When he is definitely complaining of one eye more than the other his general condition will almost always improve to a striking extent if the eye complained of is covered by a light comfortable shade. This should always be borne in mind in obscure conditions, such as intractable vomiting. Still further help may often be given by atropising both eyes, after excluding all possibility of glaucoma, and shading the one complained of. When covering one eye has given great relief, trouble may be expected when the shade is abandoned, and the patient should never be got up till he can use both eyes together again. Tinted glasses might be used with advantage in acute conditions more than they are, and when a patient has received benefit in comparative health from glasses correcting his refractive errors it is illogical for him to give them up entirely in severe illness. Shading or even bandaging both eyes may be of great value when an invalid has to be taken on a journey. In an acute illness, whatever its nature, the eyes should always be definitely inquired about with a view to relieving general symptoms. It is obvious that the methods referred to act, partly by diminishing peripheral stimuli and partly by lessening the calls on the nervous energy.

But it is from subacute and chronic conditions, in which time is not of so much importance and there is not so much confusion between *post* and *propter*, that one can learn most. Dark glasses may be of use in many such cases, but if they are used the tints should be reduced at rapid intervals or the patient may find it very hard to give them up. Covering one eye will be almost certain to improve the general condition if the eye is painful or cataractous, or

if there is any considerable anisometropia or heterophoria. Here, again, it is necessary to use common-sense and not to allow the patient to do all sorts of things because after a few days he feels much better, and so throw another form of strain upon the nervous system and only rob Peter to pay Paul.

The accurate correction of refractive errors is a most important method of studying nervous energy. The patient should be chosen because his symptoms are intractable and uncanny, because he does not convalesce in the orthodox way, because he gives a history of rheumatism, "influenza," appendicitis, &c., rather than because he is complaining of his eyes. Every system should be inquired into, and it is advisable, and makes a useful exercise, to elicit the information required without making any reference to the eyes. One soon becomes accustomed to the different manifestations of lessened nervous energy in the different systems, and it is usually easy to distinguish the malingerer from the genuine sufferer. One is playing with edged tools all the time, and has no right to order glasses as medical treatment unless the patient can be kept under observation until the accuracy of the correction has been proved. It may be possible to prescribe accurately at the first attempt, but I can only say that, after between four and five years' work at the subject from this point of view, I become more and more convinced day by day of the difficulties that have to be faced. One is trying to fit the rigid to the less rigid, and it is no easy task. The only test of accuracy is a decided improvement in the patient's general condition, obvious to himself and to others. The relief of headache is no test, and headache at least has the advantage of calling attention to the eyes, while other symptoms that may be substituted for it are far more subtle and therefore more dangerous. The more the nervous energy has been lowered the more obvious will be the patient's improvement, and the more quickly it will pass off if the correction is only partial.

A large stock of lenses should be kept, and the correction changed every few days until the greatest possible accuracy has been obtained, so that a minimum, and as far as possible equal, amount of work is left for each eye to do without changing its nature. The sphere is usually a greater difficulty than the cylinder, and the slightest over-correction of either element leads to the patient having ultimately to deal with a new unnatural error. When the real correction is R. + 0.375 C., L. + 0.125 S., + 0.25 C. and + 0.25 C. is ordered for each eye, there will almost certainly be great temporary improvement, but the remainders—viz., R. + 0.125 C., L. + 0.125 S., may ultimately prove at least as much trouble to the patient as the original condition. The smaller the error the easier it is to obtain accuracy; small degrees of myopic astigmatism are by far the easiest to deal with, and give most satisfactory results. A cycloplegic is almost always necessary, and if atropine is used the patient's comfort is often greatly increased by keeping one eye covered by a shade or opaque disc. If it is necessary for him to continue at work he can have the atropine in one eye at a time and keep the atropised eye covered. In difficult mixed or compound cases it may be advisable to get the worse eye right before starting on the other. Though good results are not probable unless the patient can be made to read at least 6/6, one should not be content with any artificial standard, but rather with the maximum acuity it is possible to get out of each eye.

Anyone who will try conscientiously to correct refractive errors on some such lines as these will find that he can do a great deal of good, and that he has opened up a fascinating method of studying the nature of morbid conditions.

---

IN view of the value of the rabbit as food, the Vice-Chancellor of the University of London has given instructions that it shall not be used in practical examinations in zoology for science students or in general biology for medical students during the period of the war.

**THE CHARD TOWN COUNCIL. THE WATER-SUPPLY, AND COMPENSATION FOR ENTERIC FEVER.**—At the last meeting of the Chard town council the subject of the compensation for persons who had contracted enteric fever and who had claimed out-of-pocket expenses from the council came under discussion. The matter has been previously mentioned in THE LANCET. The finance committee, to whom the whole question had been referred, reported that they could not recommend the council to accept any responsibility or admit any claim.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### A CALCIFIED FIBROID CAUSING COMPLETE AXIAL ROTATION OF THE UTERUS.

BY C. HUBERT ROBERTS, M.D. LOND., F.R.C.S. ENG.

THE patient was admitted to the Samaritan Hospital for Women. She was aged 55, married, no pregnancies. The periods had ceased for ten years, previous to which they had been very profuse.

The patient stated that she knew she had a tumour in the abdomen "for many years," but that it had given her very little trouble. About three months before admission she began to suffer with acute attacks of abdominal pain, which of late had been very severe and accompanied with cramps and sickness. Her general condition was good. On examination a large hard swelling could be easily felt in the abdomen, reaching to the level of the umbilicus, more marked on the left side than the right. It was very mobile and could be freely pushed about the abdomen. On vaginal examination there was a small atrophic cervix; movements of the abdominal mass communicated themselves to the cervix. The fundus could not be determined. The diagnosis was made of a calcified fibroid, ovarian dermoid, or ovarian fibroma. There was no free fluid.

On Nov. 16th last the tumour was removed by abdominal section. It was easily lifted out of the abdominal cavity, and was found to be densely hard and very heavy. The remarkable feature of the tumour was its pedicle, 8½ inches long, the thickness of two fingers, and consisted of an enormously elongated senile uterus, which at the level of the supravaginal cervix had undergone an acute axial twist, 2½ times, the twist being from left to right forwards. The appendages were included firmly in the twist. The torsion was easily undone, and the tumour simply amputated from the fundus uteri, to which it was attached by a pedicle 1½ inches wide. The vessels below the twist were deeply engorged, but there were no adhesions anywhere and no free fluid. The senile uterus and appendages were left *in situ*. The patient recovered completely, the temperature being normal throughout her stay in hospital.

The tumour was a well-marked example of complete calcareous degeneration of a fibroid. When fresh it weighed 4½ lb. It was so hard that it took a considerable time to cut through, and spoiled two saws in the process.

The importance of the specimen is that it caused axial rotation of the uterus. Axial rotation of the pedicle of a stalked fibroid is not uncommon, and may lead to acute degeneration of the tumour, but complete torsion of the uterus itself is very rare. I have not met with a case in my own practice before. Most of the cases reported of axial rotation of the uterus by a fibroid have been only partial—i.e., say half a twist—possibly leading to acute abdominal pain, accumulation of blood or pus in the uterus, or necrosis of the tumour.

In this case the twist was 2½ times, but as the uterus was senile and the pedicle very thin from long traction this amount of twisting was easily possible, in the same way as it sometimes occurs in pedunculated ovarian cysts.

Welbeck-street, W.

#### "THYROID STONE."

BY VERNON PENNELL, M.A., M.B., B.C. CANTAB.,  
FELLOW OF PEMBROKE COLLEGE, CAMBRIDGE.

THE following case may be of interest, owing to its comparative rarity.

The patient, a man aged 45, sought advice for aphonia which had lasted for three months, and which he thought might have been due to excessive smoking. On laryngoscopic examination, however, it was seen that the left vocal cord was completely paralysed and immobile. The heart, lungs, and central nervous system showed no lesion, nor was there any cervical gland enlargement. There was a small, hard lump on the left side of the neck, situated in the position occupied by the left lobe of the thyroid.

It moved upwards and downwards on swallowing and did not appear to be very fixed in its attachments, except when attempting lateral movements. In size it was about that of a small walnut, and was slightly tender on deep palpation. A diagnosis of early carcinoma of the thyroid with infiltration of the left recurrent laryngeal nerve was made, and operation recommended. The thyroid was exposed by a transverse incision at the root of the neck and the left lobe identified. On delivering the upper pole forwards, a craggy mass of rock-like consistency was found, rather larger than had been expected from external palpation, in the position normally occupied by the superior parathyroid. It was tightly wedged between the thyroid gland and the oesophagus and vertebral column, and pressed on the recurrent nerve of that side. As part of the left lobe presented several small cysts, it was deemed advisable to perform hemithyroidectomy. The wound healed by first intention and the patient made an uninterrupted recovery, regaining full vocal power after three days.

The growth proved to be a completely calcified adenoma with only the thinnest of capsules stretched over it. It was quite easily detached from the remains of thyroid tissue of that side. As no sign of a superior parathyroid was found after careful examination it is conceivable that this mass was parathyroid rather than thyroid in origin. The diagnosis would almost certainly have been greatly assisted by a skiagram, but this was unfortunately omitted and an unnecessarily gloomy prognosis given.

Pembroke College, Cambridge.

#### AN OBSCURE CASE OF PSOAS ABSCESS.

BY EVELYN A. CONSTABLE, M.B., B.S. DURH.,  
SURGICAL REGISTRAR, LONDON TEMPERANCE HOSPITAL.

THE case on admission presented difficulties of diagnosis, and is for that reason worth recording.

The patient, a female, aged 41 years, married, was sent in, on Dec. 16th, 1916, by Mr. F. Greaves, to the London Temperance Hospital, under the care of Mr. J. McClure, complaining of pain in the right loin and vomiting. Three weeks before admission there was gradual onset of "aching pain" in the right side of the abdomen, accompanied by vomiting, which had occurred twice or thrice daily for the last two weeks. Bowels opened daily (only took aperient once). Menstruation was usually very regular; the last period was two weeks over time, so patient ascribed her symptoms as probably due to pregnancy. She had never had a similar attack before. There was nothing in the past history bearing on the case. Condition on admission: Tongue dry, red, and ridged. Some gingivitis and dental caries. Appetite usually very good. Urine neutral, specific gravity 1018; no albumin or sugar. Spine: no tenderness on percussion or other abnormality detected after careful examination. Locally a hard, oval-shaped mass of the size of a small cocoanut extended from just below and to the right of the umbilicus to the right costal margin; it was slightly movable at the inner pole but appeared fixed at the upper and outer one. It did not move on respiration. Per vagina the cervix was soft and lacerated, "erosion" present; uterus freely movable. Blood count by the pathologist, Dr. H. H. Sanguineti: Hb 65 per cent.; erythrocytes 5,560,000, leucocytes 25,500 per c.mm. Differential count, per cent.: Polymorphonuclears, 89; lymphocytes, 10; transitional, 1. Diagnosis: ? Malignant disease of ascending colon; ? kidney tumour; ? appendix abscess.

Laparotomy by Mr. McClure on Dec. 31st. A vertical incision, 5 inches long, was made over the tumour in right hypochondrium. The "tumour" turned out to be a normal right kidney, pushed forward by a large psoas abscess. The latter was incised below and posterior to the lower pole of the kidney, and about 1½ pints of green homogeneous pus were evacuated, evidently coming from the spine. The cavity was irrigated with a flushing curette. The posterior peritoneal layer was then approximated by interrupted sutures and the anterior abdominal wall closed in layers. No drainage. The vermiform appendix and gall-bladder were examined and appeared normal. The skin and subcutaneous tissues, unfortunately, broke down, but afterwards did well on Dakin's hypochlorite dressings, and patient left hospital on Jan. 29th, 1917, with only a very small superficial wound.

X ray skiagram, taken by Dr. J. H. Rhodes after the operation, showed some erosion of the right side of the body of the second lumbar vertebra.

A somewhat similar case, I am informed, occurred in this hospital about 16 years ago. I am indebted to Mr. McClure for permission to publish the above notes.

West Green, N.

## Medical Societies.

### ROYAL SOCIETY OF MEDICINE.

#### SECTION OF ELECTRO-THERAPEUTICS.

##### *The Origin of Electric Currents led off from the Human Body.*

AN ordinary meeting of this section was held on March 16th, Dr. G. HARRISON ORTON, the President, being in the chair.

Professor W. M. BAYLISS read a paper entitled "The Origin of the Electric Currents led off from the Human Body." It was concerned with an examination of the book on the subject of "Electric Pathology" written by Mr. Baines. The whole of this theory, and the practice founded upon it, depended on what Mr. Baines termed "nerve leaks," these leaks being detected by the use of silver electrodes and a high-resistance, very sensitive galvanometer. The human body was a very heterogeneous system, the solids of which in a dry state were non-conductors of electricity, but when soaked with salt solutions became conductors. So that the human body, as a whole, was a conductor, of a kind, but not at all comparable to that of a telegraph cable. It was not merely the salts in the solutions which conducted the electricity; it was the ions of the salts, from which they were dissociated when dissolved in water. The dissolving in water split the salt up into two separate parts, each of which had an opposite electrical charge, though when united together they were neutral. Though that seemed obvious, it was not the view taken by Mr. Baines in his book, for he said: "It is now held that this view is incorrect, and that when a salt is dissolved in water its constituent molecules undergo, to a greater or less extent, atomic as well as molecular dissociation, so that a portion of the electrons become free and are diffused throughout the water as ions." Mr. Baines spoke as though electrons and ions were identical. It was one of the chief errors underlying the thesis. This was confirmed in the glossary, for ions were defined as "free electrons in gases, fluids or solids." There was no proof that atomic disintegration took place when salt was dissolved in water. The sodium ion was non-volatile; and it was an electric charge united to a sodium atom. When that reached the skin it could not get further; it could not have escaped to the air, though if there were free electrons conceivably they might escape, if there were a sufficiently high potential. Mr. Baines assumed the existence of "neuro-electricity"—namely, a stream of free electrons passing down the nerves. It was safe to assume that the body, though full of ions, had no free electrons, so that anything which demanded the presence of free electrons could not take place. The second point was, that silver electrodes were used to lead off these currents. It was impossible to get two pieces of the same metal so nearly alike that when immersed in salt solution there would not be sufficient difference of potential between them to deflect the sensitive galvanometer which Mr. Baines used. He (the speaker) had failed to get two electrodes so similar that this did not happen, though they were cut from the same bar. A difference of only 6/1000ths of a volt caused such deflection. Mr. Baines ought certainly to have tested his electrodes first. What would be the effect of placing these electrodes on different portions of the skin? Dry skin ordinarily possessed a high resistance, but when the skin was moistened its resistance was lowered, and the difference between the readings from the two constituted one of Mr. Baines's "nerve leaks." It was found that the electrodes were unequal by immersing them in salt solution, and therefore it was known that the source of the current in that case must be at the surface of the electrodes. Since one was more positive than the other, if they were changed round the current was reversed, but it did not always happen when one reversed the connexions with the galvanometer. This Mr. Baines insisted upon as a proof of the occurrence of nerve leaks. The reversal when changing from one hand to the other showed there must be a source in the body itself. Another proof that there might be a source of electromotive force in the skin itself was by using not metallic electrodes, but by employing what physiologists called non-polarisable electrodes, which could easily be made equi-potential, so that the electrodes themselves gave rise to no current at all; hence anything observed was due to something

in the skin. But Mr. Baines would have nothing to do with non-polarisable electrodes, though the reasons he gave were very difficult to understand. Still, he said that was the reason no advance had been made in electro-physiology since 1877. The answer to that was, that one could not get a true representation of electrical changes in a structure like the human body unless one used electrodes which were not polarisable. What was the source of electromotive force in the skin? Clearly, the activity of the sweat glands was associated with this change, and one could not be sure of the degree of activity of these glands in any part where one led off. This accounted for Mr. Baines's second kind of nerve leak. It added itself on to the first one. Why were these "nerve leaks" more easily detected in cases of shell shock and other neurasthenic conditions? A Russian physiologist found that various mental states were associated with various localised activities of sweat glands. The changes in the electromotive activity of glands and other tissues in the body were explained most readily by the presence of a membrane which allowed one kind of ions to pass through, but did not allow other kinds to do so; it might be due to its own electrical charge or to the size of the pores. But they could not leave the neighbourhood of the membrane because of the influence of the oppositely charged ion inside the membrane. The second kind of nerve leak was more genuine than the first, but it had nothing to do with the escape of neuro-electricity. With regard to the question of static charges that was a difficult question, as was also that of inductive capacity. Mr. Baines evidently meant by a static charge what happened when one stood on an insulated stool and charged the body from a source of static electricity. But that did not influence any process going on inside; he had tested the point with a galvanometer. The static capacity was of no importance in the physiology of the human organism. The inductive capacity puzzled him a great deal, for he did not know what was to prove that the body had an inductive capacity. "Neural electricity" Baines defined as "a form of energy resembling, but not identical with, electricity"; but in another place he spoke of neural electricity as circulating in the coils of the galvanometer. If it were ordinary electricity, the tying of the cut ends of a nerve and surrounding it with an insulator would result in its conduction as if it were not cut. But everyone knew such was not the case, and no muscular contraction followed. Most probably it was associated with some kind of polarisation of membranes—i.e., movement of ions. As to the practical application based upon these theories, if the conditions described were due to leakage of nerve energy, and that energy was a form of electricity, applying an insulator would cure the case. The author included in conditions favouring leakage inflammatory states such as pneumonia, the reason being that inflammatory cells were not properly supplied with nerve energy. Baines said that if any cell or group of cells was isolated from nervous influence and control the whole of its activities ceased in a short time. But was it true that cells and tissues would not behave normally unless they were in association with the nervous system and receiving a perpetual supply of nerve energy? Clara Jacobson, in America, tested the rate at which wounds made on opposite legs of an animal healed, when the nerve-supply to one was cut and that to the other remained intact; and she found no difference in the rate. The whole theory of nerve energy rested on the erroneous assumption that energy was present in the nervous system to only a limited extent; so that energy used in one way left less for other purposes. Baines used "dielectric oil" to stop the nerve leak, and this was found to be fairly good quality liquid paraffin, which had been dried, probably by the application of heat to it. It was claimed that the process employed conferred upon the paraffin properties which could not be detected by any chemical or physical means. The obvious answer to that was, that if the properties could not be detected it was of no use making the statement that they were there. The great penetrating power of this dielectric oil on the skin—it was said, when applied for pneumonia, to go right through the chest and appear on the bedclothes at the back—rested upon very inadequate evidence. To test this penetration Professor Bayliss allowed a pad to soak on the skin and tested the electrical resistance between the part soaked with paraffin and another part, but during three hours there was no change of resistance. To

state that the temperature of a case of pneumonia fell after its application meant nothing, for a fall of temperature in that disease was often quite spontaneous. Professor Bayliss summarised the conclusions he had reached on the matter as follows. The currents led off from various parts of the body by metallic electrodes were due to the inequality of the electrodes and to differences in the activity of the skin glands. Neither static charges nor induction played a part in the phenomena. "Nerve leaks" were merely places at which the skin was moist. The view that neuro-electricity is generated in the brain, and escaped from nerves owing to a breakdown of insulation was devoid of evidence and contrary to our knowledge of physiological processes.

In the ensuing discussion Dr. AGNES SAVILL said she had had very little experience with the "dielectric oil," but it had been good. She quoted the case of a lady who had eczema of both feet, to an equal degree in each, and the foot on which the dielectric oil was used healed quicker and was less irritating in the process than was its fellow.

Captain HERMANAN-JOHNSON spoke of the value of the method in diagnosis. He took two cases to be tested by it, the natures of which were unknown to Dr. Hill Wilson, who saw them for the purposes of the test. One, a case of chronic dysentery, showed a violent deflection of the mirror when the mid-dorsal region of the spine was reached. The other was diagnosed as having something wrong with the pelvic organs; it was a case of dysmenorrhoea followed by amenorrhoea. He did not think the question of unequal moisture of skin played a part, because the skin was previously rubbed with a rough dry towel.

A number of questions were asked, to which Professor BAYLISS replied.

#### SECTION OF OBSTETRICS AND GYNECOLOGY.

*Exhibition of Specimens.—Total or Sub-total Hysterectomy for Removal of Myomata.—Curious Degeneration of Cervical Tumour.*

A MEETING of this section was held on March 1st, Dr. G. BLACKER, the President, being in the chair.

Dr. CUTHBERT LOCKTER showed: (1) Specimens illustrating Simultaneous Pregnancy in each Fallopian Tube; and (2) a Metastatic Glioma (Neuro-epithelioma) of the Ovary in a child of 3 years.

Dr. HERBERT SPENCER read: 1. A paper on two cases of Supravaginal Amputation for Sarcoma Mistaken for Myoma. The patients recovered, but the disease recurred. The operations were performed 17 and 20 years ago. It was these two mistakes in diagnosis which led him to study the relative advantages of amputation and total hysterectomy, and to decide very strongly in favour of the total operation. 2. A paper on four cases of Undiagnosed Cancer of the Cervix in 200 Total Hysterectomies for Myoma. All the cases were squamous carcinoma; two were very early and high up in the cervical canal; the others more extensive, but out of reach on account of the presence of pelvic tumours. The first died from heart disease within a year of the operation; the second remained well after six years; the third remained well for five years, but died of recurrence after nearly six years; the fourth recurred within a few months. He appealed to the advocates of supravaginal amputation for a comparative record of 100 or 200 cases followed up and examined for five years after operation. He had not himself performed this operation for the last 16 years.—The PRESIDENT said that the question whether total or sub-total hysterectomy was the best operation for the removal of fibro-myomata of the uterus was one of great importance. With sarcomatous degeneration of such a tumour, however, the question was not so important as it was when a carcinoma developed in a fibroid uterus. So far as he knew, the cases recorded in the literature showed that the chances of recurrence were equally great, whether the cervix was retained or not. He asked if the recurrence had involved the cervix in the two cases recorded by Dr. Spencer.—Dr. H. R. ANDREWS stated that he had at one time performed panhysterectomy as a routine operation for fibroids, but for the last 10 years had removed the whole cervix only in cases in which laceration and eversion of the cervix made it probable that there would be persistent discharge if the whole cervix was not removed. His practice was to scoop out most of the cervix, and in doing this he had only once found unexpected carcinoma,

although he had removed many uteri which contained both fibroids and carcinoma. During the last eight years 761 hysterectomies for fibroids, chiefly subtotal, had been performed at the London Hospital. Dr. Andrews and the late Dr. R. D. Maxwell had been for many years on the look-out for carcinoma occurring in the cervix that had been left behind, but no such case had been seen at the London Hospital.—Dr. T. W. EDEN remarked that two of Dr. Spencer's cases, although in a very early stage of the disease, died from recurrence, and it could not be doubted that an extended hysterectomy (Wertheim) would have given them a better chance. To be consistent, Dr. Spencer should have advocated Wertheim's operation instead of panhysterectomy.—Mr. J. D. MALCOLM said that he had for many years removed the whole uterus in operating for fibromyoma after seeing two cases in which he had attributed septic trouble to a spread of infection from the cervix uteri.—Mr. T. G. STEVENS said that in his opinion the appearances seen in the microscopic sections of Dr. Spencer's first two cases were those of erosion of the cervix.—Dr. SPENCER replied.

Dr. C. HUBERT ROBERTS read a short paper on a Curious Degeneration of a Cervical Tumour removed from a patient aged 35 years. He also showed a specimen of a Calcified Fibroid causing complete axial rotation of the uterus; an account of the case is published on p. 454 this week.

#### Reviews and Notices of Books.

*Syphilis and the Nervous System.* By Dr. MAX NONNE. Translated by CHARLES R. BALL. Second American edition. London and Philadelphia: J. B. Lippincott Company. 1916. Pp. 450. Price 18s. net.—This edition of Dr. Nonne's classical work is based on the third German edition of 1915. The six years which had elapsed between the appearance of the second and third German editions have seen the *Spirocheta pallida* given its proper place in the causation of general paresis as well as of tabes, and the portion of the book dealing with this subject has therefore largely been rewritten. But the general arrangement based on clinical lines has been retained and constitute the value of the work as a useful guide to practice. Some minor blemishes remain unaltered from the last edition and may probably be due to the great distance by which author and translator are separated. The appearance of a new edition is timely.

*A Historical Sketch of the General Infirmary at Leeds.* Leeds: Richard Jackson.—This little book tells the story of the General Infirmary, Leeds, from its inception in 1767. At this time a house was rented at £16 per annum, two physicians and four surgeons were appointed, as well as a matron and nurse at the princely salaries of £10 and £5 a year respectively. Among the first surgeons to the infirmary was a pupil of John Hunter, Mr. William Hey, F.R.S., to whom the honour of founding the institution is in large part due. A century later, that is, between 1869 and 1901, the infirmary was rebuilt at a cost in land and buildings of approaching £230,000, and a further extension was carried out as a memorial to the late King Edward at the added cost of £150,000. The number of in-patients rose from 76 in 1768 to 6071 in 1900 and to 9703 in 1915, and these figures show better than words the remarkable growth in a century and a half of an institution with which have been associated the names of many well-known physicians and surgeons. The story, which is illustrated with portraits of the founder and others associated with the infirmary, has been compiled from annual reports and makes no pretence to completeness. It gives, nevertheless, a worthy account of a great institution.

*Pharmacology and Therapeutics.* By HORATIO C. WOOD. Second edition. London and Philadelphia: J. B. Lippincott Company. 1916. Pp. 455. Price 18s. net.—The new edition of this text-book has been held back to await the appearance of the new U.S. Pharmacopoeia, which has necessitated a complete revision of its contents. The articles on such products as veronal, pituitary extract, and salvarsan have been rewritten, and a number of substances such as bromural, picrotoxin, and thiosinamin considered for the first time. The author welcomes the adoption of the term mil in place of c.c. for the thousandth part of the litre. The book will be of interest to all whose reading takes them outside the statutory requirements.

*Representative Procedures in Quantitative Chemical Analysis.* By FRANK AUSTIN GOOCH. New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Limited. 1916. Pp. 262. Price 8s. 6d. net.—We have presented here by a well-known authority on the subject a valuable series of analytical methods applied to inorganic substances; the particulars of procedure described give trustworthy and accurate results in the light of the latest experience. We are glad to note the author's appreciation of "the beauty and accuracy" of the iodometric processes, and he has given a much more extended treatment of this section of the subject than is usually the case in analytical text-books. The clear and careful directions set out mark the experienced hand at analytical work. Useful ground is covered in regard to procedures in both gravimetric and volumetric analysis, but in the latter section we find no reference made to the convenient reduction methods in which titanium salts are used as reducing agents.

*The Motor-car.* By T. O. A. LAWTON and R. J. HARVEY GIBSON. London: Edward Arnold. 1917. Pp. 87. Price 1s.—This is a simple little primer that takes the intending driver by the hand, so to speak, like "Little Henry's Guide to French," and leads him step by step to knowledge and, if coupled with practical instruction, to the confidence that should justify him in taking the road unaided. It is all very elementary. Whether such aids are more easy to understand than the usual text-books is a question.

*Organotherapy Products.* Issued from the Bacteriological Research Laboratories of Evans Sons Lescher and Webb, Limited, Higher Runcorn, Cheshire. February, 1917. Pp. 60.—With this catalogue and price-list of their organo-therapeutic products the manufacturers have incorporated 10 pages of text describing the principles of hormone therapy and 40 pages more on the preparation and uses of organ extracts. The notes are well printed and well arranged, and will afford the busy practitioner useful information on the therapeutic material available in this still somewhat obscure region of medicine.

#### JOURNALS.

*The Philippine Journal of Science, Section B, Tropical Medicine.* Vol. XI, No. 3.—Dr. Edward S. Ruth writes on the development of twins and other polyembryos with special reference to four sets of duck twins. After reviewing the work done already on the subject, this observer, in a series of approximately 500 duck eggs that were incubated for embryological material, found four sets of twins. One set had developed to the 3-somite stage and the other three sets respectively to the 9-, 11-, and 12-somite stage. In only one set were the embryos completely separated from each other; in the others the embryos were joined along their lateral sides and would in all probability have developed into joined twins. The underlying causes involved in the formation of twins and other polyembryos are obscure. It has, however, been definitely shown that in some anamniotes twins, triplets, quadruplets, &c., can be produced by mechanical and chemical changes. These definite results have been obtained by altering the environment by external agents. If the intrinsic factors be considered, Dr. Ruth thinks that little imagination is needed to conceive of distorted embryos, twins, &c., as being due to a faulty metabolism or to some physical law that is so wrapt up in physio-chemical processes that it is still impossible to solve the mystery. This paper is illustrated by three plates.—The influence of fresh and autoclaved cow's milk on the development of neuritis in animals is discussed in an article furnished jointly by Dr. R. B. Gibson and Dr. Isabelo Concepcion. They were led to make experiments by the fact that the use of "canned whole cow's milk" for feeding infants is rapidly increasing in the Philippine Islands, and they sought to obtain information as to whether or not the antineuritic vitamines of milk are destroyed by heating. It would appear from previous experiments that antineuritic properties, if present in milk, exist only in very small amounts, and in none of the observations already reported has milk prevented the development of neuritis. Accordingly, the authors directed their attention to ascertaining by feeding experiments whether or not antineuritic substances were present in milk, and to what extent these would be affected by autoclaving the milk for two hours at 125° C. The first observations were made

on fowls, but subsequently on young dogs and pigs. The results on the latter animals indicated that autoclaving the milk did not affect appreciably either the growth promoting principles in it or the nutritive value of the caseinogen. The antineuritic vitamine is present in milk in slight amount, and continued feeding of dogs and pigs with either fresh or autoclaved milk, without suitable additions to the diet, induced certain beri-beri-like symptoms, such as degeneration of the peripheral nerves, persistent oedema, and aphonia. There was no evidence that autoclaving milk for two hours at 125° C. affected in any way its nutritive value. The authors remark, in conclusion, that at the best the antineuritic powers of the milk are so slight that in infant feeding the diet should be extended as soon as possible. They further suggest that the young of healthy mothers probably come into the world with a reserve supply of the vitamine substances sufficient to tide them over nutritively until the time when, under natural conditions of life, they would begin to eat other food. This article is illustrated by two plates.—The remaining contribution to this number of the *Journal* deals with the blood pressure picture of the Filipinos, and is supplied jointly by Dr. Isabelo Concepcion and Dr. Emilio Bulato. Little work on blood pressure has previously been done in the Philippine Islands. The authors give details of the observations they made by the graphic method with the Erlanger sphygmomanometer on 717 persons whose average age was 28·5 years. Their findings showed that the systolic pressures of Filipinos were very much lower than those of Americans. The average pulse pressure was 36·4 millimetres in males and 32·6 in females; there was a general rise of systolic, diastolic, and pulse pressure with age. For a given age the systolic pressure is more variable than the diastolic. The pulse pressure does not differ very much between the different ages, and persons with blood pressure below 20 or above 50 millimetres are probably abnormal. Hypertension is not a necessary accompaniment of old age. The pulse-rate of Filipinos averaged a few beats above the usual standard of 72 per minute. Examination of 65 persons addicted to the opium habit showed that in all of them the blood pressure averages were lower than normal.

*The British Journal of Ophthalmology.* Vol. I., Nos. 2 and 3 (February and March).—These numbers of the new journal contain several interesting original papers. Colonel R. H. Elliot publishes a paper read at the Oxford Ophthalmological Congress on Some Eccentricities of Indian Ophthalmic Practice. It deals with the grave injuries to the eyes inflicted by the use of primitive methods of treating conjunctivitis, trachoma, corneal opacities, and so on, and its debonair style is somewhat ill-suited to the recording of tragedies.—Captain J. A. Pringle reports a good case of multiple aneurysms of a retinal artery, associated with opaque nerve fibres. This paper is illustrated by an excellent coloured plate.—The report of a case of quinine amaurosis by Dr. Arthur J. Ballantyne is particularly noteworthy in that an early stage was observed in which the retinal arteries were not constricted, as is almost invariable in this form of poisoning. The case is very carefully discussed and good reason is shown for the view that the blindness is due to the direct toxic action of the drug upon the retinal elements, and not, as has been generally thought, to ischaemia.—There is a noteworthy sketch of the life of William Mackenzie (1791-1868), the great Glasgow ophthalmologist, by Dr. J. Freeland Fergus. The author writes his name "McKenzie," though he is generally known as Mackenzie, and this is the mode in which his name appears upon the title page of his own treatise on Diseases of the Eye. The facts of Mackenzie's life are well set forth, but the paper gives the impression of a somewhat grudging tribute to his genius. To state that he "has left practically nothing which will be permanently associated with his name" is an admission of the shortness of human memory and of the transitoriness of fame. To say that "he was not an investigator" is to detract from one of the greatest clinicians that ever lived. His original observations were far more numerous than Dr. Fergus gives him credit for, and they were so accurate that they are taught as the commonplace knowledge of to-day. Amongst the many abstracts of papers contained in these two numbers there is a valuable series on war injuries. The proprietors of the *British Journal of Ophthalmology* are to be congratulated on the success of their magazine in spite of the unusual difficulties produced by the war. That it is indispensable to ophthalmic surgeons and is not without its appeal to a wider circle are matters on which we congratulate the editor and his supporters.

**Endocrinology.** Vol. I., No. 1. January, 1917.—The first number of this new quarterly, published by the Association for the Study of Internal Secretions (secretary, Dr. Henry R. Harrower, Glendale, California; subscription \$5 a year in advance, single copies \$1 50 post paid), contains an introductory article by Lewellys F. Barker, of Baltimore, who believes that its appearance will be welcome to clinical and laboratory investigators, as well as to the "more alert general practitioners, for these men already realise the profound importance of an intimate knowledge of the ductless glands and their functions for everyday work in diagnosis and therapy." C. E. de M. Sajous, of Philadelphia, contributes an editorial article on the Future of the Internal Secretions, in which he describes organotherapy as opening up avenues of thought to a new conception of medicine which will satisfy the longing for logical reasoning and rationalism. He believes with Abderhalden that the tissue cell disposes of the same or similar ferments to those secreted by the digestive glands and that the leucocytes are the carriers of these ferments. Other brief editorial articles are written by Tom A. Williams, of Washington, and Henry R. Harrower, of Los Angeles. Three original articles follow: the first by Dr. Emile Sergeant, physician to the Charité, Paris, calling attention to the "ligne blanche surénale," which suggests to him the search for other signs of "hypo-adrenia." The rest of the volume is occupied by 60 pages containing nearly 200 brief abstracts and reviews of articles on internal secretions in the medical journals of the world.

## THE CONTROL OF VENEREAL DISEASES.

### Civilian Treatment Centres in France.

In his recent book on the problems of syphilis under French military régime ("La Syphilis et l'Armée." Paris : Masson et Cie. 1917. Price 4 fr.), Dr. G. Thibierge devotes a section to the creation of treatment centres for the civilian population. In Paris medicaments for the treatment of syphilis have long been distributed on a large scale at the special hospitals of St. Louis, Broca, and Cochin. From 1902, when mercurial injections became general, Dr. Thibierge and Dr. Brocq greatly extended the out-patient treatment of syphilitic women at the Hôpital Broca, other hospitals following suit with similar polyclinics. Sunday and evening consultations were arranged to suit all, and no pressure was placed on the patients to attend. Similar services were arranged in most large towns. In March, 1916, these services were still further extended on the advice of Inspector-General Vaillard and M. Brisac, director of assistance and public hygiene, and it was decided to institute dispensaries, called *services annexes des hôpitaux*, in every district where there was a call for them. gratuitous treatment to be provided under conditions of strict secrecy and with the help of military doctors if civilian practitioners were not available. In a circular dated May 31st, 1916, the Minister of the Interior instructed departmental prefects to bring pressure on local sanitary authorities to institute centres, and assured them of financial help from the State. Dr. Thibierge states that only in a few cases were the authorities recalcitrant, and that the number of patients attending the centres has increased with great rapidity. He mentions Dr. Pautrier, of Bourges, as an enthusiast whose example has set the tone of the work in general.

### Port of London.

The City Corporation is starting a treatment centre at the Royal Albert Docks at an estimated cost of £600.

### Publicity.

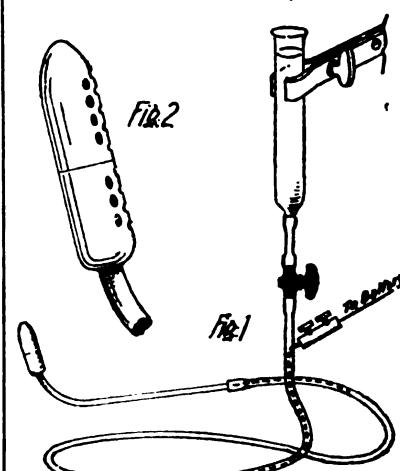

Dr. Harold Kerr, medical officer of health for Newcastle-on-Tyne, has issued a circular, published in full by the local press, calling attention to the facilities provided for treatment as well as to the need for such treatment. He asks all into whose hands the circular may come to use their "personal influence to promote the knowledge of good and evil that alone can save many from the consequences of ignorance," and to assist the sanitary authority by making the facilities provided widely known.—Following on an address given by Sir Francis Champneys at a public meeting in Glasgow on March 12th, a local branch was formed of the National Council for Combating Venereal Diseases. The

suggestion was made that further branches should be established at Edinburgh, Aberdeen, and Dundee.—Sir Malcolm Morris and Sir Thomas Barlow addressed a meeting of ministers of religion at the Small Queen's Hall on March 9th on the necessity for their co-operation in the campaign of publicity and enlightenment.

## New Inventions.

### AN ELECTRODE FOR THE IONIC TREATMENT OF PROSTATIC ENLARGEMENT.

I HAVE found that the enlarged prostate can be treated successfully by ionisation, and have designed an electrode for the purpose. The negative wire from the battery passes by a terminal right through the tube conveying the fluid down to the bulb of the instrument. The stem of it is insulated as far as the bulb, thus ensuring that no contact is made with the lower part of the rectum. The bulb is lubricated with glycerine and passed into the rectum well on to the prostate. The current I use is 20 millamps for half, increasing to one, hour on alternate days. As some irritation may be caused by the introduction of the bulb I have occasionally found it necessary to have the patient introduce a 4 gr. morphia suppository half an hour before coming to

me. Three to six months are required to effect the reduction, according to the age of the tumour. One case of ten years' standing took nearly twelve months. I was able to send away a man of 50 with a perfectly normal prostate and able to urinate freely, after only three months' attendance, but his condition was of only eighteen months' duration.

The instrument illustrated (Fig. 1) is designed to carry out the principle that there should be a constant supply of the fluid from which it is proposed to derive the ions at the seat of application. The face, which is perforated with a number of small holes (Fig. 2, shown on a larger scale) is pressed on to the prostate, and the hollow bulb (which unscrews in the centre) is packed lightly with cotton wool sufficient to ensure a steady trickle of fluid from the reservoir (the cylinder of a 2-ounce syringe inverted), on which a vulcanite tap regulates the outflow so that just sufficient runs down to last for the period of the sitting. Ten grains of potassium iodide dissolved in 2 ounces of sterilised water is the usual quantity.

Sydney, N.S.W. LEIGHTON KESTEVEN, M.R.O.S. Eng.

**BRISTOL HOSPITAL SUNDAY FUND.**—Up to the present £2252 have been received as a result of the Hospital Sunday collections in Bristol, and of this sum £2000 have been awarded to the local medical institutions.

**THE FOOD PROBLEM.**—Lecturing on the "Food Problem" at the Institute of Hygiene on March 15th Mr. J. Grant Ramsay, principal of the institute, said that both health and money would be saved by a better knowledge of food values, while, in addition, the public must be brought to realise that internal waste—i.e., food that could be done without—represented a squandering of health as well as of food. Mr. Ramsay detailed his proposal of a ration-book which had been submitted to the Ministry of Foods. This was to be a compulsory housekeeping book issued officially, in which all foods bought would be entered by the tradesman. The housekeeper would be saved from making the entries and the tradesman from drawing up any other account. Such a ration-book would provide an exact record of food bought, induce care and economy, and allow each individual to claim his fair share of rations.

# THE LANCET.

LONDON: SATURDAY, MARCH 24, 1917.

## "War Nephritis."

IN a recent discussion at the Royal Academy of Medicine in Ireland Dr. T. GILLMAN MOORHEAD and Dr. R. J. ROWLETTE took the view that the condition thus described is due to an infection, an impression which seems to be gaining ground among many observers. Dr. W. M. CROFTON related six cases in which he had administered a vaccine from organisms obtained from the urine with apparent benefit, but, as pointed out by other speakers, it is difficult to substantiate this claim in a disease which tends to spontaneous improvement. Some important observations have been made by TRÉMOLIÈRES and CAUSSADE on the renal functions in these cases.<sup>1</sup> They employed three tests for renal permeability—the effect of injections of indigo carmine, the elimination of chlorides, and the estimation of the urea in the blood. In this country the two methods have been employed in war nephritis by Mr. J. TREVAN at St. Bartholomew's Hospital, but as far as we know the indigo carmine method had not been previously tried. They injected subcutaneously 4 c.c. of a 4 per cent. solution in sterile distilled water. The excretion of the dye should normally begin in 20 minutes, reach its maximum in half to one hour, and be completed in 6 to 7 hours. In war nephritis it is possible for an exaggerated elimination of the dye to coexist with chloride retention. A drawback to its use is that it may provoke haematuria. They noted the same effect after the administration of 10 grammes of salt, but this never occurred in the 21 cases thus examined at St. Bartholomew's. With regard to the urea in the blood, they are of opinion that the usually accepted figure of 0'04 per cent. is too high; the average for soldiers without any renal lesion was 0'0265 per cent. They do not appear to have used the estimation of urinary diastase, which was found so useful by MACKENZIE WALLIS and subsequently by ADLER. From the results obtained by applying these three methods TRÉMOLIÈRES and CAUSSADE classified the cases of nephritis as follows:—

(a) Cases with insidious onset; these constitute one third of the total, and they respond normally to the tests for renal permeability. The albuminuria is the only renal symptom. They can be subdivided into two clinical types. In 10 per cent. of the total the albuminuria becomes intermittent and finally disappears, and recovery is apparently complete. In 24 per cent. there is residual albuminuria which is variable in amount, and not influenced by exertion. The physical value of such soldiers is diminished, but is sufficient. Some, however, have a persistent albuminuria, which is readily increased by fatigue and dietetic excess. Such cases may be on the way to chronic nephritis and the prognosis should be guarded. (b) Cases with acute onset. These again can be subdivided into two groups. 44 per cent. of the total show increased elimination of indigo carmine, with retention of chlorides, oedema, and haematuria. These may improve to the stage of simple albuminuria with normal renal permeability or may become chronic. 14 per cent. show more

extensive damage; the patients are usually above 30 years of age and complain of cramps and dead fingers. The elimination of indigo carmine is diminished, there is retention of chlorides, and the urea in the blood is increased, reaching 0'055 to 0'1 per cent. This excess of urea in the blood soon yields to a low nitrogen diet. Some of these may still be fit for military service; they have a normal heart without hypertrophy and the blood pressure is not more than 170-180 mm. They have not got chronic nephritis and their incapacity does not seem a definite bar to military service. (c) 7 per cent. quickly assume the features of chronic nephritis with cardiac hypertrophy, gallop rhythm, accentuation of the second sound at the aortic base and a rise of arterial tension. They are unfit for further military service. Death may occur from uræmic convulsions, pericarditis, or acute oedema of the lungs.

It will be noted that the French authorities recommend the retention of a far larger proportion of such patients for active service than is now the practice in the British Army. By a recent Army Order all cases of nephritis among our troops are kept in hospital for three months, and if then free from albumin are only to be employed for home service. Soldiers over 38 who have had nephritis and who show any cardiovascular change with persistent albuminuria are to be invalidated out of the service. Soldiers with persistent albuminuria, but without cardio-vascular change, are not to be retained in a higher category than C3. This more cautious policy is based on the liability to recurrence which has been observed, and seems to be the wisest course.

## The Moral Imbecile.

A WOMAN named ALMA COURTWRIGHT, 28 years of age, was recently convicted at the Old Bailey upon charges of robbing ladies who had engaged her as a servant, and after previous convictions for like offences had been proved against her was sentenced to penal servitude for five years. Before this was done the Court had been informed that the prisoner, after leaving prison in 1913, had been "certified as a moral imbecile," but that a Poor-law medical officer had declined to certify her as insane. The police view of the case was that she was one of the cleverest of her class, a plausible and dangerous criminal, and the judge is reported as having said, in passing sentence, that she "might be a moral imbecile," but that she was also an ingenious, clever thief. The observations quoted illustrate the attitude of the criminal law of the United Kingdom and the majority of those who administer it towards a fairly large class of prisoners, who, being without the same safeguards, are nevertheless treated by both judge and jury precisely as those prisoners are treated who show no signs of mental deficiency. That this is just cannot reasonably be asserted, but it is not a matter in which the general public is greatly interested. That it is undesirable is, however, realised by medical men more generally than by laymen. Members of the legal profession practising at the criminal bar, and judges, for the most part, display a scepticism which may be described as traditional when the irresponsibility of the committer of a criminal act is suggested, and very few lawyers not directly concerned with the administration of the criminal law are interested in questions connected with it.

<sup>1</sup> Annales de Médecine, vol. iv., No. 1, Jan.-Feb., 1917.

In the United States of America there is a greater tendency to investigate problems relating to crime, the power of individual States to initiate their own experimental reforms independently of their neighbours contributing to produce results which, even when not wholly successful, are instructive. The Municipal Court, Chicago, which tries criminal and civil cases, more or less comparable to those heard by our magistrates and county court judges, established during the year 1914 a psychopathic laboratory, to which notice has been given in these columns,<sup>1</sup> and not only defendants but sometimes witnesses suspected of mental defects are referred to it by the various branches of the Court. ALMA COURTWRIGHT would have obtained more satisfactory treatment, from the medical point of view, in Chicago, for as a chronic offender she would have certainly come in for investigation at the laboratory. The difficulty of dealing with chronic offenders prompted the foundation of the institution, which has followed upon the establishment in the United States of America of various types of prisons and reformatories where industrial education is given, and of systems of releasing prisoners on probation or parole. These innovations have introduced a wide range of possible sentences for a judge to choose from, and have rendered desirable full information on his part if he is to choose rightly. Those who have instituted the laboratory have recognised this fact, and also that there exists a close connexion between mental and physical defectiveness and criminal conduct. The report of the Municipal Court of Chicago recently issued points out clearly that it is the defective born in surroundings of poverty and moral danger who become criminals. Better circumstances safeguard the defective from crime. The child of poor parents who acquires the reputation of being lazy, perverse, or stupid at school is removed thence at the earliest opportunity because he makes no progress, and is sent out to work for his living, only to find the discipline of employment even less helpful than that of school, and his deficiency still a bar to his success. He becomes used to failure, so that he expects it, as others do for him. His appetites and desires are not less than those of his normal colleagues, but he has not their capacity for inhibition and for realising the wrongness or the consequences of evil-doing, and so his downfall becomes natural and easy. But it was his poverty that largely contributed to his total failure; with money he could have been sheltered and, possibly, much improved.

The report goes on to discuss what should be done with the criminal who is found to be feeble-minded, or whose case is complicated by the diagnosis of dementia praecox, and recommends confinement for the latter class in farm-colonies under proper supervision. The question of procedure in diagnosing and eliminating the feeble-minded from the ranks of the ordinary criminal must, however, be decided before their disposal can be usefully discussed, and perhaps in some future year the example of Chicago may be found valuable as a guide. In this country we have recently passed

an Act of Parliament dealing with mental deficiency in a comprehensive manner, and in more settled times the experience gained in its administration may produce good results. The case we have cited shows, however, that at present we do not deal satisfactorily with those who, though not in a condition to be confined as lunatics, nevertheless are a danger to the community owing to mental defects. Young persons who are in process of becoming thus dangerous should be our prompt care, recognising the importance of early treatment as a preventive measure. In this connexion attention may be called to the general complaints now being made of juvenile crime and depravity. It may be assumed reasonably that of the young persons of both sexes who are to-day giving trouble on an unprecedented scale, and who are stated to be unruly in the absence of their parents, or to be the victims of the sinister influences of picture palaces, or to be unable to withstand the temptations of darkened streets, some are those whose mental equipment is a little less than normal. Possibly their parents have bequeathed to them an undesirable inheritance, and, being defective themselves, have been bad educators of their offspring; at all events many of these juvenile delinquents cannot fairly be judged by normal standards.

### Arsenic in Food Preparations.

A NOTE issued in October last year by the Chief Inspector of Foods pointing out to public analysts the desirability of examining baking powders, egg-powders, self-raising flours, and so forth, for arsenic, has been justified by subsequent events. At Maidstone, for example, the county analyst, Mr. F. W. F. ARNAUD, has reported several instances of arsenical contamination of these food preparations arising out of their containing impure acid phosphate. In two instances an excessive amount of arsenic was detected in egg-powder: it contained, in fact, 10 parts of arsenic per million, while a baking powder contained 6·6 parts per million. Two samples of egg-powder received from the local sanitary authorities were also found to contain excessive amounts of arsenic. In 26 samples of egg-powder and baking powder no arsenic was detected, but in the remainder of the samples arsenic varied in amounts from 0·1 to 3·0 parts per million. Arsenic was absent in four of the self-raising flours, but 19 samples contained it in quantities varying from 0·2 to 2·0 parts, the average amount found in these samples being rather more than 1 part of arsenic per million. The Royal Commission on Arsenical Poisoning recommended that action should be taken under the Sale of Food and Drugs Acts when any liquid is found to contain 1/100th of a grain or more of arsenic in the gallon, or when any solid contains 1/100th grain of arsenic or more in the pound. This amounts to 1·43 parts per million, a limit which will be seen is largely exceeded in some of Mr. ARNAUD's cases. Again, at Stratford police court last week a grocer was convicted of selling baking powder which was contaminated with 1/18 grain of arsenic per pound. Our public health authorities will need to exercise increased vigilance over the food-supplies just now, for much departure from pre-war standards is allowed, and this increases the temptation to use inferior and possibly contaminated materials.<sup>2</sup>

## Annotations.

"*Ne quid nimis.*"

### THE EFFECT OF THE WAR ON THE SUPPLY OF DRUGS.

A VERY interesting and instructive review of the position of the supply of drugs in war time was given in a paper read before a recent meeting of the Royal Society of Arts by Mr. F. A. Hocking, B.Sc., pharmacist to the London Hospital. At the outset it is good to learn from one who knows that while much has been written and said concerning our real or supposed dependence on Germany for medicinal chemicals, the situation here has for the most part been described with some exaggeration. While not underrating the position of the enemy in this matter Mr. Hocking rightly says that it is not necessary to fall into the opposite error of unduly depreciating the abilities and resources of our own country. It is not true to say that Germany was the source of all drugs of any importance, and that with the outbreak of war supplies ceased. As examples opposed to this extreme view are quoted the alkaloids, the number of which, or their salts, used in the London Hospital in the year 1914 was about 15. Of these, seven—namely, apomorphine, acetomorphine, morphine, codeine, caffeine, strychnine, and emetine—were, and are, manufactured in England on a large scale, not merely for home consumption but also for export to all parts of the world, and both for quality and quantity these English products, Mr. Hocking says, rank easily first. Coming to anaesthetics and antiseptics, ether, chloroform, ethyl chloride, carbolic acid, creosote, and iodoform are produced in this country in large quantities. The same is true of alcohol and glycerine, now so urgent, however, in the production of munitions. Germany held the field chiefly in the matter of synthetic drugs; but synthetic drugs do not constitute the whole *materia medica*, and the more important of them—e.g., acetosalicylic acid, novocain, veronal—are now being made in England. It is further interesting to learn that the production of iodine from Chili saltpetre is largely controlled by Great Britain, and while the price of potassium iodide rose a few shillings per pound in December, it has since fallen to practically the pre-war figure. Potassium bromide is perhaps the best example of a big rise in price owing to the monopoly left in the hands of American dealers by the shutting off of German supplies. In July, 1914, the price of bromide of potassium was 1s. 6*d.* per pound; at one time it reached the figure of 25s. per pound, and is now quoted at about 7s. 6*d.* per pound. France is competing with the American product by manufacturing bromine from sea water in substantial quantities. It is hoped to revive the kelp industries in Scotland and Ireland in which potash from sea-weed ash is recovered. Potash minerals have been discovered in important quantities in Spain, which later may prove to be a source of serious competition to the German industry at Stassfurt. Altogether it seems that the pharmaceutical world can get on quite comfortably without German intervention, if proper care is taken in the future to organise the drug and allied industries with the view of securing them permanent prosperity. Such a consummation would be clearly prejudiced if the following incident, quoted

in the paper, be allowed to be repeated. It appears that when acetomorphine was first made and introduced in England by a Scotch firm, but little interest was manifested in it by the medical profession, whereas the same drug put on the market by the Germans under the name of "heroin" was taken up with alacrity.

### REPORT FOR 1915 OF THE REGISTRAR-GENERAL FOR IRELAND.

Sir William Thompson's report on Irish Vital Statistics which has just been published contains several features of public health interest that invite special attention in time of war. In the absence of his former medical colleague the Registrar-General appears to have been solely responsible for the preparation of all reports issued since the outbreak of hostilities; nevertheless, the present volume fully sustains the high character of its predecessors. Prominent among statistical matters, it is noteworthy that the loss of population by emigration from Ireland in 1915 was proportionally the lowest on record, being only 2·5 per 1000 living at all ages, or less than half the ratio in the preceding year. The marriage-rate was the highest hitherto attained, but the birth-rate still continues to fall, being equal to 22·0 only per 1000 of the population. The death-rate at all ages, as well as among infants in their first year, was somewhat higher than in the previous year. It is satisfactory to observe in the present report a considerable amplification of the statistics of mortality in the earlier years of childhood. Great disparity is shown in the loss of infant life in the urban as compared with the rural districts of Ireland, the rate of infant mortality in the 27 principal towns averaging 134 per 1000, or no less than 92 per cent. in excess of that in the remainder of the country. If the rate of mortality in the town districts had been the same as in the rest of Ireland there would have been in 1915 a saving of 2072 infant lives. Compared with the preceding year there was an increase in the mortality from bronchitis of 1·84 per 1000 births and of 1·34 per 1000 from wasting diseases, whilst there was a decrease of 1·94 per 1000 in the mortality from diarrhoeal diseases and a decrease of 0·57 per 1000 in the mortality from measles. Locally the incidence of infant mortality varied enormously. Corrected for births and deaths in institutions the rate was highest, 163 per 1000, in Dublin, 158 in Queenstown, 155 in Newtowndale, and 143 in Londonderry. It was lowest, 44 per 1000, in Bray and next lowest, 64 per 1000, in Tralee. In the year under review there was, as compared with the decennial average, a fall in the aggregate mortality from common epidemic diseases except scarlet fever and influenza. The deaths from tuberculous disease numbered 9525 and were equal to 12·5 per cent. of the deaths from all causes. In the year 1910 the deaths thus returned had amounted to 10,016, but from that date onwards the number fell annually, until in 1914 they reached 9089, when they were the fewest on record. Stated in terms of population, tuberculous mortality in 1915 corresponded to a rate of 2·20 per 1000 living of both sexes, which was 0·13 above the rate of the preceding year, but still below the average rate in the preceding decennium by 0·19 per 1000. The rate was 1·5 per 1000 in England and Wales and 1·6 per 1000 in Scotland. In Ireland the male population suffered from fatal tuberculosis at the rate of 2·28 per 1000,

or 0'17 in excess of the rate in the previous year, whilst the female population suffered at the rate of 2'11 per 1000, or 0'07 above the rate for that year. It appears that the decrease in tuberculous mortality is progressing more rapidly among females than among males. About four-fifths of the deaths from tuberculous disease were ascribed to the pulmonary form of the affection, the deaths from which in 1915 were equal to 1'81 per 1000 among males and to 1'67 per 1000 among females. As in England, this disease is especially destructive to young adults of both sexes, 73 per cent. of the total deaths being those of persons between the ages of 15 and 45 years. No diminution is recorded in the mortality from malignant disease, the deaths in the year under review being equal to 88'2 per 100,000 of the population, as compared with 81'2, the average rate in the ten years 1905-1914.

#### THERAPEUTIC VALUE OF DIRECT SUNLIGHT ON SCURVY.

⑧ Naval Staff Surgeon Dr. Asbeck was detailed in May, 1915, to tend the Turkish wounded in the Reserve Hospital Harbié at Constantinople, and he relates, in the War Supplement of the *Münch. med. Wochenschr.* of Jan. 9th, how in the following autumn and winter scurvy was one of the worst enemies he had to deal with. The number of wounded men was, he says, at that time so great that it was impossible to supply them all with tinned vegetables, and all grades of scurvy were in evidence, from grouped cutaneous petechiae, favouring the thighs, to large haemorrhages into the subcutaneous tissue, joints, and serous cavities. Wounds were brownish-black in colour with glazed surface, bled freely at each dressing, and showed no tendency to skin over. Insolation effected immediate improvement in all this and as the direct sunlight increased in intensity with the season, both wounds and scorbutic ulcers rapidly healed under the treatment, the diet remaining meanwhile unchanged. By June no case of scorbutic ulcer remained in the hospital. Alike with the local improvement the general condition mended, the patients who had all been heavy and depressed becoming gay and light-hearted after their sun-baths.

#### DIETARY ALLOWANCES.

THE Local Government Board has issued a schedule to the boards of guardians to help them in framing their dietaries so as to bring the consumption of flour, meat, and sugar within the scale specified by the Food Controller. No dietary tables which admit of an average consumption of those foods in excess of the scale will remain in force after March 31st next. The schedule permits three-fourths of the bread allowance to be replaced by other foods, and for this purpose the following are deemed equivalent to 1 lb. of bread or  $\frac{4}{5}$  lb. of flour—namely,  $\frac{4}{5}$  lb. of barley, oatmeal, rice, sago, tapioca, or maize meal; or 5 oz. of butter, margarine, or fat. The caloric value of the pound of bread is exceeded by the oatmeal allowed, and is equalled, or nearly so, by the other foods. If sago, tapioca, or the fats are used, the quantity of protein furnished is reduced, but as the dietary contains other protein-rich foods, no harm is likely to arise on this account. Any wilful waste of bread is to be treated as a breach of discipline. A pound of meat, without bone, may be replaced by 5 oz. of cheese or by 8 oz. of beans, lentils, or peas. There is less food value and protein in these than in

the meat, but the liberal standards of times of peace and plenty cannot be defended at present. Some saving of sugar is also recommended by the substitution of syrup, treacle, honey, saxon, or saccharine. On the whole, when the need for stern economy is considered, the recommendations are on a liberal scale. The schedule recognises the need of elasticity in feeding children, and calls upon the medical officer to advise in the substitution of foods according to individual requirements, so as to secure that each child shall be adequately fed without waste. He is, of course, solely responsible for the food of the sick and of infants, but his attention is called to the desirability of effecting any economies compatible with their needs.

#### HORSE-SICKNESS OF RHODESIA.

In the *Rhodesia Agricultural Journal* Mr. L. E. W. Bevan, M.R.C.V.S., Government veterinary bacteriologist, refers to this disease which affects horses and mules, and caused a loss of £30,000 to the colony in the year 1911. It is due to an ultra-visible virus contained in the blood, exudates, and bronchial secretions of animals affected. It is communicable to dogs by inoculation and by feeding upon infected meat. Animals that recover from the disease acquire a certain degree of immunity, but this is not complete against reinfection. Theiler found that "the serum of an immune animal which has periodically been immunised acquires immunising properties." The immunising of mules against horse-sickness has been practised in the colony since 1895. This is done by a simultaneous injection of serum and virus, and Southern Rhodesia has derived enormous advantage from it.

#### MEDICAL SIMILES IN LITERATURE.

ONE of the great differences presented between the general literature of the masters of the nineteenth and twentieth centuries and the works of their predecessors, both immediate and remote, is the disappearance of the medical simile. The reasons for this are well summed up in an attractive paper by Dr. W. R. Jordan in the January issue of the *Midland Medical Journal*. Dr. Jordan points out that the scholar of the Renaissance took all learning as his province, anatomy, physiology, and psychology with the rest, and used that learning to illustrate his points and exemplify the types of his creation. The medical learning of such a scholar was necessarily derived largely from the treatises of Galen and his great forerunner Hippocrates. Hence the medicine of imaginative writers from Rabelais and Shakespeare at one end to the age of Anne at the other is derived from Hippocrates; for it was at least 50 years after Harvey's great discovery before its meaning was obvious to readers as well as writers to an extent that would make the introduction of similes drawn from Hippocratic medicine appear ridiculous. Rabelais, physician as well as priest, lectured upon the works of Hippocrates and Galen, and it is natural that his immortal medley should be full of allusions to their science. The so-called First Book of Rabelais, or chronicle of Gargantua, contains elaborate anatomical remarks on page after page, and throughout all the Books a knowledge is shown by the writer, and assumed by him for the reader, of the physiology of the day. Next to Rabelais comes Shakespeare in his love of the medical simile, founded on the physiology and pathology which were universally

accepted before the publication of Harvey's discovery. Such physiology and pathology lent themselves extraordinarily well to literary similes, the reason for this being that they resolved themselves into general doctrines, supported by authority, and uncomplicated by opposing theories. Matter was composed of four or five elements having certain elementary and opposing qualities. The human body was a mixture in average proportions of these things, variations in those proportions giving rise to the different temperaments. "From the doctrine of the four elements to that of the humours is an easy translation," says Dr. Jordan, "for there was a close relation between the two; indeed, the term elements is occasionally somewhat loosely applied to the humours and also to the elementary contraries." Galen set forth the relations between the humours, the elements, and their qualities, and complicated the story by introducing the season of the year as a factor in pathology. Upon physiology and pathology of this kind Chaucer, Bacon, Ben Jonson, and especially Shakespeare, perpetually drew, while Dr. Jordan's quotations from many authors prove that numerous passages, which are quite well known, and some which are frequently quoted, lose their exact application for readers who cannot appreciate the origin of the metaphors employed or the reasons for the phraseology.

#### THE PROGRESS OF THE ROYAL MEDICAL BENEVOLENT FUND.

WE publish in another column a short account of the annual general meeting of the Royal Medical Benevolent Fund, which was held last week. We have regularly noted the activities of the Fund from month to month, and can assume that our readers are familiar with them; but the report, which was laid before the supporters of the Fund, presented features to which particular attention may well be drawn. The retirement of Sir John Tweedy from the Presidency was announced at the meeting, and brought into prominence the facts that during his decade of office the Fund had obtained a Charter of Incorporation and the Guild, or Ladies' Branch in connexion with the Fund, had been started. The Guild has done, and is doing, a work of steady and unobtrusive charity. The election of the honorary treasurer, Dr. Samuel West, to succeed Sir John Tweedy as President afforded an opportunity for calling attention to the organisation of the finances of the Fund, which had taken place during the 22 years of Dr. West's treasurership. Within that period the output of the Fund in charity has doubled, the invested property has risen, in rough figures, from £50,000 to £100,000, and the number of annuities granted has increased by more than 50 per cent. This is a great record of administrative work, and would by itself commend the Fund to wide support, but at this juncture a further claim is made by it upon the attention of all members of the medical profession, in order that they may use their influence among their patients. The Fund has made a War Emergency Appeal with special reference to the claim which the medical profession has on the public. Many doctors, owing to their sudden call to naval and military duty, have had to leave their practices inadequately provided for, and on their return will no doubt find them impaired by their absence despite anything which the Central Medical War Committee may desire or propose to the contrary. To

meet the difficulties the War Emergency Appeal has been started, and substantial sums may have to be granted, but the amount at present available is quite insufficient. The Fund will no doubt have heavy demands made on it. The public realises the splendid services rendered by the medical profession in the war, and it is hoped that they will give the Emergency Appeal liberal support. The most effectual way in which this can be done is by medical men bringing the movement and its needs to the notice of their well-to-do patients.

#### THE METROPOLITAN WATER-SUPPLY.

THE issue this week of the report on the condition of the metropolitan water-supply during the month of December, 1916, concludes the monthly returns for that year. The last reports we dealt with referred to the condition of the supply during the months of August, September, and October. November was a comparatively wet month, the mean rainfall in the Thames basin being 4·28 inches, which is 1·58 of an inch above the mean rainfall for that month during the previous 33 years. The effect on all the three raw waters (Lee, Thames, and New River) was a deterioration in quality, as judged by the albuminoid nitrogen, permanganate, turbidity, and colour tests. The filtered waters likewise deteriorated in quality, according to these tests, except that the filtered water of the Lee river showed no change as regards colour. Compared with the 1915 averages all three raw waters yielded results worse than their respective averages. The filtered waters also yielded, generally speaking, results worse than their respective averages. In regard to bacteriological results all three waters contained more bacteria than their respective averages for the year 1915, but the filtered waters yielded not unsatisfactory results, 93·1, 90·9, and 56·4 per cent. of the filtered waters derived from the three river sources containing no typical coli even when 100 cubic centimetres of the water were examined. In December the mean rainfall was 3·41 inches, or 0·39 of an inch above the average for this month during the previous 33 years. Some improvement in the chemical quality of the raw waters was shown on the previous month, and compared with the 1915 averages there was improvement in the raw Thames water, but some deterioration in the Lee and New River waters. The filtered waters also showed some deterioration in quality and contained more bacteria than their respective averages for the year 1915, the results showing that 67·4, 50·0, and 41·1 per cent. of the filtered waters respectively contained no typical *B. coli* in 100 cubic centimetres.

THE house of the Royal Society of Medicine will be closed from Thursday to Tuesday, April 5th to 10th, both inclusive.

IN the Education Estimates issued on Monday last a grant of £1,000,000 is announced for the encouragement of scientific and industrial research. The dispensation of the money is vested in the hands of a committee of the Privy Council.

A PAPER by Surgeon-General Sir C. Pardey Lukis, K.C.S.I., K.H.S., M.D., F.R.C.S., on "Opportunities for Original Research in Medicine in India," will be read at a meeting of the Indian Section of the Royal Society of Arts, on Tuesday, 27th inst., at 4.30 P.M. The paper will be followed by a discussion.

**REGISTRAR-GENERAL'S ANNUAL SUMMARY  
FOR 1916,  
AND RETURN FOR THE FOURTH QUARTER.**

To Sir Bernard Mallet's return for the fourth quarter of last year a considerably abridged summary is appended, giving the principal information respecting births, marriages, and deaths contributed by the local registrars in the complete year 1916. In commenting on the last quarterly return in THE LANCET of Dec. 16th, 1916 (p. 1024), we referred to the discontinuance, as a separate publication, of the familiar "Annual Summary" which had been issued from the Central Office for a large number of years. This publication has always been highly appreciated by local medical officers of health, who are thus supplied with valuable matter not otherwise available for the compilation of their annual reports. A brief analysis of the mortality tables of 1916 appeared in our issue of Jan. 27th, 1917 (p. 162). Of the total deaths 45·6 per cent. took place in public institutions in London, 29·6 per cent. in the great English towns, and 16·4 per cent. in the smaller towns. In the fourth quarter of 1916 the birth-rate of England and Wales was 20·1 per 1000 living, or 0·6 more than in the corresponding quarter of last year. The natural increase of population, by excess of births over deaths, was 46,961, an enormous drop from the figure for the year before the war, when it was 89,045. The deaths registered during the quarter were equal to 14·9 per 1000 of the assumed population. Infant mortality was equal to 99 per 1000 births, being 19 per 1000 below the average for the quarter, and, with one exception, the lowest on record for the fourth quarter of the year. In the usual table the death-rate from the several causes are given for the several towns, the figures relating to the civil populations only. Among the great towns the highest death-rates per 1000 from epidemic diseases were as follows: From enteric fever 0·31 in Burnley and 0·34 in Tynemouth; from measles 1·18 in Edmonton and 1·26 in Coventry; from scarlet fever 0·13 in Gateshead and 0·22 in Walsall; from whooping cough 0·43 in Exeter and 0·95 in Great Yarmouth; and from diphtheria 0·88 in Carlisle and 1·00 in St. Helens. The returns of notifiable diseases show the following rates of sickness per 1000 living in London and the average rates in groups of provincial towns. The annual rate from enteric fever was 0·11 per 1000 in London, in 243 provincial towns it was 0·16, in 95 great towns 0·14, and in 148 smaller towns 0·22. From scarlet fever it was 1·61 in London, 1·99 in 243 provincial towns, 1·92 in the

great towns, and 2·18 in the smaller towns; and from diphtheria 2·18 in London and 1·39 in each of the other areas.

**URBAN VITAL STATISTICS.**

**VITAL STATISTICS OF LONDON DURING THE YEAR 1916.**

In the accompanying table statistics of sickness and mortality in the City of London and in each of the metropolitan boroughs are summarized for the year 1916. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the 10 diseases specified in the table was equal to a rate of 5·1 per 1000 of the population, estimated at 4,310,030 persons; in the three preceding years, the rates were 6·7, 9·0, and 7·1 per 1000 respectively. Among the various boroughs the rates last year ranged from 3·2 in Kensington and in the City of Westminster, 3·5 in St. Marylebone and in Hampstead, and 3·7 in the City of London, to 5·2 in Finsbury and in Deptford, 6·8 in Greenwich, 7·5 in Stepney, 7·8 in Shoreditch, and 8·4 in Bethnal Green. Only one case of small-pox was notified last year, against 11 in the preceding year. The prevalence of scarlet fever showed a great decline last year; 8766 cases were notified, against 25,015 and 17,104 in the two preceding years. Among the metropolitan boroughs the greatest proportional prevalence of this disease was recorded in Finsbury, Shoreditch, Bethnal Green, Stepney, and Deptford. The Metropolitan Asylums Hospitals contained 913 scarlet fever patients at the end of last year, against 4431 and 2431 at the end of the two preceding years; 8542 new cases were admitted during the year, against 23,154 and 16,327 in the two preceding years. Diphtheria was rather less prevalent than it had been in the preceding year; 8754 cases were notified, as compared with 9166 in 1915. This disease was proportionally most prevalent in Shoreditch, Bethnal Green, Stepney, Southwark, and Greenwich. The number of diphtheria patients remaining under treatment at the end of last year in the Metropolitan Asylums Hospitals was 1479, against 1663 and 1476 at the end of the two preceding years; the number of cases admitted during the year was 8883, against 8444 and 868 in the two preceding years. Enteric fever was considerably less prevalent than it had been in other recent years, only 463 cases being notified, against 758, 779, and 647 in the three preceding years. The greatest proportional prevalence of this disease was recorded in Paddington, the City of Westminster, St. Pancras, Holborn, Bethnal Green, Wandsworth, and Greenwich. The number of enteric fever patients admitted into the Metropolitan Asylums Hospitals during the year was 324, against 415, 470, and 446 in the three preceding years; 37 cases remained under treatment at the end of the year, against 51, 68, and 50 at the end of the three preceding years. The greatest proportional prevalence of erysipelas occurred in Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Deptford. The 277 cases of puerperal fever notified during the year included 22 in Fulham, 21 in Islington, 21 in Lambeth, 20 in Wandsworth, 18 in St. Pancras, 17 in Poplar, 16 in Bethnal Green and in Southwark, and 15 in Woolwich. The 427 cases of cerebro-spinal meningitis included 39 in Islington, 33 in Lambeth, 31 in Stepney, 27 in Wandsworth, 24 in

\* Including membranous croup.

Hackney, and 24 in Southwark. The 192 cases of poliomyelitis included 21 in Hackney, 20 in Poplar, 17 in Camberwell, 14 in Bermondsey, 13 in Islington, 13 in Southwark, 12 in Stepney, and 12 in Lambeth.

The mortality figures in the table relate to deaths of persons actually belonging to the various metropolitan boroughs, and are obtained by distributing the deaths in institutions among the boroughs in which the deceased persons had previously resided. During last year the deaths of 61,373 London residents were registered, equal to a death-rate of 14·3 per 1000; in the three preceding years the rates had been 14·2, 14·4, and 16·1 per 1000. The lowest death-rates last year were 10·3 in Hammersmith, 11·6 in Lewisham, 11·7 in the City of London and in Wandsworth, and 12·6 in Stoke Newington; the highest rates were 16·3 in Chelsea and in Holborn, 16·8 in Bermondsey, 17·0 in Southwark, 17·6 in Shoreditch, and 18·6 in Finsbury. The deaths from all causes included 4031 which were referred to the principal infectious diseases; of these, 815 resulted from measles, 146 from scarlet fever, 604 from diphtheria, 793 from whooping-cough, 75 from enteric fever, and 1568 from diarrhoea and enteritis among children under 2 years of age. The death rate from these diseases in the aggregate ranged from 0·1 in the City of London, 0·2 in Hammersmith, 0·4 in Kennington and in Stoke Newington, and 0·5 in the City of Westminster, to 1·4 in Bethnal Green, 1·5 in Poplar, in Southwark, and in Greenwich, and 2·0 in Shoreditch. The 815 fatal cases of measles were 1111 fewer than the corrected average number in the five preceding years; this disease was proportionally most fatal last year in Finsbury, Shoreditch, Poplar, Southwark, Bermondsey, and Greenwich. The 146 deaths from scarlet fever were 87 below the corrected average number; the greatest proportional mortality from this disease was recorded in Islington, Stoke Newington, Shoreditch, Stepney, and Poplar. The 604 fatal cases of diphtheria were 24 in excess of the corrected average number; this disease shows the greatest proportional mortality in Chelsea, Holborn, Shoreditch, Southwark, Bermondsey, and Greenwich. The 793 fatal cases of whooping-cough were 181 below the corrected average number; the highest death-rates from this disease were recorded in Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, Greenwich, and Woolwich. The 75 deaths from enteric fever were 56 fewer than the average, and included 10 in Islington, 7 in Stepney, 6 in Greenwich, and 5 each in the City of Westminster, St. Pancras, Shoreditch, Poplar, and Wandsworth. The mortality from diarrhoea and enteritis among children under 2 years of age was greatest in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, and Deptford. In conclusion it may be stated that the aggregate mortality in London last year from these principal infectious diseases was 42·7 per cent. below the average.

(Week ended March 17th, 1917.)

**English and Welsh Towns.**—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18,000,000 persons, the annual rate of mortality was equal to 18·5, against rates declining from 22·5 to 17·1 per 1000 in the four preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 19·3, or 0·8 per 1000 above that recorded in the previous week; among the remaining towns the rates ranged from 9·2 in Wimbledon, 11·3 in Rotherham, and 11·7 in Dewsbury, to 25·5 in West Hartlepool, 27·9 in Stockton-on-Tees, and 28·5 in Middlesbrough. The principal epidemic diseases caused 357 deaths, which corresponded to an annual rate of 1·1 per 1000, and included 194 from measles, 61 from infantile diarrhoea, 51 from whooping-cough, 42 from diphtheria, 6 from scarlet fever, and 3 from enteric fever. The deaths from measles showed a further increase on the numbers in the seven preceding weeks, and caused the highest annual death-rates of 2·2 in East Ham, 2·9 in Oldham, 3·4 in Walsall, and 6·5 in Warrington. The 805 cases of scarlet fever and the 1476 cases of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 6 below and 4 above the numbers at the end of the previous week. Of the 6140 deaths from all causes in the 96 towns, 196 resulted from violence. The causes of 59 of the total deaths were unascertained, of which 13 were registered in Birmingham, 9 in Liverpool, and 5 in Manchester, but only 1 in London.

**Scotch Towns.**—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death rate was equal to 18·3, against rates declining from 20·1 to 16·7 per 1000 in the four preceding weeks. The 382 deaths in Glasgow corresponded to an annual rate of 17·9, against 19·3 per 1000 in London, and included 24 from whooping-cough, 10 from measles, 6 each from diphtheria and infantile diarrhoea, and 1 from scarlet fever. The 135 deaths in Edinburgh were equal to a rate of 21·2 per 1000, and included 7 from whooping-cough, 4 from measles, and 1 each from diphtheria and infantile diarrhoea.

**Irish Towns.**—The 184 deaths registered in Dublin were equal to an annual rate of 24·0, or 0·3 per 1000 below that recorded in the previous week, and included 8 from measles, 3 from infantile diarrhoea, and 1 from whooping-cough. The 163 deaths in Belfast corresponded to an annual rate of 21·6 per 1000, and included 4 from measles, 2 from infantile diarrhoea, and 1 from diphtheria.

**ABERDEEN DISPENSARY: ANNUAL REPORT.**—The annual report of the Aberdeen Dispensary and Vaccine Institution states that during 1916 4749 cases were dealt with. In the ear, nose, and throat department 54 cases of syphilis, 42 being acquired and 12 congenital, came under observation. There was a deficit financially for the year of 6 guineas.

**THE BELFAST MATERNITY HOSPITAL.**—At the recent annual meeting of this old-established Belfast charity it was reported that 456 intern and 434 extern patients had been treated during the year 1916, with nine maternal deaths. The subscriptions had slightly increased. By raising a special sum of £500 the committee obtained a legacy of £500 left on these conditions. The Rev. Canon Carmody, one of the speakers, referred especially to the delay of the Belfast City Council in adopting a maternal and child-welfare scheme, as had been done by Dublin, Lurgan, Portadown, and Bangor.

## THE SERVICES.

### ROYAL NAVAL MEDICAL SERVICE.

Fleet-Surg. H. B. Beatty has been placed on the Retired List with the rank of Deputy Surgeon-General.  
J. C. McClelland to be Temporary Surgeon.

### ARMY MEDICAL SERVICE.

Lieut.-Col. G. B. Stanstreet, C.M.G., to be an Assistant Director-General (temporary).  
Col. A. P. Blenkinsop, C.B., to be temporary Surgeon-General whilst employed as Director of Medical Services of an Expeditionary Force.

### ROYAL ARMY MEDICAL CORPS.

Temp. Capt. C. B. Dobell to be temporary Major.  
Temporary Lieutenants to be temporary Captains: T. McC. Sellar, E. Ashby, C. H. L. Nixon.

A. G. Sher to be temporary Honorary Captain whilst employed with the British Red Cross Hospital, Netley.

To be temporary Lieutenants: G. Taylor, F. G. M. Simpson, W. G. McConnell, E. G. Bark, A. W. C. Bennett, B. C. Burnett, G. B. Bartlett, A. H. Mandell, A. W. Hall, O. H. Bullock, C. H. Medlock, H. O'Neill, O. F. D. Athrith, I. R. R. Brington, F. G. Chandler, W. J. Purdy, J. E. Foreman, R. M. Danks, J. Rae, S. M. Wilcox, M. W. Danzig, F. Cheal, W. Lumaden, H. D. McCall, M. A. Teale, A. Bevan, A. W. G. Clark, W. Templeton, J. Marshall, C. C. Kennedy, J. M. H. Caldwell.

Officers relinquishing their commissions: Temp. Hon. Major H. L. Tidy, having resigned his appointment at the British Red Cross Hospital, Netley; Temp. Hon. Major C. H. Milburn, having ceased to be employed with No. 2 British Red Cross Hospital; Temp. Capt. M. Litchfield and W. F. L. Day (on account of ill-health), and M. A. Farr; Temp. Lieuts. J. F. Young, J. B. Brown, R. C. Robinson, J. P. Ziervogel.

### SPECIAL RESERVE OF OFFICERS.

Lieutenants to be Captains: J. D. Dyson, H. M. Alexander, C. A. W. Ramsay, F. B. Macaskie, F. Gamm, J. A. Murray, B. Kean, R. Chevassut, J. H. Atkinson, R. Colley, A. K. Robb, J. J. Landers, J. E. Kitchen, E. Lipman, J. C. Attridge.

To be Lieutenants: G. V. Davis (from University of London Contingent, O.T.C.), H. A. G. Dykes, J. B. Mudge.

### TERRITORIAL FORCE.

Major (acting Lieut.-Col.) G. W. Miller relinquishes his acting rank on ceasing to command a Field Ambulance.

Capt. (temp. Major) R. Waterhouse to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. (temp. Major) F. Ward relinquishes his temporary rank on alteration in posting.

Capt. (temp. Maj'r) T. H. Chittenden to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. R. C. S. Smith, from East Anglian Casualty Clearing Station, to be Captain.

Lieuts. A. E. Crabbe and J. R. Mitchell to be Captains.

R. K. Ellison to be Lieutenant.

Major O. E. Bean relinquishes his commission on account of ill-health.

**Attached to Units other than Medical Units.**—Major W. B. Mackay, C.M.G., from T.F. Res., to be Major. Capt. H. W. Lawing to be Major. Capt. J. A. Simpson relinquishes his commission on account of ill-health. Lieut. J. W. Anderson to be Captain. Capt. A. C. Farquharson to be Major.

### VOLUNTEER FORCE.

J. O. Sankey (late Surgeon-Major, 1/4th Oxford and Bucks Light Infantry) to be temporary Captain and Medical Officer, Oxfordshire Volunteer Regiment, 1st Battalion.

### INDIAN MEDICAL SERVICE.

The King has approved the promotion of the following officers:—Majors to be Lieutenant-Captains: H. S. Peck, T. A. O. Langston. Major to be temporary Lieutenant-Colonel: G. McPherson. Temporary Lieutenants to be temporary Captains: R. C. P. Berryman, A. Williams.

The King has approved the retirement of Major G. King.

We regret an inaccuracy in our Annus Medicus for 1916 (*THE LANCET*, Dec. 30th, 1916, p. 1116, col. 2). It was there stated that Sir C. P. Lukis, D.G., I.M.S., was appointed to act as Director of Medical Services in India, and that the control of the whole medical service, civil and military, was vested in one officer, presumably for the duration of the war. Sir Charles Lukis's tenure of the appointment of Director of Medical Services lasted only until the arrival in India of the present Director of Medical Services, Surgeon General T. J. O'Donnell, in July, 1916.

### DEATHS IN THE SERVICES.

Deputy Surgeon-General A. J. Ferguson, on March 7th at Weymouth, in his eightieth year. He received his first commission in 1858 and took part in the Afghan War of 1878-80 (mentioned in despatches and medal). He retired on half-pay in 1885.

**THE CORNWALL NAVAL HOSPITAL.**—The first annual report of the Royal Naval Auxiliary Hospital, Truro, which has been recently issued, shows that during 1916 1186 patients were admitted, and of that number 1024 were discharged for duty. The average number of occupied beds was 158; the average number of days in hospital was 39. The financial statement was satisfactory. Fleet-Surgeon Andrews is in medical charge of the institution, the honorary surgeons being Mr. L. C. Panting and Dr. H. C. Sharp. Dr. K. C. Chetwood-Aiken is honorary ophthalmic surgeon and Mr. H. M. Sutton is the medical officer.

## Correspondence.

*"Audi alteram partem."*

### THE CLOSURE OF COLOSTOMY OPENINGS.

*To the Editor of THE LANCET.*

SIR.—Mr. P. Lockhart-Mummery's contribution to this subject in your issue of March 10th calls for comment. His assertion that "a temporary colostomy is a rare condition in civilian practice" is far from being correct. The general recognition on the part of surgeons that obstruction in the large intestine is best dealt with by a proximal colostomy, to be followed in suitable cases, after an interval, by resection of the offending segment of the bowel, and, later still, by closure of the artificial anus, has produced many such operations. Moreover, the established value of the three-fold operation in cases of obstruction has led many surgeons to adopt the procedure as a routine practice in dealing with cancerous growths of the colon where obstruction is not a feature of the case. My chief object, however, in writing this letter is to call attention to a method of closing colostomy openings which I have adopted in upwards of 30 consecutive cases without a single fatality and with uniform success. The method was fully described by the late Greig Smith in his work on "Abdominal Surgery," vol. ii., p. 727.

The aim of the operation is to close the artificial anus without opening the general peritoneal cavity, and this is managed by detaching from the parietes, all round the anus, sufficient peritoneum to permit of delivery of the gut through a parietal incision without separating it from its adhesions to the peritoneum. The opening is temporarily closed by a gauze plug. Incisions, each  $1\frac{1}{2}$  inches in length, are made above and below it through the skin and abdominal muscles down to the parietal peritoneum. They begin immediately outside the junction of the skin and mucous membrane, and may be either vertical or oblique. A finger is introduced and the muscles are gently raised from the underlying peritoneum on either side of the incisions. It is best to begin the separation at the end of the incision farthest from the anus because there are no adhesions here. Next the skin all around is divided with a scalpel one-eighth of an inch from its circumference; then with scissors the muscles are separated, taking care not to puncture the underlying peritoneum. When this has been done the colostomy opening and the adjacent colon can be lifted out of the wound to almost any desired extent. Gauze is packed in the wound all around the protruding anus and its muco-cutaneous margin is cut off. The refreshed edges of the anus are now united transversely to the long axis of the bowel by a suture of fine catgut, which should take a firm grip of both the musculo-peritoneal and mucous coats. The gauze packing and the surgeon's gloves are changed, and the area thoroughly cleansed with a stream of warm saline solution. A superimposed suture of fine silk is passed through the peritoneal and muscular coats, so as to bury the catgut suture. The loop of bowel is then pushed inside the abdominal wall, and the peritoneal wound closed by closely placed through-and-through silk-worm-gut sutures. A small rubber drain-tube is placed in the centre of the wound and the usual dressings applied. The drain-tube is removed at the end of 48 hours, and in the vast majority of cases primary union results. Very occasionally a small faecal fistula appears at the end of a week, but in every such case closure follows after a short interval. Every now and then the parietal peritoneum has been punctured, but in no case has this made any difference. Inasmuch as there is nearly always a bridge of healthy bowel wall, varying from one-third to two-thirds of its circumference, on the mesenteric side, there is not the slightest risk of a stricture forming at the site of operation.

Greig Smith's operation is applicable to the vast majority of colostomy openings, including faecal fistulae from gangrenous umbilical hernia and those following operations for gangrenous appendicitis. In view of its safety and the uniform success following its adoption, I may be pardoned for expressing the conviction that enterotomes and similar contrivances should be relegated to surgical instrument museums. Two of my most recent cases were soldiers who had been shot in the abdomen. They were operated on a

few hours later by Captain J. Frazer, who in both cases, after suturing multiple wounds of the intestines, established an artificial anus in the transverse colon. In both the colostomy opening concerned quite one-half of the circumference of the colon. Both healed without suppuration. Mr. Paul Bernard Roth in your issue for to-day describes what he calls "a simpler method of closing colostomy openings." Admitting its ingenuity, one is bound to recognise that it involves the resection of a segment of the colon *within* the peritoneal cavity. This procedure, owing to the relatively septic condition of the mucous membrane and the poor blood-supply as compared with the small intestine is, when every precaution has been taken, one involving a very definite risk to life, and with Greig Smith's operation as an alternative I do not hesitate to say that, in my opinion, it is quite unjustifiable.

Just a word as to after-treatment. Mr. Lockhart-Mummery recommends that the bowels should be made to act daily after the operation. Surely this is bad advice. Here, more than elsewhere, one of the essentials to good healing is rest. Care should be taken to have the bowels well emptied before operation, but thereafter for a few days the less peristalsis the better. As a matter of fact I never give an aperient in these cases until the end of the first week.

I am, Sir, yours faithfully,

SINCLAIR WHITE,  
March 17th, 1917. Professor of Surgery, Sheffield University.

*To the Editor of THE LANCET.*

SIR.—In your issue of March 10th Mr. P. Lockhart-Mummery describes two methods of closing temporary colostomy openings. He recommends the use of the enterotome or alternatively direct suture after intraperitoneal resection. Of the enterotome I know nothing. There is little temptation to employ a method which relies for success on imperfectly regulated pressure-necrosis when better results can be obtained by measures equally safe and more precise.

I have closed a number of these openings with unqualified success both in military and civil practice and have never found it necessary to subject a patient to whatever risk may be attached to intraperitoneal resection or suture. The mode of procedure adopted has been direct extraperitoneal suture with preliminary use of the drainage-tube device of Mitchell Banks. The method is described in Greig Smith's "Abdominal Surgery," 1897, vol. ii. The description is so full and the modifications introduced in practice so trivial that nothing further than the reference is required. It would appear that this extraperitoneal method is neither so well known nor so widely practised as its merits deserve. It can confidently be recommended as of universal application, absolutely safe, and absolutely certain.

I am, Sir, yours faithfully,

Harley-street, W., March 18th, 1917. PERCIVAL P. COLE.

### RATIONS GUIDE: FOOD REQUIREMENTS OF CHILDREN.

*To the Editor of THE LANCET.*

SIR.—In the admirable series of recommendations on rationing and "How to Save Food" recently issued by the Food Controller, there are certain recommendations made with regard to the diet of children that appear to call for revision. The recommendations of the Food Controller are based on the following statement: "Children need plentiful food. A child of 8 needs half as much as a grown-up; a girl of 12 three-fifths as much; a girl of 16 needs as much as her mother, and a boy of 16 may eat as much as his father."

I am aware that this represents the teaching of standard text-books on the subject, though I have never been able to ascertain the exact data on which the original recommendation by Atwater was founded. I venture to think, however, that this teaching is wrong and is to be deprecated as a guide at the present time. My opinion is based both on practical observation and special investigation. The food requirements of a healthy schoolboy, say of 12 years, can be fairly accurately gauged from observation and a comparison with those of his parents on the same régime. If this test be applied, it can, I think, safely be said that the average boy of 12, in a household of the professional class, eats as much as his father. Corroborative information is obtained

from the laboratory standpoint. Some time ago I made a detailed study of the actual amount consumed by healthy children in a series of medical families, every precaution being taken to ascertain the exact amount of food consumed. The ages of the children ranged from 4 to 6 years. The result showed a daily average of: Protein, 71 grms.; fat, 67 grms.; carbohydrates, 198 grms.; the total calories amounting to 1725. The supply of protein—the main food element in the dietary of children—consumed by a child of 6 years and under is shown to be greater than that allowed for by the Food Controller for a boy of 12.

Fully grown subjects may with safety and positive advantage to health accept the standard laid down for the average adult by the Food Controller. It is, however, not advisable to restrict the feeding of children to the extent indicated in the Food Controller's recommendations. A wise economy in regard to the feeding of children should be looked for in the selection of foodstuffs rather than in a reduction of quantity below the pre-war standard.

I am, Sir, yours faithfully,

Edinburgh, March 17th, 1917.

CHALMERS WATSON, M.D.

## THE DIFFERENTIATION OF HEART MURMURS.

To the Editor of THE LANCET.

SIR.—I fail to understand why Professor David Drummond, in his letter in your issue of Feb. 17th, should think it strange my questioning his remarks on "The Differentiation of Heart Murmurs." In the whole range of his cases I note he gives no post-mortem results, and in the absence of such surely our opinions are apt to be wide of the mark. May I remind Professor Drummond of a very interesting article with post-mortem results in THE LANCET, 1895, vol. ii., by Dr. A. G. Phear, quoting Dr. Ringe's cases. Professor Drummond apparently considers that murmurs which disappear are due to vibrations of the chest wall. In answer to this, I think Dr. Theodore Fisher rightly observes, "It is difficult quite to gather his meaning." For, as Dr. Fisher says: "The chest wall being the medium which, through the stethoscope, conveys murmurs to our ears must vibrate in all cases, but neither with functional nor organic disease can murmurs, it seems to me, originate in the chest wall." I trust I am not unduly trespassing on your valuable space in prolonging this discussion, and I would like to assure Professor Drummond I am more anxious to learn than in any way to put forward my own ideas.

I am, Sir, yours faithfully,

Bournemouth, March 19th, 1917.

A. KINSEY-MORGAN.

## ACUTE DILATATION OF THE STOMACH FOLLOWING GASTRO-ENTEROSTOMY.

To the Editor of THE LANCET.

SIR.—The question as to the cause of acute dilatation of the stomach following gastro-enterostomy raised by Dr. F. Godfrey in THE LANCET of March 3rd is a very interesting one, and is my excuse for publishing the following experience.

About six years ago I performed posterior gastro-enterostomy on a man aged 40 years, for duodenal ulcer and as there was a suspicion of gall-bladder trouble, the incision was made about one and a half inches to the right of the mid-line. The patient, unfortunately for the procedure, had a well-developed abdominal wall, with powerful muscles which no effort of the anaesthetist could relax; and it was found when the stomach and jejunum were drawn out and approximated for suture that there was a little tension which necessitated a slightly firmer grip of the clamps than is customary. The operation was completed, following the Moynihan technique. All went well until the fourth day, when the patient vomited slightly and complained of discomfort in the abdomen. On examination I found a distended splashing stomach. A tube was passed and about four pints of watery fluid siphoned off, which gave marked relief. Next day the procedure had to be repeated, with a similar result. The patient now looked ill and shrunken, although he was absorbing a large quantity of saline per rectum, and fearing a kink or other cause of obstruction I decided to reopen the abdomen. On doing so I found the anastomosis perfect, but the intestine on either side for a few inches was contracted, rigid, and friable, it was much discoloured and the coats

thickened by inflammation. The stomach near the anastomosis was similarly affected. It was obvious that peristalsis in this area was quite impossible and the condition of the patient was thus easily accounted for. I have no doubt the state of the intestine and stomach was caused by the clamp pressure and possibly by tension on the mesentery during the operation. The abdomen was closed and the stomach-tube passed frequently to prevent accumulation until the intestine recovered tone, which it did about the eighth day. The patient then quickly recovered.

I saw him about a year afterwards; he was in excellent health and joined the Army at the beginning of the war. I have no doubt the stomach-tube saved his life. I have not heard or read of clamp pressure as a cause of atony, but I am convinced that this case is not unique, and it helps to explain at least some of the cases where vomiting occurs on the third or fourth day and the patients recover after the free use of the stomach-tube.

I am, Sir, yours faithfully,

Clonmel, March 14th, 1917.

P. J. BYRNE, F.R.C.S. Ire.

## TUBERCULOSIS AND THE WAR.

To the Editor of THE LANCET.

SIR.—After reading Dr. H. A. Ellis's letter on the above subject in THE LANCET of March 10th it occurred to me that it gave an explanation of the uselessness of treating patients in sanatoriums, for it would seem that a sanatorium is regarded by many as a place for throw-outs from dispensaries. If, of course, this is the intention of these institutions it is useless to deplore the absence of early cases for treatment, as the dispensary would appear to be a very efficient sieve, preventing the treatment of pulmonary tuberculosis until the patients were chronic, and probably chronics which had become acute. It is quite clear to me that if a man is unable to do anything but light work he should be sent to a sanatorium at once in order that he may be permanently cured. I would suggest, therefore, it might be a good plan to commence sending cases in Class I. at once, without the intervention of a dispensary, to properly conducted sanatoriums. I have never here found the least difficulty in treating discharged soldiers for periods of five months: my only difficulty is that many have been kept out when in what may be called Class I., with deplorable results. The least we can do for our soldiers is to provide them with real sanatorium treatment at a stage when it is possible to cure them permanently.

I quite agree with your annotation that the general practitioner should be the chief factor in looking after the tuberculous; whether the visits of a tuberculosis officer to practitioners will do any good will, of course, depend on the capacity and training of that gentleman.

I am, Sir, yours faithfully,

EDWARD E. PREST.

Ayrshire Sanatorium, New Cumnock, March 12th, 1917.

## AN APOLOGY.

To the Editor of THE LANCET.

SIR.—We have the concurrence of the solicitors to the Evening Standard in requesting you to give space in THE LANCET to the following expression of explanation and apology to Dr. Henry Dutch which appeared in the issue of the Evening Standard dated March 2nd:—

### THE WHITE CITY CASE.

An Explanation and an Apology to Dr. Dutch.

Our attention has been called to an unfortunate inaccuracy in the report of these proceedings appearing in our issue of February 27th. From our report it would appear as though Mr. Muir said that Dr. Dutch had told Sauge "to drop the Sergeant-Major a quid."

As a matter of fact, Mr. Muir, in making the statement quoted above, was referring to quite a different person and made no aspersion whatever upon Dr. Dutch. We much regret the inaccuracy in our report, and we are pleased to take the earliest opportunity of correcting any misapprehension and express our unqualified apology to Dr. Dutch for any annoyance caused to him.

We shall therefore esteem it a favour if you will publish this letter in your next issue.

We are, Sir, yours obediently,

HEMPSONS,

Bedford House, 33, Henrietta-street. Solicitors for Dr. Henry Dutch. Strand, March 15th, 1917.

## Obituary.

### FREDERICK W. HALLIDAY, M.R.C.S., L.R.C.P. LOND.

THE profession in Leeds is the poorer in many ways by the untimely death of Mr. F. W. Halliday, which occurred on March 5th at his house in Wortley, the village in, or near, which he was born, and in which almost the whole of his professional life was passed. He was educated at the Medical School in Leeds, and soon after qualifying he entered the service of the Peninsular and Oriental Steam Navigation Company, and served as ship surgeon on most of their routes in the East, retaining lively memories of India and Japan for the rest of his life. He had a widespread general practice, which he conducted with success; his kindness and courtesy were unfailing to all his patients—rich and poor alike.

During the last few months of his life he acted as medical officer to a Filling Factory, where he had the medical supervision of some 14,000 female operatives, and here his work was of the same thorough and considerate character that he displayed in private practice, and it is not too much to say that he secured the affectionate regard of the workers as well of the managers of the huge establishment. His personal friends have learned of his death in the prime of life with a great sense of loss.

### WALTER DURET AUBIN, M.B., C.M. EDIN.

LIEUTENANT-BAILIFF AND JURAT, ROYAL COURT OF JERSEY.

THE death is announced of Dr. W. Duret Aubin, in his sixty-ninth year, at his residence in Jersey on March 9th.

After receiving his early education at the Lycée of Coutances, Duret Aubin entered the medical school of Edinburgh University, where he was known as a hard-working and successful student. He graduated in 1870, just at the time the Franco-Prussian War broke out, and volunteered for service in France in the International Red Cross Society. At the close of hostilities he was awarded the Cross of that society and, later, the commemorative medal of the French Republic. Returning to Jersey, Duret Aubin settled down in practice at St. Heliers, his personal qualities soon obtaining for him an extensive general practice. At this time he entered the Island Militia as an assistant surgeon, eventually attaining the rank of Surgeon Lieutenant-Colonel. In 1895 he was elected as a Deputy for St. Heller in the island legislature and did much useful work in that position. He was instrumental in placing the local Pharmacy Act on the Statute Book and he piloted through the States other measures for the good of the community. Patriotic and full of enthusiasm at heart, he was nevertheless a courteous and conciliatory debater. In 1899 he was called to the judicial bench, manifesting there the industry, patience, and critical acumen which had marked his previous career. By the time he had risen to be deputy chief magistrate (Lieutenant-Bailiff) he had gradually relinquished medical practice, with a view of working in his public capacity, but his other activities were numerous. For many years he was President of the Hospital Committee, as also of the Jersey Boys' Home, while many local societies found in him a friend and supporter. In all his public work Durat Aubin was guided by a deep sense of duty, and in this connexion a friend of his writes: "It has sometimes been urged that medical men, as a class, do not take their proper share in public work. As a life-long friend of Durat Aubin, I may be permitted to adduce him as a conspicuous instance of one to whom this did not apply."

Dr. Duret Aubin was twice married. He leaves a widow, two daughters, and a son.

THE name of Dr. Artur Pappenheim is to be added to the already considerable list of distinguished German medical men who have fallen a victim to typhus. Dr. Pappenheim was lecturer on diseases of the blood in Berlin University and editor of *Folia hematologica*. He was in his forty-seventh year.

THE LATE MR. ISAAC USHER.—One of the oldest and best-known practitioners in co. Dublin, Mr. Isaac W. Usher, recently lost his life in a tragic manner, being knocked down in the street by a motor-car. He was nearly 80 years of age, and had been a highly respected medical practitioner.

## The War.

### THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

#### Killed.

Lieut. T. W. Jones, R.A.M.C., attached Northumberland Fusiliers, received his medical education at the University of Liverpool and qualified in 1908. He had held appointments at the Northern Hospital, at the Maternity Hospital, and at the City Hospital, Liverpool, and at the time of joining up was medical officer of health, school medical officer, and medical superintendent of the Fever Hospital, Wrexham.

Lieut. A. I. Miller, R.A.M.C., attached Royal Field Artillery, was educated at Edinburgh University and qualified in 1905. Prior to joining the R.A.M.C. in September last he was in practice at Stourbridge, Worcestershire.

#### Died of Wounds.

Lieut.-Col. M. L. Williams, Australian Army Medical Corps, qualified M.B. at Melbourne in 1908, and was in practice at Bendigo, Victoria, prior to joining the Expeditionary Force.

Lieut. J. M. Hammond, R.A.M.C., was a medical student at St. Bartholomew's Hospital, London, and qualified in 1908. He had held appointments at the West London and at St. George's Hospitals, and was in practice at Bournemouth when he joined the R.A.M.C. in July last.

#### Died.

Lieut. F. G. Heard, R.A.M.C., was educated at Edinburgh University and qualified in 1889. He had held appointments at the Free Dispensary, Edinburgh, and at the Rotunda Hospital, Dublin, and at the time of joining the R.A.M.C. was in practice at Undercliffe, near Bradford, where he also held public appointments.

#### Wounded.

Capt. S. J. Linzell, R.A.M.C.

Capt. G. D. Newton, R.A.M.C., attached Royal Lancaster Regiment.

Lieut. A. Y. Dabholkar, I.M.S.

Lieut. E. R. Daboo, I.M.S.

*Previously reported believed taken Prisoner at Kut-el-Amara, now reported Prisoner of War in Turkish Hands.*

Capt. R. C. Clifford, I.M.S.

### DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

Private J. M. Furnivall, Duke of Cornwall's Light Infantry, youngest son of Dr. H. W. Furnivall, of Woodbury, Devon.

Lieut. R. N. Irwin, Gloucester Regiment, younger son of Dr. S. Irwin, of Olveston, Gloucester.

Second Lieut. C. F. Umney, Dorset Regiment, elder son of Dr. W. F. Umney, of Sydenham, Kent.

Second Lieut. H. G. Downes, Royal Engineers, only son of Dr. H. Downes, of Hornsey, London.

### THE HONOURS LIST.

The following awards to medical officers in connexion with the operations in Mesopotamia are announced:—

#### Distinguished Service Order.

Capt. Allan Watson, R.A.M.C.

#### Military Cross.

Temp. Lieut. A. Y. Dabholkar, I.M.S.

Temp. Capt. J. Low, R.A.M.C.

Temp. Capt. C. O'Brien, R.A.M.C.

### MENTIONED IN DESPATCHES.

The name of the following medical officer should be added to the names published in THE LANCET of Nov. 13th, 1915, in connexion with operations in the Dardanelles:—

Capt. M. F. Reaney, I.M.S. (deceased).

HONITON (DEVON) V.A.D. HOSPITAL.—The mayor of Honiton recently opened a new "open-air ward" containing 30 beds, which has been added to the V.A.D. Hospital. The institution now contains 50 beds.

**CONFERENCE SUMMONED BY MR. NEVILLE CHAMBERLAIN.**

The Conference summoned by Mr. Neville Chamberlain, Director-General of National Service, to consider the organisation of the medical profession with a view to meeting the needs of the military and civil population in existing circumstances, was opened on March 14th and sat on March 15th also, under the chairmanship of Sir Donald MacAlister. We published last week a list of the representatives of the Central Medical War Committee, the Scottish Medical Service Emergency Committee, and the Committee of Reference of the English Royal Colleges, the three bodies through whom the Services have drawn their supply of medical officers for the war, who were present at the conference. The subjects under discussion were: First, the question of whether service to be given by members of the medical profession was to be voluntary or compulsory; secondly, what arrangements should be made for the collection and distribution of fees or other form of remuneration in cases where doctors leave their own practices or take on the practices of others; thirdly, what arrangements should be made: (a) centrally and (b) locally, for redistribution of medical men; and fourthly, what should be the relations between any central executive or advisory body representing the profession and the Department of National Service.

The report of the representatives of the Central Medical War Committee upon the proceedings of the Conference was received by that Committee during the week, but no set discussion followed, it being understood that the views of the Conference were largely those already expressed in the published resolutions of the Committee.

We are precluded from suggesting more definitely what actual course will be pursued, or what form any necessary legislation may take, until the Director-General of National Service is able to communicate the view of his Department. But as far as the demand on the medical profession is concerned, a largely increased number of medical officers is now stated to be required for the Army; and, as the War Office contemplates not being able to keep back any officers of military age from general service, it is clear that many openings for those above that age may be created.

**THE MOBILISATION OF THE MEDICAL PROFESSION.**

A meeting of registered medical practitioners in Glasgow and the West of Scotland will be held in the Faculty Hall, St. Vincent-street, Glasgow, on Tuesday next, March 27th, at 4.30 P.M., when the opinion of the medical profession will be invited upon the following points: (a) Does the meeting approve of the principle of the immediate and compulsory mobilisation of the whole nation (due regard being paid to age, training, and circumstances), to secure the successful and rapid conclusion of the war? (b) Does the meeting approve of the medical profession being so mobilised, in advance of the community? And (c) if the medical profession is to be mobilised, is the meeting satisfied with the arrangements which already exist, centrally and locally, for the redistribution of medical men and for administrative purposes generally?

**EDUCATIONAL FACILITIES FOR BRITISH PRISONERS OF WAR.**

At a representative and largely attended Conference of Examining Bodies in Great Britain held on March 15th at the Board of Education under the presidency of Mr. A. T. Davies, C.B., chairman of the British Prisoners of War Book Scheme (Educational), it was unanimously decided, on the motion of Sir Edward Busk, Chairman of Convocation of the University of London, to approve proposals for the recognition of the studies pursued by prisoners during their internment. Steps are being taken to give effect to these proposals, and various examining bodies, including most of the universities, have already intimated their willingness to recognise work done and examinations passed in the camps and to extend to the men, on their return, facilities for sitting for examinations under conditions which will take account both of their special circumstances and their needs. A message was read from the President of the Board of Education, in which Mr. Fisher expressed sympathy with the objects of the Conference and his belief that the result of its efforts would prove a great encouragement to the men to use wisely

and well the time of their captivity, and, further, would be of material assistance to them on their return to this country. It is intended that the decision arrived at shall be communicated as soon as possible as "a message of encouragement and hope" to the various internment camps in enemy and neutral countries. Meantime it was suggested that friends and relatives of student prisoners might do them a service if, when writing to them, they will draw their attention to the steps in this connexion which are being taken on their behalf.

**RED CROSS WORK IN THE COUNTY OF LONDON.**—In his report for January the county secretary of the British Red Cross Society states that a lecture given by Colonel James Cantlie to women conductors of the London General Omnibus Company was greatly appreciated by them, and that the company have made arrangements for a regular course of lectures to their women employees in first-aid work. A new division of the Red Cross Society has been formed at Southwark. Mention is made of the good work done by different detachments at the recent explosion in a munition factory. In the examinations held during the month 186 candidates passed and 26 failed in first-aid, while 82 passed and 5 failed in home nursing.—In the February report all members of the V.A.D. are exhorted to consider themselves as recruiting agents and to enrol as many members as possible. The difficulty in supplying an adequate number of lecturers for first-aid and home-nursing courses is to be met by asking those desirous of qualifying for Red Cross work to attend lectures at the College of Ambulance (3, Vere-street), where full facilities are afforded. In the February examination 131 candidates passed and 21 failed in first-aid, 93 passed and 9 failed in home nursing, while all of 3 passed in hygiene. The total number of candidates for examination under the central examination scheme inaugurated in July, 1916, was 1324 up to the end of last year, the percentage of passes being 88.

**FRENCH CONSERVATIVE SURGERY.**—Dr. Louis Menciére, a paper by whom on the treatment of gas gangrene when he was *médecin-chef* of the Hôpital de la Compassion, Rheims, was published in THE LANCASTER of Sept. 11th, 1915, has just been made Chevalier of the Legion of Honour and *chirurgien-chef* at the Grand Palais Hospital in Paris. His mission is to continue his scientific researches and to popularise his method of treatment of war wounds. Professor Sartory, who occupies the chair of chemistry and bacteriology of the Faculty of Medicine of Nancy, is associated with him, and the Army laboratory at the Invalides has been placed at their disposal. Dr. Menciére's well-earned promotion is a direct result of the success of his conservative methods in saving numberless amputations, which won the approval of General Nimier, *médecin-inspecteur* of the VI. Army.

**WAR DRAWINGS.**—Mr. Muirhead Bone's recent drawings in France are being reproduced by authority of the War Office under the title of "The Western Front." In addition to this publication a selection of drawings will be reproduced on a larger scale (20 in. x 15 in.) to give full effect to the artist's work. "War Drawings" will consist of a series of parts each containing ten illustrations. The drawings will appear as nearly as possible in facsimile, printed in one, two, or more colours according to the character of the originals. It will be possible to obtain separate plates from this publication.

**HOT WATER FOR THE TROOPS IN THE FIELD.**—An illustrated pamphlet issued by the British Berna Motor Lorries, Limited (Waterloo-place, S.W. 1), gives details of the type of bath caravan manufactured by them, one of which has been presented by the Wounded Allies Relief Committee to the Belgian Army. The caravan carries 12 enamelled steel baths and a boiler capable of yielding hourly 50 to 60 baths of 20 gallons each at a temperature of 110° F. More than 500 men can thus within a period of 12 hours enjoy a separate hot bath under conditions of comfort at a cost of approximately 1d. per bath. The caravan provides accommodation for two men, while at one end are drying closets and at the other disinfecting chambers. The bathing-tents or huts are formed of canvas sheeting attached to the edge of the caravan roof on the one side and to light poles on the other, the sides being also covered in with canvas:

**BATH MILITARY HOSPITAL.**—Accommodation is being provided at the Bath Military Hospital for 500 additional patients.

**MILITARY HOSPITAL FOR CORNWALL.**—The beautiful house and grounds of Tregeanna, Camborne, are being fitted up as an auxiliary military hospital. Accommodation will be provided for 50 beds.

**AMERICAN WOMEN'S HOSPITAL FOR OFFICERS.**—This hospital, which owes its origin to the American Women's War Relief Fund, was opened on Wednesday, at 98 and 99, Lancaster-gate, London, by the United States Ambassador. The hospital provides 45 beds under a resident medical officer, Dr. R. H. Browne-Carthew. The same fund has provided the War Hospital of 250 beds at Paignton, Devon.

**A HOSPITAL EXTENSION AT HOVE.**—An addition has been made to the already numerous military hospitals and Red Cross institutions at Hove by the opening in Palmeira-square of an institution for the treatment of paralysed and nerve-affected soldiers. The new hospital is really an extension of the neurological department of the 2nd Eastern General Hospital. It is well fitted up for the reception of 25 patients, and has been called after the founder, Lady George Nevill.

**TRAINING OF DISABLED SOLDIERS**—Replying to questions in the House of Commons on March 19th, Sir A. Bosawen, Parliamentary Secretary to the Pensions Ministry, stated that every endeavour was being made to put the treatment and training of disabled men on a systematic basis in every part of the Kingdom. A joint committee had already been formed in Lancashire for the purpose of pooling facilities, and a similar committee was just being set up in Yorkshire. If proper institutions were not available the Ministry would not shrink from founding new ones. He laid special emphasis on the proposal, constituting a new principle, that pensions would not be reduced as earning capacity increased.

## Medical News.

**UNIVERSITY OF LIVERPOOL.**—At examinations held recently the following candidates were successful:—

**M.B., Ch.B.**—Second Examination, Part B: Mary H. Wild. Final Examination, Part I.: L. Farris, P. E. Gorst, G. R. James (distinction in Pathology), and V. E. Jones. Part II.: W. M. Jones (distinction in Forensic Medicine and Toxicology) and Public Health), and F. A. Prosser. Part III.: E. S. Stubbs (first-class honours and distinction in Obstetric Surgery), I. J. Lipkin (second-class honours and distinction in Obstetrics), P. B. Pinkerton (second-class honours and distinction in Obstetrics), M. Azer, Constance M. Edwards, A. J. B. Griffin, Ruby E. McBirnie, R. Nixon, C. V. Pearson, and R. C. Watts.

**Licentiatehip in Dental Surgery.**—Second Examination, Part I.: I. W. Brown, C. L. Wade, and H. G. Watkin. Part II.: C. L. Wade, H. G. Watkin, and E. H. Williams. Third Examination, Part I.: E. W. H. Owen, F. J. Parle, and E. O. Roberts. Part II.: H. Brown, R. B. Ginsberg, and F. Lockwood. Final Examination: A. Hesselberg and P. Moses.

**ROYAL COLLEGE OF SURGEONS OF EDINBURGH.**—At the recent Dental Examinations just concluded the following candidates passed the First Dental Examination:—

Andrew John Molynaux and Egbert John Charles Steyn.

The following passed in the subject of Chemistry and Physics:—

Donald Skinner and George Izett Alexander.

The following passed the Final Examination and were granted the diploma L.D.S., R.C.S. Edin.:—

Petrus Jacobus Hugo le Roux, South Africa; William Graham Bowie, Edinburgh; Leonard Walter Blazey, London; Ulrich Oscar Gottlieb Reinecke, Orange Free State; John McCurdy, Co. Antrim; and Meindert de Villiers, South Africa.

**ROYAL MEDICAL BENEVOLENT FUND.**—The annual general meeting of the supporters of the Fund took place on March 13th, at 11, Chandos-street, W., Mr. J. H. Morgan being in the chair. It was announced that Sir John Tweedy had resigned the Presidency, which he had held for 10 years, during which had occurred both the incorporation of the Fund and the establishment of the Guild. The thanks of the Fund were given to him for his services, and Dr. Samuel West was elected President in his place, after a service of 22 years as honorary treasurer. To Dr. West the Fund is indebted for the introduction of the present system of

accounts, while during his office the output in charity has doubled, the invested property has risen from £52,000 in 1896 to over £102,000, and the number of annuities has risen from 108 to 161. Colonel Charters J. Symonds was appointed treasurer and Dr. G. Newton Pitt re-elected honorary secretary; and the following new members were added to the committee: Dr. J. Fawcett, Dr. Leonard Guthrie, Dr. W. S. Colman, and Mr. Guy Elliston. Cordial thanks were passed to the honorary auditors, Messrs. Deloitte, Plender, and Griffiths, and to the Press, and especially to the editors of the *British Medical Journal* and *THE LANCET* and to Mr. Guy Elliston of the British Medical Association. The annual report showed that the total subscriptions and donations amounted to £2067, a decrease of £176 compared with last year. The amount distributed in relief was £2503, the excess being made up out of the reserves. The annuity department expended £3119, £91 more than last year, and the number of annuitants was increased by 12. The usual Christmas gift of £1 was sent to each annuitant, and a similar gift to the most deserving grantees, the two grants amounting to £270. The chief event of the year was the War Emergency Appeal, the object of which was to assist medical men, on their return from the war, to recover their position which had suffered by their absence. About £4000 were received, but this is far less than will be required for the object in view, and the public as well as the profession is strongly urged to support this Fund, which is the only one of its kind for the medical profession. £6100 had been invested in the War Loans, part being by the transfer of investments, but £2100 was new money. The annual report of the Guild was ordered to be published with that of the Fund.

At the meeting of the Committee held the same day 20 cases were considered, and £277 4s. voted to 17 of the applicants. The following is a summary of some of the cases received:—

Widow, aged 49, of L.R.C.P. Irel. who practised at Great Yarmouth and died in 1915. Was left practically without means, and owing to ill-health is unable to earn a living. At present staying with friends, who cannot continue to help her permanently. Voted £6 in six instalments.—Widow, aged 29, of M.B. Lond. who was a Medical Missionary in China and died in June, 1916. Applicant left with two children, ages 2 and 4, and only £35 per annum. Another charity has promised £20 per annum. Applicant wants some help to provide training for herself, so that she will be able to earn a living. Voted £2, and referred to the Guild.—Daughter, aged 50, of M.D. Dub. who practised at Cambridge and died in 1904. Applicant was a teacher in a boarding school, and in 1913 took over the school, but the venture has not been a success, owing mainly to bad health and bad eyesight, which is gradually getting worse, having lost the sight of one eye. Is now in great financial difficulty. Voted £10.—Widow, aged 62, of L.R.C.P. Edin. who practised at Wigan and died in 1913. Endeavours to make a living by letting rooms in the summer, but last year was not successful. Only son joined the Army and the allowance of 9s. 3d. per week is all she has to definitely depend upon. There are a few small debts still owing from her husband's practice, but these are almost all collected now. Wants help towards her rent. Voted £10.—Wife, aged 38, of M.R.C.S. Eng. who practised at Bournemouth, but is now in an asylum. Applicant has no means and is suffering from advanced tuberculosis. Her three children are provided for at present. She has a little help from other charities, but not sufficient to meet her requirements. Relieved twice, £37 10s. Voted £18 in 12 instalments.—Widow, aged 68, of M.B. Edin. who practised at Bolton and died in 1905. Only certain income £9 5s. The bulk of her money was lost through a defrauding trustee. Has three children, two married and unable to help, and one son who lives at home, but only earns £1 per week. Relieved once, £12. Voted £12 in 12 instalments.—Daughter, aged 56, of M.R.C.S. Eng. who practised at Manchester and died in 1896. Owing to ill-health applicant had to give up her work as a clerk. Only income a pension from her late employers of 8s. per week. Relieved twice, £26. Voted £15 in 12 instalments.—Wife, aged 51, of L.R.C.P. Irel. who practised at Chatham, and left his wife some years ago, with three children to bring up. The children are now getting on well, the eldest daughter having recently taken a situation, but not able to help much, as she is away from home. The eldest son is in the Army and the youngest at Epsom College. Applicant unable to work owing to eye trouble. Relieved four times, £38, and helped by the Guild. Voted £12 in 12 instalments.—Daughter, aged 53, of M.R.C.S. Eng. who practised in London, and died in 1895. Applicant's health is very indifferent, and although she has tried various kinds of employment her health will not permit her to continue. At present staying at a home of rest. Relieved five times, £63. Voted £12 in 12 instalments.—Widow, aged 62, of L.R.C.P. Edin. who practised at Dumfries, and died in 1909. Applicant was left with four children, two of whom are now in the Army, and the youngest daughter only earning 23s. a week and not living at home. Applicant unable to work owing to ill-health. Relieved eight times, £80. Voted £12 in 12 instalments.—L.R.C.P. Lond. and L.S.A. Lond., aged 89 (married, his wife 83), who practised at Wandsworth. Owing to age not able to do much work. Some years ago lost practically all his practice through the removal of a large railway works from near his house, and from which most of his practice came. This, with the coming of the National Insurance Act, ruined his practice. In great financial difficulties. Relieved once, in 1913, £12. Voted £26 in 12 instalments.—Widow, aged 48, of M.B. Edin. who practised at Glasgow and died in 1912. Applicant was left totally unprovided for, with seven children. The two eldest are now married, two others are in the Army, one daughter a clerk earning 10s. per week, and the others are at school. Income from other charities £22, and from children £41 12s. Relieved five times, £92. Voted £20 in 12 instalments.—Daughter, aged 50, of M.D. Glasg. who practised at Hawtry and died in 1872. Applicant lives in own house. Endeavours to make a living by taking in paying guests, but as

the lives on the East Coast has not been successful since the war commenced. Relieved twice, £20. Voted £10 in two instalments.—Widow, aged 53, of M.B. Aberd. who practised at Belfast and Dublin and died in 1913. Was left unprovided for with four children. The eldest son was in his second year as a medical student when the war broke out and had to join the Army. He has been wounded and is now invalided out of the service and is continuing his medical studies. The other children only earning very little. Relieved once, £5. Voted £15 from the War Emergency Fund.—Widow, aged 63, of L.R.C.P. Irel. who practised in London and died in 1916. Her husband was for some years a pensioner of the Fund and the applicant was left quite unprovided for and makes living by letting rooms. Relieved twice, £14. Voted £15 in 12 instalments.—Widow, aged 59, of M.D. Edin. who practised in Cumberland and died in 1903. Endeavours to make a living by taking in boarders, but does not get sufficient. Has four children, all married and unable to help. Relieved ten times, £120. Voted £15 in 12 instalments.

Subscriptions may be sent to Dr. Samuel West at 11, Chandos-street, Cavendish-square, London, W., who will act temporarily as honorary treasurer during the absence on duty of Colonel Charters Symonds.

**RED CROSS PHYSICAL CLINIC.**—At the Red Cross Physical Clinic for Wounded and Disabled Officers (26, Great Portland-st., W.1) on Thursday and Friday next, March 29th and 30th, a short account of the methods of treatment and of the measuring instruments employed in testing functional efficiency will be given on both days at 4 P.M. Admission will be free to members of the medical profession.

**ROYAL ABERDEEN HOSPITAL FOR SICK CHILDREN.**—The fortieth annual report of this hospital shows a total of 1871 cases treated during the year, 759 as in-patients and 1112 as out-patients. Of these 759 in-patients 590 were discharged as cured, 50 died, and 3 improved. The work of the hospital has again been carried out at Keppelstone. The open-air ward, accommodating 26 cases, opened in May, 1916, has proved an unqualified success. The gross ordinary expenditure has exceeded the ordinary income for the year by £338.

**CENTRAL MIDWIVES BOARD.**—Special meetings of the Central Midwives Board were held at Queen Anne's Gate Buildings, Westminster, on March 13th and 14th, with Sir Francis H. Champneys in the chair. A number of midwives were struck off the Roll, the following charges, amongst others, having been brought forward:—

That being in attendance as a midwife at a confinement and having explained that the case was one in which the advice of registered medical practitioner was required, the midwife did not hand to the husband or the nearest relative or friend present the form of sending for medical help properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 20, and the advice of a registered medical practitioner having been sought, she neglected to notify the Local Supervising Authority thereof, as required by Rule E. 22(1)(a). The midwife neglecting to take and record the pulse and temperature of the patient at each visit, as required by Rule E. 14, and neglecting to enter true records of the patient's pulse and temperature in a note-book or on a chart carefully preserved, as required by Rule E. 14. A patient suffering from serious rupture of the perineum, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21(3). The midwife not being scrupulously clean in every way, including her person, clothing, appliances, and house, as required by Rule E. 2, and she did not on each occasion when attending her patient's wear a clean dress of washable material, as required by Rule E. 2, and was guilty of misconduct in recording pulses and temperature purporting to be those of patients whom she had attended, when in fact she had taken no such pulses and temperatures. Being in attendance at a confinement the midwife did not on each occasion disinfect her hands and forearms before touching the patient's generative organs or their neighbourhood, as required by Rule E. 4; she neglected to make use of the anti-septic precautions for washing the patient's external parts and swabbing them with an efficient anti-septic solution, as required by Rule E. 8(a). A child suffering on the third day from inflammation of and discharge from the eyes, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21(5). A midwife having been convicted on an indictment alleging that being a person over the age of 16 years having the custody of a child, she neglected the child in a manner likely to cause injury to its health, and had been sentenced to six months' imprisonment. A midwife having been convicted and sentenced to 12 months' hard labour for that she did unlawfully kill a woman.

**THE HEALTH OF MUNITION WORKERS.**—At the Royal Institute of Public Health on March 14th Mr. Edgar L. Collis, Medical Inspector of Factories, outlined the problems of modern industrial hygiene as presented to the Health of Munition Workers' Committee. The work of this committee has been based on the following principles: (1) Proper alternation of rest and work; (2) the supply of sufficient and nourishing food on which the efficiency of the worker largely depends; (3) the provision of proper lighting, temperature, fresh air, and protection against disease; (4) the fact that the physical organisation of woman, though weaker than that of man, is more suited to continued effort; (5) the necessity of providing human beings during immaturity with shorter periods of activity and longer periods of rest than are required by adults. After referring to the good work done by Welfare Supervision Committees (*vide THE LANCET*, Jan. 6th, p. 25), the lecturer concluded by stating

that many of these problems under consideration, whether concerning the employment of men, women, or children, have only recently been grappled with, and it was amazing that the present stage of industrial progress should have been reached without any serious attempt to solve them. Had the attempt been made earlier much of the bitter heritage of labour unrest which had descended to us might have been spared. He expressed the hope that, with the new insight which the war had brought us, a better understanding might prevail, and the welfare of the industrial population, upon which the prosperity of the Empire depended, be safeguarded to the utmost of our power.

A Royal Humane Society Certificate on vellum was presented to Dr. T. F. Ryan at Edmonton Military Hospital on March 10th for attempting the rescue of a lad who was drowned in a pond at Edmonton on Jan. 28th.

**BANFF INSURANCE COMMITTEE.**—At a meeting of the Banff Insurance Committee, held on March 10th, it was intimated that the Committee had decided not to allow the doctors to prescribe patent medicines, but only to allow prescriptions for medicines appearing in the P.B. and the B.P.C. lists. Doctors would be allowed to make "repeats" only on prescriptions which had been dispensed within the calendar month in which the prescription was dispensed.

**ROYAL DEVON AND EXETER HOSPITAL, EXETER.**—The annual meeting of the friends of this charity was recently held under the presidency of Sir E. Channing Wills. The medical report stated that the in-patients numbered 2185, an increase of 65 on the previous year, and a record for the hospital. The average daily number of occupied beds was 172. The financial statement was satisfactory and showed a total income of £15,207 compared with £12,360 in 1915.

**THE LATE DR. HENRY COLPOYS TWEEDY.**—Dr. Henry Colpoys Tweedy, who died last week at Clifton, Bristol, had passed his active professional life in Dublin. He graduated M.B. of Dublin in 1871, and was elected a Fellow of the Royal College of Physicians of Ireland in 1889. He was for many years visiting physician to Dr. Steevens' Hospital. Some 15 years ago his sight failed, and he was compelled to retire from practice, since when he has lived in the south of England.

**DONATIONS AND BEQUESTS.**—The late Dame Hester Mary Stewart has bequeathed by will £1000 each to the Zenana Bible and Medical Mission, the London Fever Hospital, Dr. Barnardo's Homes, the Royal Infirmary, Perth, and the Royal Infirmary, Edinburgh.—By will the late Mrs. Edith Harriet Scott left £1000 to St. George's Hospital. The residue of the estate, after providing legacies to other charities, is left in equal shares to Guy's Hospital, St. George's Hospital, and the Hospital for Diseases of the Heart, Soho-square.

The late Mr. Peter Reid has, among other bequests, left £20,000 to the Hospital for Sick Children, Great Ormond-street, for erecting and helping to maintain a convalescent home for the patients; and £500 each to the Hospital for Consumption and Diseases of the Chest, the London Hospital, the Metropolitan Convalescent Institution, St. Mary's Hospital, Paddington, St. Thomas's Hospital.—By will the late Captain Edward Vivian Dearman Bi-chall, D.S.O., has left £2000 to the chairman of the Buckinghamshire Territorial Association for the benefit of the wounded men of the 1st Bucks Battalion and for the widows and dependents of those killed in the war; and among other bequests £100 each to Gloucester Infirmary and Leeds Infirmary.—Miss Mary Grace Child has left by will £2000 to the London Hospital.—By will the late Mr. John Leigh has bequeathed £1000 to the Oldham Infirmary.

**ROYAL SUSSEX COUNTY HOSPITAL.**—The Royal Sussex County Hospital at Brighton has suffered financially from the war conditions and showed at the end of 1916 an adverse balance of over £2700. During the year 784 military cases were treated, a daily average of 60 beds being occupied by soldiers. The number of female in-patients exceeded by 73 those treated in 1913, which previously held the record of 1226 cases. The cost per bed rose last year to the unprecedented figure of £93 6s. 6d., while the financial support given by the public showed a considerable falling off. The deficiency in the year's working (£2703) has been met by a call upon the available fund, which is now practically exhausted. It had, by some at any rate, been anticipated, inasmuch as many suggestions had been thrown out for the establishment of pay-wards with a view of easing the burden of maintenance. But there are legal difficulties in the way, and at the annual court of governors the chairman of the board of management, in reviewing the financial position, pointed out that should the position necessitate the closing of the wards for a period they might possibly be opened as pay-wards. Lord Hythe, the new President, urged that the needs of the hospital should be brought home to the local branch of the League of Mercy with a view of securing aid from the King Edward's Hospital Fund.

## Parliamentary Intelligence.

### NOTES ON CURRENT TOPICS.

#### *Venereal Disease Bill.*

THE Venereal Disease Bill has been read a third time by the House of Lords. It is now under the consideration of the House of Commons.

#### *Criminal Law Amendment Bill.*

Further progress has been made in the Standing Committee of the House of Commons with the detailed consideration of the Criminal Law Amendment Bill. On Thursday, March 15th, the principal matter of discussion was the age of consent on the part of girls. An amendment was proposed to raise it from 16 to 17 years of age, and it received considerable support. Sir GEORGE CAVE, the Home Secretary, however, declined to accept the proposal, because on the experience of the past he feared that it would lead juries to acquit men who were charged with the offence on the ground that they had reasonable cause to believe that the girl was above the age. The amendment was rejected by 21 votes to 20. Clause 3 of the Bill, however, provides that reasonable cause to believe that the girl was of or above the age of 16 shall not in future be a defence to a charge under the principal Act.

On Tuesday, March 20th, the Committee was engaged in considering penal provisions in the Bill in regard to brothel-keepers and solicitation.

#### *Disabled Soldiers.*

The House of Commons on Monday, March 19th, rediscussed the provisions for disabled soldiers under the proposed Royal Warrant. Mr. BARNES, the Minister of Pensions, announced some minor changes in its terms.

### HOUSE OF COMMONS.

WEDNESDAY, MARCH 14TH.

#### *Prisoners of War in Turkey.*

Answering Mr. HUME-WILLIAMS, Mr. JAMES HOPE (representing the War Prisoners Department) said: The Turkish Government persist in their refusal to allow prisoners of war camps to be visited by representatives of the American Embassy. Seven of the camps were, however, visited in November by delegates of the International Red Cross Society—namely, those at Eski Shehir, Aifon Kara Hissar, Ismidt, Broussa, Konia, Kirshehir, and Yozgad, besides two hospitals at Constantinople and the Island of Prinkipo, where General Townshend is interned. The British prisoners at the camps visited numbered 182 European and 211 Indian officers and 658 European and 417 Indian non-commissioned officers and men. From the information obtained through the Red Cross delegates it appears that although the condition of the officers is on the whole not unsatisfactory, that of the rank and file leaves much to be desired and gives cause for much anxiety. There remained unvisited 14 camps and 3 hospitals containing, according to figures furnished by the Turkish authorities, 131 European officers and 1086 European and 8115 Indian non-commissioned officers and men. The information available respecting the camps unvisited is scanty and in general unsatisfactory, but has recently been somewhat more reassuring, at least as regards the transmission of the relief in money and kind which is continuously being issued by the United States Embassy, and for which H.M. Government are profoundly grateful.

#### *Medical Resources of India in the War.*

Mr. CHAMBERLAIN (Secretary for India) in the course of his remarks dealing with India's contribution to the war said: The House will not blame me if I spend a moment over the medical services. The medical arrangements of the Indian authorities, whether at home or abroad, have come under severe criticism, and this is not the occasion for me to offer any justification or any defence, but I want to tell the House in a few words what the Government of India did from the narrow resources, for after all they are very narrow resources, at their disposal. Forty field ambulances, 6 clearing hospitals, 35 stationary hospitals, 18 general hospitals, 9 X ray sections, 8 sanitary sections, 7 advanced depots, and 1 general medical store depot have been sent on service over-seas. The personnel provided for these units and other services amounts to 258 officers of the Royal Army Medical Corps, 704 officers of the Indian Medical Service, 40 lady nurses, 475 assistant surgeons, 854 sub-assistant surgeons, 720 British nursing orderlies, 2840 Indian ranks, and nearly 20,000 Indian followers. In order to meet the heavy demands on the Indian Medical Service nearly 350 officers have been withdrawn from civilian employment, and some 200 private practitioners and civil assistant surgeons have been given temporary commissions. In the subordinate

branches 205 assistant surgeons and 560 sub-assistant surgeons in various kinds of civil employment have been released for military duty. May I say at once, whilst abstaining from any plea in defence of either the Secretary of State for India or the Government of India, in connexion with the military arrangements, that, as far as I know, all the testimony from everyone who has had experience concurs in this, that the devotion and self-sacrifice of the officers of the Medical Services attached to the Expeditionary Forces have not been exceeded, and could not be exceeded, in this war. The House knows that this is not the last word of the Government of India on the subject.

THURSDAY, MARCH 15TH.

#### *State Registration of Nurses.*

Major CHAPPLE asked the Parliamentary Secretary to the Local Government Board whether, in view of the fact that all the great associations representing the nursing profession in the United Kingdom, including the British Medical Association, the Royal British Nurses' Association, the Matrons' Council of Great Britain and Ireland, the Society for the State Registration of Trained Nurses, the Fever Nurses' Association, the Association for Promoting the Registration of Nurses in Scotland, the Scottish Nurses' Association, the Irish Nurses' Association, the National Union of Trained Nurses, and the College of Nursing, Limited, have now announced officially their unqualified support of State registration, he would bring in a Bill to effect this purpose.—Mr. HAYES FISHER answered: I am aware that the bodies named have expressed opinions in favour of the State registration of nurses, but the information before me does not show that they are in agreement as to the character of the scheme. I cannot at present give any promise of legislation on the subject.

#### *A Case of Agoraphobia.*

Sir J. D. REES asked the Under Secretary for War whether agoraphobia was included among the diseases which disqualify persons otherwise qualified to serve in the Army; and, if so, how many agoraphobists had been granted exemption by medical boards since the war began.—Mr. MACPHERSON replied: In only one case, as far as is known, has this disease disqualified a man for service, and the man in question was otherwise of unsound mind, though not certifiable.

#### *Medical Examination of Recruits.*

Mr. GLANVILLE asked the Under Secretary for War whether he would consider the possibility of giving such a thorough medical examination to recruits as would prevent men passed for active service and similar categories taking up the time and attention of the military authorities for months until their shortcomings caused them to be relegated to C 3 category to which they should have been originally passed.—Mr. MACPHERSON wrote in reply: The whole question receives the constant and careful consideration of the War Office. The number of men, however, where the original classification has been revised is an infinitesimal proportion of the total, and considerably more men are raised in the category every month than lowered. My honourable friend appears to make a reflection upon the capacity of those members of the medical profession who are doing their work under great pressure, and I cannot let it pass without a strong protest. Considering the vast total of medical classifications carried out every day, the total number of mistakes made is surprisingly small.

TUESDAY, MARCH 20TH.

#### *Medical Men in Ireland and Military Service.*

Colonel MCCALMONT asked the Under Secretary for War whether it was in accordance with the decision of the Army Council that a civilian doctor in Ireland appointed in medical charge of troops in his locality before the war, who although of military age had been found medically unfit for general service by a board, was to be forthwith replaced by another local civilian doctor of over military age; if so, upon what grounds had it been decided to penalise young unfit doctors; and whether this decision would apply to doctors who had become unfit through military service.—Mr. MACPHERSON replied: It is in accordance with the wishes of the Central Medical War Committee that we should not employ young doctors at home, as this prevents others from volunteering. Young medical men who are unfit are employed on general service at home and not locally.

THE Raymond Horton Smith prize, awarded by the University of Cambridge to that candidate for the degree of M.D. who presents the best thesis for the degree during the academical year, provided that he has taken honours in a tripos examination, has been won by Mr. F. Roberts, B.C., M.D., designate of Clare. The subject of the thesis was "Degeneration of Muscle following Nerve Injury."

## Appointments.

*Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

- BARTROW, Dr. IRENE, has been appointed Assistant Medical Officer of Health (*pro tem.*) for Sheffield.  
 COOPER, H. G., M.B., B.C. Cantab., Certifying Surgeon under the Factory and Workshop Acts for the Altringham district of the county of Chester.  
 DICKSON, Dr. MARGARET SCOTT, Medical Officer of Dundee's New Maternity and Child Welfare Scheme.  
 HILLIARD, H., M.R.C.S., L.R.C.P., D.P.H., Anæsthetist to Charing Cross Hospital.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertiser is requested to communicate with the Editor.*

- BIRMINGHAM CITY EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary £300 per annum.  
 BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £250 per annum, with apartments, &c.  
 BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Female House Surgeon. Salary £200 per annum.  
 BLACKPOOL, VICTORIA HOSPITAL.—House Surgeon. Salary £250 per annum, with board, &c.  
 BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Female House Surgeon. Salary £150 per annum, with board, &c.  
 BRISTOL ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £210 per annum, with board, &c.  
 BURY INFIRMARY.—Junior House Surgeon. Salary £150 per annum, with board, &c.  
 DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant House Surgeon, unmarried. Salary £150 per annum, with board, &c.  
 EAST RIDING LUNATIC ASYLUM, Beverley.—Temporary Female Assistant Medical Officer. Salary at rate of £250 per annum, with board, &c.  
 EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.—Clinical Assistants in Out-patient Departments.  
 GLAMORGAN COUNTY ASYLUM, Bridgend.—Temporary Assistant Medical Officer. Salary 26s. per week, with board, &c.  
 GRIMSBY COUNTY BOROUGH.—Temporary Female Assistant Medical Officer. Salary £350 per annum.  
 GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £250 per annum, with board, &c.  
 IPSWICH, EAST SUFFOLK AND IPSWICH HOSPITAL.—Female Resident Officer.

- KENSINGTON AND FULHAM GENERAL HOSPITAL, Earl's Court, S.W.—Resident Medical Officer. Salary £150 per annum.

- LEEDS PUBLIC DISPENSARY.—Second Female Resident Medical Officer. Salary £200 per annum, with board, &c.

- LIVERPOOL, DAVID LEWIS NORTHERN HOSPITAL.—House Surgeon for six months. Salary at the rate of £150 per annum, with board, &c.

- LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Two House Surgeons for six months.

- MANCHESTER, BAGULEY SANATORIUM FOR TUBERCULOSIS.—First Assistant Medical Officer, unmarried. Salary £300 per annum, with board, &c.

- MANCHESTER CORPORATION.—Assistant Tuberculosis Officer. Salary £250 per annum.

- MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road.—House Surgeon. Salary £150 per annum, with board, &c.

- METROPOLITAN HOSPITAL, Kingsland-road, E.—Temporary Medical Officer for the Tuberculosis Dispensary.

- QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford.—House Surgeon.

- QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Physician and Casualty House Surgeon for six months. Salary £120 per annum, with board, &c. Also Temporary Anæsthetist.

- ROTHERHAM HOSPITAL.—Junior House Surgeon. Salary £150 per annum, with board, &c.

- ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Two House Physicians and Two House Surgeons. Salary £50 per annum, with board, &c. Also Junior Obstetric Assistant. Salary £62 per annum, with board, &c.; also care of 16 beds at Endsleigh Maternity Hospital. Salary given. Also Assistant Anæsthetist. Salary £93 per annum, with board, &c. Also to attend at Endsleigh-street Maternity Hospital. Salary £60 per annum.

- ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, S.E.—Temporary Honorary Assistant Physician.

- SHEFFIELD ROYAL INFIRMARY.—House Physician. Salary £120 per annum, with board, &c.

- SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician and Junior House Surgeon. Salaries £150 and £120 per annum respectively, with board, &c.

- ST. BARTHROLOMEW'S HOSPITAL.—Assistant Ophthalmic Surgeon.

- ST. PETER'S HOSPITAL, Henrietta-street, Covent Garden, W.C.—Junior Anæsthetist.

- TRURO, ROYAL CORNWALL INFIRMARY.—House Surgeon. Salary £150 per annum, with board, &c.

- THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Atherton (Warwick) and Minehead (Somerset).

## Births, Marriages, and Deaths.

### BIRTHS.

BOOTH.—On March 19th, at "Wyngarth," Breck Hill-road, Mapperley Plains, Notts, the wife of Captain N. Booth, M.B., B.S. Lond., R.A.M.C., of a daughter.

BUSHE.—On March 17th, at Tollesbury Knights Rectory, Witham, Essex, the wife of Staff Surgeon Charles Kendal Bushe, M.D., R.N., of a daughter, who survived her birth only a few hours.

GROGOON.—On March 20th, at 129, Camberwell-road, S.E., to the wife (*née* Florence Muriel Steele) of Jonathan Grogouo, M.R.C.S., L.R.C.P.—a daughter.

TAYLOR.—On March 12th, at the Vicarage, Walton-le-Dale, Lancs., the wife of Leonard H. Taylor, Lieutenant, R.A.M.C., of a son.

### MARRIAGES.

BAZETT—LIVESEY.—On March 10th, at St. Andrew's Church, Oxford, Henry Cuthbert Bazett, Captain, R.A.M.C., to Dorothy Livesey, daughter of the late T. J. Livesey and Mrs. Livesey, of Pueblo, Colorado.

CALTHROP—CHANCE.—On March 14th, at St. Barnabas' Church, Kensington, Edward Spencer Calthrop, R.N., M.B., B.S., to Eleanor Mary, only daughter of Mr. F. W. Chance, of Morton, Carlisle.

FRY—BECKER.—On March 14th, at St. Paul's Church, Tottenham, Captain Augustin P. Fry, R.A.M.C., to Elsie Blanche, eldest daughter of Mr. G. Becker and Mrs. Becker, Tottenham, N.

SMITH—USHER.—On March 12th, at Holy Cross Church, Lichfield, Vincent Smith, Lieutenant, R.A.M.C., to Hope, daughter of the late Major Usher, 7th Dragoon Guards, and Mrs. Usher, Rathdown Cottage, Greystones, Co. Wicklow.

### DEATHS.

BLOMFIELD.—On March 18th, at The Grove, Robertsbridge, Sussex, Dr. Samuel Bartlett Blomfield, aged 47.

GIBBINS.—On March 17th, at Holmdale, Parkstone, Kenneth Mayoh Gibbins, M.B. Lond.

HAMMOND.—On March 15th, died of wounds, John Maximilian Hammond, M.B., B.S., Lieut., R.A.M.C., aged 41.

HEARD.—On March 15th, at Bradford, the result of a stroke while serving as Lieut., R.A.M.C., Francis George Heard, L.R.C.P., L.R.C.S. Edin., aged 53.

MILLER.—On March 11th, killed in action, Archibald Ingram Miller, M.B., Ch.B. Edin., Lieut., R.A.M.C., aged 34.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

### CURIOSITIES OF WAR

THERE is no doubt that at the conclusion of the present war there will be many who have taken part in various ways who could furnish instances of the curiosities of war, which, if collected together, would make a large volume. In the year 1860, Thomas Carter, of the Adjutant-General's office, published a book of just over 400 pages, which was dedicated, with permission, to H.R.H. the Duke of Cambridge, and entitled, "Curiosities of War and Military Studies, Anecdotal, Descriptive, and Statistical." Some of the contents were new and some old. Of the old, we give the following example, which is of interest to the medical profession:—

*Singular Description of a Deserter from the Twenty-Second Regiment of Foot.*—(From the *London Gazette*, of July, 1689.)—It is away out of Captain Soane's company, in his Grace the Duke of Norfolk's regiment of infantry, quartered at Newport, in Shropshire, Roger Curtis, a barber-surg-on, a little man, with short black hair, a lit le curled; round visage, fresh-coloured, in a light-coloured cloth coat, with gold and silver buttons, and the loops stitched with gold and silver, red plush breeches, and white hat; he liv'd formerly at Downham Market, in Norfolk. Whoever will give notice to Francis Baker, the agent to this said regiment, in Hutton Garden, so that he may be secured, shall have two guineas reward.

The following paragraph in the book is also interesting, though its information is probably familiar to many of our readers:—

*Supposed origin of sashes.*—Sashes are believed to have been invented for the ease of wounded officers, by means of which (in case any of them were so badly wounded as to render them incapable of remaining at their posts) they might be carried off with the assistance of two men. They are now reduced to a very small size, and, of course, unfit for the original purpose.

Woman in Battle is the title of one section of the book. Here is related the life and adventures of Mrs. Christian Davies, the British Amazon, commonly called Mother Ross, who served as a foot soldier and dragoon in several campaigns under King William and the great Duke of Marlborough, and was eventually made a pensioner of Chelsea College by Queen Anne, dying on July 7th, 1739. The story is told also of Phoebe Hessel, born in Stepney in 1713, who served for many years as a private soldier in the 5th Regiment of Foot in different parts of Europe, and in the year 1745 fought under the command of the Duke of Cumberland at the battle of Fontenoy, where she received a bayonet wound in her arm. King George IV. allowed this aged veteran a pension of half a guinea a week, which she enjoyed for many years, dying at Brighton, where she long resided, on Dec. 12th, 1821, aged 108. There is a section of military epitaphs, and in it we find one to the memory of Thomas Thatcher, in the 2nd Regiment of the Hants Militia, who "died of a violent fever, contracted by drinking cold small Beer when Hot":—

Here sleeps in peace a British Grenadier,  
Who caught his death by drinking cold small Beer.  
Soldiers be wise from his untimely fall,  
And when you're hot drink strong or none at all.

### MAURITIUS MEDICAL REPORT.

It appears from the medical section of the Mauritius Blue-book for 1915 that the total population of the island on Dec. 31st of that year, exclusive of the dependencies (7320), was estimated at 375,420, showing a decrease of 813 on the population returns for 1914.

There were 11,893 births registered during the year. The law allows a delay of 45 days for free registration, and the number of births which were not registered owing to death intervening before registration was 1201. The total number of births was accordingly 13,094, of which 6747 were males and 6347 females, giving a proportion of 34·8 infants born to 1000 persons living. The deaths registered numbered 13,101, giving a proportion of 34·8 deaths to 1000 persons living.

The general health conditions during 1915 were not satisfactory. The number of patients treated at public hospitals showed an increase over that recorded in 1914. There was a considerable reduction in the number of patients attending dispensaries, but more out-door patients were treated in hospitals. The diseases that caused the largest number of deaths were malaria (4401), tuberculosis (959), pneumonia (710), and dysentery (636), but it should be observed that a medical certificate is not required in all cases. Only 33 cases of plague were registered during the year, as against 125 in 1914; it was the lowest total hitherto recorded in any year. There was a marked reduction in the number of admissions for enteric fever from 234 in 1914 to 188 in 1915. Malaria still causes more deaths than

any other disease. The number of deaths ascribed to fever was 4401, showing an increase of 487 on that recorded in 1914. The case mortality was 1·63 percent., as against 1·77 percent. in 1914. Malaria was most prevalent in March, April, and May, after the comparatively heavy rainfalls in February and March. The spleen census and the treatment of schoolchildren with quinine, as well as the free house-to-house distribution of quinine, have been continued. The number of children vaccinated during the year was 10,358.

The mean rainfall from 42 stations was 53·20 inches, as compared with an average of 75·84 inches. The highest temperature was 91·5° on Jan. 28th and the lowest 54·0° on August 22nd.

### ST. GEORGE AND THE DRAGON.

ON the new pound notes the figure of St. George and the dragon is worth studying and comparing with some of the early designs on our sovereigns and crown-pieces. The original design of this character was made by Benedetto Pistrucci (1784-1855), a gem engraver and medallist, and there is a legend that Pistrucci's original model was an Italian waiter who used to serve in a restaurant near Leicester-square, London, and that Pistrucci chose him for his fine figure. In 1817 a pattern crown-piece was made by Pistrucci with his design on the reverse but without the artist's name or initials, but on some afterwards he had his name in full, and then later B.P., which can still be seen on our sovereigns and crown-pieces, under the design. Pistrucci's figure portrayed a very muscular body, bent into a curve, the rider's face almost touching the crest of the horse's neck, with the muscular right arm only slightly bent and grasping a short dagger, for the spear is broken, and a part of the shaft is lying at the hind feet of the horse. Only the left hand holding the reins shows. The right leg is slightly bent, and the foot pushed forward. The figure on the pound note portrays an upright unmuscular body of inverted triangle shape, the right arm holding a spear is bent, and raised so high that the elbow makes an acute angle; and the whole of the left upper arm and hand holding the reins shows. The right leg is bent back, and the limb forms an acute angle. The horse's tail is drawn in instead of out, and the disposition of the forelegs is puzzling.

### DECENTRALISED PATRIOTIC EFFORT.

Mr. W. R. Boelter, late editor of the *Smallholder*, is the author of a penny pamphlet on "Parish War Societies: How to Form and Conduct Them" (published by the Smallholders' Union, Ltd., 7, Queen-street-place, London, E.C.), based upon an experiment in village organisation made by him in Wendy, Cambs. Mr. Boelter defines a parish war society as consisting of those members of a parish who know that the war is not to be won by fighting alone, but also by working, saving, and planning, and who have therefore banded themselves together in order to do these things more effectively than they could do them alone. In a parish war society Mr. Boelter finds the sort of flexible organisation which can be grafted upon any kind of war work already in being. The pamphlet describes the way of starting such a parish war society and the directions in which it has developed at Wendy. A welfare subcommittee has been one of these, charged with the duties of organising Red Cross work, of making comforts for the men in the fighting line and prisoners of war, and of arranging for the care of convalescent soldiers and other ex-Service men. This useful and stimulating pamphlet ends by suggesting rules for the running of such a society.

### THE RIGHT AND LEFT HANDS.

THE care of the limbs is now a subject of increased importance, and the comparisons between the right and left hand and right and left leg are of interest to many fighters, workers, injured persons, their relatives, the insurance companies, and the State generally. Ambidexterity is a matter to which more attention will probably be paid in the near future. Students of the subject maintain that as many stone "scrapers," "hammers," "pounders," and so forth, which were used without heads or handles, were made for use by the left hand as for the right, although the right hand came gradually to be preferred for offence and the left for defence, the right hand being termed the "throwing," "great," or "male" hand and the left hand the "female" hand. It is alleged that in Africa there are more ambidextrous men than in Europe. In the Arabian Nights' Entertainments, the Christian merchant who excused himself to his host for feeding with his left hand, explained that for the theft of a purse after spending all his money on a lady the judge had ordered his hand to be cut off and would have cut his foot off, too, but for the intercession of the owner of the purse. Lane's note is: "This law imposing the loss of the hand for a theft of

anything exceeding a quarter of a dinar in value, induced a Mussulman to inquire, "If the hand is worth 500 dinars (this being the fine for depriving a man of that member) why should it be cut off for a quarter of a dinar?" He was answered, "An honest hand is of great value, but not so is the hand that hath stolen." A dinar (Latin, denarius) was the name of a gold coin issued by the Caliphs of Damascus of about 65 grains troy.

Although the right hand does heavier and finer work than the left it is at the same time probably more alert in taking care of itself; but the right hand is not spared as much as it might be, and often the left hand might be given more work to do in lifting and carrying, thus saving the right hand from the after-effects of muscular strain which is frequently shown in a tremor of the muscles which may last for several hours, and even over the next day, making the complete control of the muscles of the right arm and hand impossible. This is more especially observed perhaps in those sedentary workers who take to hard and unaccustomed manual labour, such as digging and wheeling barrows and chopping wood. The muscles of the arm seem to have a much longer "memory" of any unwanted strain imposed upon them, even when the owner of the limb has forgotten the job which his arm has performed. This is evident when he tries next to handle a pen, for example, or to do some delicate and fine work with the hand.

#### THE HEREDITARY FACTOR IN PELLAGRA.

An elaborate study, by Charles B. Davenport, of the Carnegie Station for Experimental Evolution, and Dr. Elizabeth B. Muncey, of the Eugenics Record Office (Bulletin No. 16), leads to the conclusion that the data collected show no evidence of direct heredity. There may, however, be an hereditary predisposition to the disease in those families in which chronic gastro-intestinal symptoms have existed for several generations. The relatively high proportion of gastric and intestinal diseases among pellagrinous families seems to substantiate this hypothesis. Of the 105 families in which there is only one case of pellagra, only three gave a history of intestinal or skin diseases in the ancestors, and only one a history of antecedent insanity. The authors conclude that with this predisposition to the disease, direct contact or life in endemic areas might afford the exciting factor necessary for its development.

#### CEDAR OIL AS AN ADDITION TO AMBRINE.

To the Editor of THE LANCET.

SIR.—May I suggest as an addition to paraffin wax for an "ambrine" preparation the use of cedar oil? Though nominally a "volatile oil," it resinsifies rapidly in contact with the air, as every histologist knows, and of course possesses the antisepic properties of all its class. It would give toughness to the paraffin. I do not know what its present price may be; but as the product of the distillation of a waste product—chip shavings and sawdust of pencil cedar—(*Juniperus americana* and *J. bermudiana*)—it has always been among the cheapest of essential oils.

I am, Sir, yours faithfully,

MARCUS HARTOG, M.A., D.Sc., &c.  
University College, Cork, March 13th, 1917.

#### HERB-COLLECTING.

THE Gardening Association, which is under the patronage of Princess Louise, Duchess of Argyll, has issued a second edition of a useful booklet, "Herb-Collecting for Boys and Girls," by Mrs. T. Chamberlain and Miss E. C. Wheelwright. In it are given instructions as to the finding of plants, the seasons in which to gather them, and the preparation for sale, together with many other hints which will prevent the labour of children in collecting wild herbs for medicinal use proving useless, as it may do unless properly guided. Experience has shown that there is little or no call for many of the herbs recommended in the first edition of "Herb-Collecting," and in the new edition omissions have been made, while special attention is called to those plants for which there is a brisk demand. The booklets can be obtained from the National Herb Growing Association, Queen Anne's Chambers, S.W.1, or from the Gardening Association, Lower Sloane-street, S.W.1, price 3*d.* each, or 2*s.* 9*d.* per dozen, post-free.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

The following journals, magazines, &c. have been received:—Journal of the Royal Sanitary Institute, Public Health, Shield, Canadian Journal of Medicine and Surgery, Proceedings of the Royal Society of Medicine, Bulletins et Mémoires de la Société Médical des Hôpitaux, British Dental Journal, Clinique Ophtalmologique, Journal of Hygiene, Archives Médicales Belges, Review Neurology and Psychiatry, Maternity and Child Welfare, Canadian Medical Association Journal.

## Medical Diary for the ensuing Week.

### SOCIETIES.

#### ROYAL SOCIETY OF MEDICINE, 1, WIMPOLe-STREET, W.

##### MEETINGS OF SECTIONS.

Monday, March 23rd.

ODONTOLOGY (Hon. Secretaries—F. R. Smyth, F. N. Doubleday, J. Howard Mumfrey): at 6 P.M. (*Cases 5 P.M.*)

*Exhibition and Report* (followed by a Discussion):

On Clinical Cases of Gunshot Injuries of the Jaws.

Cases will be shown by Mr. G. Paton Pollitt, Mr. B. Maxwell Stephen and Mr. F. N. Doubleday from 5 to 6 P.M.

Tuesday, March 27th.

MEDICINE (Hon. Secretaries—Charles R. Box, W. Cecil Bosanquet): at 5.30 P.M. *Lunaria Demonstration:*

Dr. C. R. Box and Mr. Walter Edmunds: Autochromes illustrating the Rash of Specific Fevers.

HUNTERIAN SOCIETY, at the Skin Department of St. Bartholomew's Hospital.

Wednesday.—4 P.M., Dr. H. G. Adamson: Demonstration on Interesting Cases.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY AND THURSDAY.—5 P.M., Goulstonian Lectures:—Dr. C. H. Miller: Paratyphoid Infections. (*Lectures II. and III.*)

#### POST-GRADUATE COLLEGE, West London Hospital, Hammermith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simon: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Partoe: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simon: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Partoe: Operations.

#### THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

#### CHADWICK PUBLIC LECTURES.

THURSDAY (at the Royal Society of Medicine, 1, Wimpole-street, W.).—5.15 P.M., The Hygiene of the Soldier's Heart.

#### ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY.—P.M., Lecture XI.:—Lieut.-Col. Sir A. Pearce Gould, K.C.V.O.: Personal Habits in Relation to Public Health in Time of War. Prof. G. Sims Woodhead, Dr. G. B. Hunter, and Miss L. Barker have promised to take part in the discussion.

### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To the EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

## MANAGER'S NOTICES.

## ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8d. The rates of subscription remain as revised in October.

## TO SUBSCRIBERS.

**WILL** Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

## TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 7.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

## METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, March 21st, 1917.

The Lumleian Lectures  
ON  
MODERN ASPECTS OF HEART DISEASE.  
*Delivered before the Royal College of Physicians of London*

BY G. A. SUTHERLAND, M.D. EDIN.,  
F.R.C.P. LOND.,

MEDICAL ATTENDANT TO THE HAMPSHIRE AND NORTH-WEST LONDON HOSPITAL;  
PHYSICIAN TO THE PADDINGTON GREEN CHILDREN'S HOSPITAL.

LECTURE III.<sup>1</sup>

*Delivered on March 30th.*

MR. PRESIDENT AND GENTLEMEN.—Although new methods of treatment of heart disease have been introduced, it is questionable whether any addition of great value has been made to the armamentarium of our predecessors. The advantages of rest, of suitable diet, and of digitalis were well known to them. What has been done is to analyse and test more exactly the measures which are beneficial and to define with more precision the conditions and the cases for their suitable application.

"CARDIAC TONICS."

The term "cardiac tonic" is still in common use and is employed somewhat indefinitely. It is applied to drugs which are supposed to stimulate or increase the contractile power of the heart. Some cardiac tonics are supposed to act directly on the musculature and others through the nerves of the heart. If one takes a list of the so-called cardiac tonics and tries to ascertain the exact action of the individual drugs it will be difficult to state precisely what special result is to be looked for. Digitalis and its allies, strophanthus and squills, stand apart from all the others in this respect.

Balfour (1897) held that the fundamental action of the digitalis group was to increase the elasticity of the muscular fibre of the heart, so that it expanded more slowly and contracted more perfectly. Broadbent (1897) considered that digitalis caused a more complete expulsion of their contents by the energetic contraction of the ventricles, and also improved the suction action during diastole, thus withdrawing the blood which had been dammed back in the veins. Brunton found that digitalis acted on the cardiac muscle, on the intrinsic cardiac nerves, on the vagus centre in the medulla, and also on the arterioles. We do not find any clinical proof of the accuracy of these views. There was no precise knowledge of the underlying changes in cardiac failure which digitalis is specially fitted to remedy. Each authority seemed to draw his conclusions from few and imperfect observations, or even to make his observations for the purpose of supporting his previously formed conclusions. In many cases what would now be regarded as the outstanding changes in cardiac failure were relegated to an entirely subsidiary position.

It is interesting to note that 20 years ago the special symptoms which called for digitalis had been recognised. These may be summed up as cyanosis and dropsy, with a rapid, irregular pulse and breathlessness. This condition is most frequently due to auricular fibrillation, and is still the one in which the action of digitalis is most clearly demonstrated. Digitalis was used as a cardiac tonic, and having been found beneficial in this special type of case it came to be used indiscriminately in all forms of severe illness with cardiac weakness. When I was a house physician it would have been regarded as almost criminal to let a patient die without giving digitalis, whether the disease was pneumonia, typhoid fever, or pernicious anaemia. We believed that digitalis was the great cardiac tonic and always suitable if cardiac failure threatened. Other cardiac tonics and stimulants have had their day and are still used by those who believe they have seen good results follow from their use. Amongst them may be mentioned strychnine, caffeine, camphor, adrenalin, and pituitrin. The exact mode of their action on the heart, if any, has not been determined, and the type of case suitable for their application has not been clearly

differentiated. Digitalis, however, holds its own in the present as in the past.

EFFECTS OF DIGITALIS IN VARIOUS CONDITIONS.

Progress has been made, and although differences of opinion may still exist we are a good deal nearer the answers to the questions why to use digitalis, when to use it, and how to use it. The progress of scientific medicine is often delayed by the existence of unscientific beliefs, and the employment of digitalis in heart disease is an illustration. The one outstanding fact about the action of digitalis which has been fully established is that it slows the action of the heart under certain conditions. I propose to consider how this slowing is brought about; what effects follow from the slowing; and whether the ascertained beneficial effects from digitalis are not to be explained solely as the result of this cardiac slowing. In doing so no attempt will be made to dispute the various effects on the cardiac muscle obtained by physiologists and pharmacologists in their experimental work with large doses of digitalis. The pharmacologist cannot produce in animals those changes in the tissues and functions of the heart which are the result of disease, nor can he form any estimate as to what the results of digitalis in therapeutic doses will be in the treatment of cardiac disease.

In ordinary language slowing of the heart means slowing of the rate of contraction of the left ventricle, and this is estimated clinically by the pulse-rate or, if necessary, by auscultation of the heart. We have already seen that an increase in the ventricular rate or a serious disturbance of the cardiac rhythm is never primarily ventricular in origin. The ventricle follows but does not lead the cardiac rate or rhythm, which is always initiated in some part of the supra-ventricular tissues. In diseased conditions an increase of rate or a disturbance of rhythm is also started in the supra-ventricular tissues. Consequently it would appear that treatment should be directed to the supra-ventricular tissues from which the disturbance proceeds.

Here are two further points to be considered. First, it has not been shown that digitalis in medicinal doses—and we are dealing solely with digitalis as a therapeutic agent—has any direct effect on the wall of the left ventricle. Consequently we must not assume that digitalis acts on the ventricular muscle. Secondly, it has been shown that the slowing action of digitalis is through the vagus nerve, but it has not been shewn that the vagus has any direct action on the musculature of the left ventricle. These two points will be discussed more fully later. Meantime, assuming them to be true, we draw this conclusion—that digitalis slows the rate of the left ventricle without acting on the ventricle; and that it produces its effect through the vagus nerve, which also has no direct action on the left ventricle. It therefore follows that as the rate of the left ventricle is dependent on impulses proceeding from other parts (the supra-ventricular tissues), the action of digitalis through the vagus must be on these supra-ventricular tissues. In an attempt to slow the ventricular rate through the supra-ventricular tissues there are two possible lines of action: (1) to check the rate of impulse discharge at some over-active centre, or (2) to block some of the rapid contractile impulses at the conducting tissues so that a diminished number of them reach the ventricle. Clinically it can be shown that in slowing the heart rate this is the mode of action of digitalis, as in the following types of cases.

I. With Normal Rhythm and Rapid Regular Action.

CASE 1.—A girl of 11 years had suffered from several attacks of rheumatic fever with cardiac involvement. After six weeks at a convalescent home she was readmitted to hospital because of increasing dyspnoea and rapid cardiac action. For the previous three weeks the cardiac rate had averaged 120 to 130 beats per minute. She had not been able to be out of bed for a fortnight owing to breathlessness.

There was no pyrexia and no evidence of active rheumatic infection. The cardiac rate was rapid, averaging 124, and regular, and the rhythm was normal. Praecordial pulsation was strong and the apex beat was felt 1½ inches outside the nipple line, while the right side of the heart was felt pulsating to the right of the sternum. The murmurs present indicated mitral and aortic regurgitation. The liver was enlarged, extending 2 inches below the costal margin.

After a fortnight's rest in bed and salicylate treatment there was no improvement, and it was resolved to try the effect of digitalis in slowing the heart-rate. In 12 days the rate had fallen to 68, the amount of digitalis taken in that

<sup>1</sup> Lectures I. and II. were published in THE LANCET of March 17th (p. 401) and 24th (p. 437), 1917.  
No. 4883.

time having been 12 granules of digitalin (Nativelle), gr. 1/240 in each. Four days after the digitalis treatment was begun the heart was beating regularly at 80 per minute, and with a normal rhythm, as shown by the tracings. At the end of the course the apex beat was felt 1 inch outside the nipple line, and the right border of the heart did not extend beyond the right margin of the sternum. The liver edge was just palpable at the costal margin. The patient expressed herself as feeling very well, and was allowed out of bed, when she found she could walk about without any breathlessness. The action of the digitalis was successfully maintained after she left the hospital by small doses of digitalin. In this case the diminution in the size of the whole heart, coincidently with the slowing of the rate, was very striking.

This type of case is a common one in adolescent life. Rheumatic infection has led to carditis, in which myocardium, pericardium, and endocardium may be involved singly or in combination. Active signs of rheumatic infection (fever, &c.) are absent, but there is a persistently rapid cardiac action, the rate being from 120 to 140 at rest. In mild cases there are symptoms of cardiac weakness, as shown by the languor, disinclination for exertion, and shortness of breath when any exertion is made. In more severe cases symptoms of cardiac failure may be present and the breathing distressed, even when the patient is in bed. The rapid cardiac action seems to be an important factor in producing the cardiac weakness which leads to these symptoms. Digitalis grips the vagus nerve and stimulates its inhibitory action which tells on the first centre reached—namely, the sino-auricular node. The rate of impulse discharge here is diminished and a slower rate of the heart is established at the sinus, which leads to the slower ventricular rate. In cases of this kind, and they are not uncommon, we find no evidence of any direct action of digitalis on the contraction of the left ventricle or on the rate of the left ventricle. We trace the slower and stronger contractions of the ventricle directly to the slower cardiac rate established at the sino-auricular node.

#### II. With Auricular Rhythm and Rapid Regular Action.

CASE 2.—A boy of 10 had suffered for some years from occasional attacks of paroxysmal tachycardia. They had become more frequent and more persistent until at the end of an attack lasting for a month signs of cardiac failure set in. Apart from the cardiac condition, there was no evidence of disease in any part of the body, and he had never shown any sign of rheumatic infection.

The heart rate was 180 per minute and regular. There was diffuse precordial pulsation, not forcible, and considerable dilatation of the heart to right and left. Strong venous pulsation was to be seen and felt in the neck. A soft systolic murmur was audible over the precordia. The radial pulse was very small, feeble, and rapid, but apparently all the cardiac pulsations reached the wrist. The breathing was laboured and the ears were dusky. The liver was enlarged and free fluid was present in the peritoneum, while there was some oedema of the lower extremities and of the abdominal wall. Tracings showed an abnormal cardiac rhythm which was not of sinus origin but arose somewhere in the supra-ventricular tissues and most probably in the auricles.

After moderate doses of digitalis the cardiac rate fell to 96, the action was much stronger, and the dilatation was less marked. Diuresis set in, the dropsical symptoms rapidly disappeared, and the boy felt much relieved as regards his breathing. On stopping the digitalis, however, the rapid cardiac rate quickly returned, and this happened after each successive course of digitalis. An effort was therefore made to establish a firmer hold on the cardiac rate by means of digitalis. He was ordered 45 drops of the tincture of digitalis daily, and during 19 days he took 11 drachms in all, a dose being omitted occasionally when nausea or headache was present. This had the effect of producing marked instability of the cardiac rate, so that it changed from fast to slow with great frequency, on the slightest stimulus, and usually without any recognisable cause. The patient stated that he could always change the rate by breathing deeply. In the fast periods the rate was always the same, 170 to 180 per minute, and the abnormal auricular rhythm was present. In the slow periods the heart rate would at one time be 42 and at another a normal one of 80, while in both cases a normal rhythm would be present. A few days later the normal rate became established with very few and brief periods of tachycardia.

We had here a case of very rapid cardiac action, the impulse starting presumably in the auricular tissues, and the ventricle eventually showing signs of exhaustion from over-action. There was no evidence of rheumatic or other

infection, and the heart was sound until the onset of the tachycardia. Here again digitalis would appear to have gripped the site of impulse formation in the auricle, passing by the sino-auricular node which was thrown out of action by the new focus, but large doses of the drug and a large total amount were required before the inhibitory effect of the vagus was fully developed. The large doses were probably rendered necessary by the fact that the centre of disturbance was a particularly active one, as shown by the severity and the persistence of the tachycardia.

#### III. With Auricular Rhythm and Rapid Irregular Action.

In the form of auricular fibrillation this is a common condition, and the beneficial action of digitalis is now well known. How it acts would appear to be as follows: The sino-auricular node is out of action as auricular fibrillation is a state in which multiple stimuli originate all over the auricles and dominate the cardiac rhythm. Fibrillation itself is so firmly established that the vagus has no effect in checking it. The inhibitory action of the vagus may be regarded as passing over the heart until it reaches the auriculo-ventricular node and bundle, which convey the stimuli from the auricles to the ventricles, and producing there diminution of the conducting power (conductivity), the so-called partial heart-block. By this means many of the impulses passing towards the ventricle are checked *en route*, the rate of ventricular stimulation is lessened, and the rate of the ventricular contractions gradually falls.

It may be objected that there is no proof here that this is the action of digitalis in auricular fibrillation, but few who have studied the subject have failed to accept the explanation. The inference has this further in its favour. The fibrillary contractions continue unaffected in the auricles and the ventricular contractions continue of the same kind as before, so that only the junctional tissues remain. On them digitalis and the vagus are known to act. It may be said that the mere slowing of the ventricular rate in auricular fibrillation does not explain the good results from digitalis, and that the drug has a real "tonic" action on the heart muscle. A case like the following has a bearing on this question.

CASE 3.—A married woman of 30 years sought advice because of increasing shortness of breath on exertion, although she was still carrying on her usual house duties. She had had rheumatic fever in childhood. The heart showed the characteristic signs of mitral stenosis in the form of a well-marked presystolic thrill and murmur. There was no left-sided dilatation, but the right side of the heart was somewhat enlarged. The cardiac action was regular at 84 beats per minute. The pulse was small and regular. The condition was, in fact, such as it might have been found on examination at any time during the previous 10 years, except that the right side of the heart was slightly more enlarged. The treatment ordered was largely negative—namely, the avoidance of anything inducing cardiac effort, for it has been my experience that no benefit is derived from drug treatment at this stage of mitral stenosis.

The patient was not seen again for three months, when she gave the following history. Up to 10 days previously she had gone on with her housework as usual. That night, about an hour after falling asleep, she woke with urgent breathlessness, and could not lie down. She felt the heart beat rapidly and thumping at times. The distress of the dyspnoea had gradually diminished and she had finally been able to come to the hospital.

The dyspnoea was still present, but she could lie down. The pulse was extremely feeble and rapid, with occasional stronger beats, but was very difficult to count. The cardiac rate was 140 and the action was grossly irregular—the so-called delirium cordis. The heart was much dilated, the liver was enlarged, and there was slight cyanosis. At the apex a systolic murmur was audible, and there was no trace of a presystolic thrill or murmur. Two days later she was admitted to hospital, when the pulse was found to be 140 per minute and very irregular. On the following morning she woke feeling that all dyspnoea had gone. This was clearly due to the spontaneous cessation of the attack of auricular fibrillation. The pulse was 96 and regular. I saw her next day when she was lying in bed without any sign of cardiac distress. The pulse was 90 and regular. There was a well-marked presystolic thrill and murmur at the apex, indicating the return of definite auricular contractions. The liver was normal in size. In a few days she was out of bed and going about the ward.

Two months later the patient had another attack of cardiac failure with similar symptoms, and was readmitted. Tracings showed the characteristic adial and venous curves of auricular fibrillation. The cardiac rate was 140 and the

action very irregular. On full doses of digitalis the heart slowed down, and later on moderate doses the rate was kept under 90. Although the patient's symptoms had been entirely relieved by digitalis the fibrillation and cardiac irregularity persisted.

Here a first attack of fibrillation passed off, and with its cessation the signs of cardiac failure rapidly subsided. No one will suggest that the cessation of fibrillation was accompanied by any special increase of contractile power in the ventricle, except that the rapid rate may have produced a certain amount of exhaustion. But the ventricle was left in peace—that is to say, it was freed from the showers of stimuli which were reaching it from above, and by reason of the slower rate its contractions became stronger. In a second attack digitalis secured the same result—namely, a slowing of the ventricular rate, and when that was established the signs of cardiac failure again disappeared. The fibrillation persisted, but the exhausting effects of its rapid rate were held in check. The only difference between the results in the two attacks was that in the first instance the heart reverted to a normal rhythm and rate, while in the other an abnormal rhythm of the heart and an irregular action of the ventricle persisted. These are not factors of the first importance provided that the ventricular rate is normal or slow.

#### *IV. With Normal Rhythm and Slow Regular Action.*

We may refer to the action of digitalis when the cardiac rate is normal and a sinus rhythm is present, and symptoms of cardiac failure have developed. This condition is most frequently met with in degenerative forms of cardiac disease, and after middle life. If one pushes digitalis here the usual result is to produce partial heart-block or sinus irregularity; the ventricular rate may be a few beats slower, but the chief effect is to substitute an irregular ventricular action for a regular. Even if this is not injurious if not pushed to an extreme, it is not at all an advantage, for a regular rhythm with harmonious interaction of auricles and ventricles is always to be preferred. This type of case does not, as a rule, show any benefit from digitalis, save that if dropsy is present a diuretic effect may follow, possibly due to an irritant action on the kidneys.

#### *V. With Auricular Rhythm and Slow Irregular Action.*

Cases of auricular fibrillation are sometimes met with in which the ventricular rate is slow and irregular. They have always appeared to me to be of a mild type of cardiac failure—that is to say, the subjects do not present the severe symptoms of heart failure seen in fibrillating cases with rapid ventricular action. They may have a limited cardiac response to effort, traceable rather to cardiac degeneration than to the fibrillation. One may infer that in such cases the degeneration has attacked the auriculo-ventricular bundle, and has already produced a condition of partial heart-block, so that the conducting tissues will allow of the passage of only a limited number of the stimuli which are coming from the auricles. Consequently in such cases one would not expect any benefit from digitalis, whose special action has already been anticipated by the changes resulting from disease, and in my experience digitalis is of no use. In some of these cases when the patient exerts himself the ventricular rate is greatly accelerated and symptoms of distress are then evoked. Digitalis may do good in this condition by preventing the acceleration of rate through an increase of the block in the conducting tissues. If digitalis had any direct effect on the contractile tissues of the heart it ought to be manifested in this type of case when signs of serious heart failure develop, such as oedema, cyanosis, and breathlessness, while the cardiac rate is not increased. Here, also, my experience has been that no benefit has followed the use of digitalis.

#### *MODE OF ACTION OF DIGITALIS.*

We have now got thus far that digitalis would appear to act through the vagus on certain parts of the supra-ventricular tissues. We have seen that this action may be on the sino-auricular node, or on some abnormal focus of impulse production in the auricular tissues, or on the junctional tissues. It has been established and accepted that this action is shown more frequently and more effectively in the case of cardiac disease resulting from rheumatic inflammation—that is to say, the other great class of cardiac disease, that due to various forms of degeneration, does not respond so well. It is not known, and it has not been suggested, that the

vagus nerve is itself affected or in any way altered by rheumatic infection. The conclusion to which one is led is, therefore, that the cardiac tissues, those on which the vagus acts, are in themselves altered in some way so as to be rendered more sensitive to the action of the vagus. Rapidity of cardiac action means over-action in the stimulus-producing centre. Depression or moderation of over-action seems to be the great function of the vagus. One cannot depend on bringing into play this vagal action by means of digitalis in all cases of rapidly acting hearts, but there are some in which this action may be confidently expected, and they are especially those in which the heart has been affected by rheumatic inflammation. In connexion with vagal action there is also to be taken into account the fact that an over-acting centre tends to become exhausted and an over-stimulated conducting tissue tends to lose its conducting power. Thus the sino-auricular node may be so far prepared for an increase of vagal depression by its previous over-action, and the auriculo-ventricular bundle may be similarly prepared by over-stimulation from auricular impulses, as in the case of auricular fibrillation.

It would appear, further, that in the case of a rapidly acting heart which we desire to slow the problem is, will the vagus under digitalis stimulation be able to moderate the impulse-producing centre, or will the latter prove too powerful and maintain its rate? Under many conditions, as is well known, digitalis has no effect in slowing the heart, and here we may assume that the over-acting centre is too excitable. On the other hand, under other conditions the vagus can control the over-acting centre and check the disturbed action. When the vagus fails to check the rapid production of impulses to contraction at their centre, it has still a useful function left—namely, to prevent the disturbance reaching the ventricle through the induction of partial heart-block by diminishing the excitability of the conducting fibres. This protective method of heart-block is of extreme value in maintaining efficient ventricular action in many cases. One point about this action of digitalis may be referred to. It is an imitation of Nature's way of maintaining efficient cardiac (ventricular) contractions in similar conditions of distress. The natural means of preventing excessive ventricular rate and consequent ventricular exhaustion is by stopping a certain number of the impulses descending from above at the junctional tissues—a partial heart-block. This may or may not be sufficient. If it is not, by means of digitalis we can supplement the blocking action already existing and increase it to the extent necessary to relieve the ventricular distress.

If these views as to the action of digitalis are correct it would appear that the slowing effect on the left ventricle—from which we have traced all the benefit derived from digitalis—is accomplished without any action on the ventricular muscle. Further, it would appear that digitalis, the great cardiac "tonic," has no action whatever in medicinal doses on the cardiac tissues; it neither weakens them nor tones them up, but acts only on the vagus nerve by increasing its inhibitory functions. It does not seem necessary to assume any effect other than that of a slower rate, and the beneficial rest to the heart which follows.

#### *Effect of Compression of Vagus Nerve.*

By compression of the vagus nerve in man evidence is gained which supports the view that the action of digitalis is on the vagus and not on the heart muscle. Ritchie found that by digital compression of the vagus he could slow the whole heart, the normal rhythm being maintained, and the action being on the sino-auricular node. He could obtain no evidence of a direct action on the other tissues in the auricle, and in no instance has he observed auricular fibrillation to be checked or arrested by vagus compression. He failed to find any direct effect on the ventricles by vagal stimulation. Ritchie states that although in animals the conduction of stimuli to the ventricles through the junctional tissues may be impaired by vagal stimulation, in healthy human hearts he failed to obtain any depression of the conductivity of the auriculo-ventricular bundle unless there was some antecedent impairment of its function. In many cases of auricular flutter compression of one or other vagus was found to induce well-marked blocking of stimuli to the ventricles. Whenever the ventricular rate was slowed, the slowing was always the result of the action of the vagus on the supra-ventricular tissues. In cases of

complete heart-block the rate, rhythm, and strength of the ventricular beats were found to be uninfluenced by vagal stimulation.

We have already considered the clinical effects of digitalis on cardiac action. Now if we compare the results of vagal stimulation by digital compression there is a striking similarity in the effects produced. In both cases the results are primarily inhibitory and not augmentory of cardiac functions. In both cases there may be a local action on the sino-auricular node, the auriculo-ventricular node, or the auriculo-ventricular bundle, but never directly on the ventricles themselves. In the one case mechanical stimulation produces effects which are temporary and cannot be long sustained; in the other, digitalis produces identical effects which can be regulated and indefinitely prolonged. Still some would ask us to believe that as the vagus picks out certain areas and certain functions of the heart in the exercise of its physiological rôle, so digitalis picks out the same areas and the same functions in the exercise of its therapeutic rôle.

#### OBSERVATIONS ON DIRECT ACTION OF DIGITALIS.

We have seen the typical class of case in which digitalis is useful—namely, the rheumatic heart with a rapid rate or with a rapid and irregular rate, and signs of left ventricular failure. This class will comprise some 90 per cent. of the cases in which we can state before treatment that digitalis will do good, and the way in which it will do good, and the good which it will do. Regarding how many drugs can the same statement be made? We are not tied down to this class of case, because in a sense the investigation into the action of digitalis is only in its infancy—certainly it is very far from being completed. But we have reached this conclusion that it is foolish to give digitalis solely because of cardio-weakness or of cardiac dilatation or of valvular disease, irrespective of the special conditions present. It is equally foolish to refrain from giving digitalis because of some supposed action on the contractility or relaxation of the left ventricle, or because of the presence of some lesion supposed to militate against the use of digitalis such as aortic incompetence or mitral obstruction.

Physiologists somewhat vaguely, and pharmacologists more precisely, have dealt with the action of the vagus and of digitalis on the contractile power of the left ventricle. In this connexion one law must be kept in mind—namely, that the cardiac muscle, when it contracts, contracts with all the power which it possesses at the time. Gaskell puts digitalis into the class of substances which act in the direction of bringing about a tonic contraction of the left ventricle, as opposed to the unscarin class which brings about an atonic condition of that muscle.

Cushny has concluded from his experiments with large doses that digitalis strengthens the contractions and often lessens the relaxation of the heart by direct action on the cardiac muscle. Anything that Cushny writes about digitalis must be received with respect, but when he enters the clinical field we are at least entitled to offer criticism. The clinical problem he set himself to decide was whether the therapeutic effects of digitalis are to be attributed to stimulation of the inhibitory action of the vagus or to its direct action on the cardiac muscle. The method he employed was to paralyse the vagus by means of atropine before and after the use of digitalis. If a heart slowed by means of digitalis did not show an increase of rate under atropine he concluded that the slowing was due to a direct action of digitalis on the heart muscle, the vagus having been thrown out of action by the atropine. From a considerable number of clinical tests he drew the following conclusions:—

(1) The members of the digitalis group slow the pulse in a certain number of cases in which the rhythm is given by the normal pacemaker, and as a general rule this slowing may be removed by atropine, and is therefore inhibitory. In other cases, however, the sinus slowing and block are unchanged by atropine, and then arise from the direct action of digitalis on the conducting fibres from the pacemaker to the auricle, and from the auricle to the ventricle.

(2) In auricular fibrillation digitalis slows the heart from some direct action on the heart and not from stimulation of the inhibitory mechanism, for atropine does not restore the original rate of the released heart. The reduction in rate may be due to a direct depression of the conduction or of the excitability of the heart muscle by digitalis. But it is suggested that these functions are reduced indirectly through the improved nutrition of the heart from the augmented power of contraction of the heart muscle.

(3) The inhibitory stimulation induced by digitalis, therefore, does not play any part in the beneficial action of the drug, which is to be ascribed to its direct action on the cardiac muscle solely.

It is surprising to learn that in cases of auricular fibrillation, where the slowing of the ventricular rate under digitalis is so striking, the vagus does not come into play at all and an entirely different process is at work. I question whether this conclusion is justified by the clinical tests employed. The atropine test was employed when the vagus was fully digitised—that is to say, when the vagus centre was being strongly and continuously stimulated. To paralyse the vagus, therefore, one required not an ordinary physiological dose of atropine, but a dose proportional to the degree of vagus stimulation by the digitalis. One may put a normal individual to sleep with 20 grains of bromide of potassium, but such a dose will do little to quiet an alcoholic subject suffering from delirium tremens. In order to make his test conclusive Cushny ought to have greatly increased his dose of atropine. Not that I advise this continuation of his tests, because in all probability the patient would die from atropine poisoning before the vagus escaped from the grip of digitalis. The results which Cushny obtained are exactly those which one would expect in auricular fibrillation with the vagus fully digitalised, if one believed that the slowing of the heart was through the vagal action. Mackenzie, dealing with the same type of case as Cushny, differs as to the clinical facts and the conclusions to be drawn from them. He says:—

So far as our observations go the action of atropine in increasing the rate when it has slowed, seems to indicate that digitalis acts through the vagus nerve, both in the slowing which occurs in auricular fibrillation, and in partial heart-block.

But the clinical conclusions of these two authorities may be satisfactorily reconciled if we assume that the larger the amount of digitalis taken the bigger will the dose of atropine require to be in order to throw the vagus out of action. Mackenzie was dealing with small doses of digitalis and Cushny with large ones.

#### *Consideration of Cushny's Conclusions from Clinical Side.*

On the clinical side also one must take exception to the basiness of Cushny's conclusions as to the direct action of digitalis on the heart, after he considered that he had eliminated the vagal factor. "The reduction in rate may be due to a direct depression of the conduction or of the excitability of the heart muscle by digitalis." It certainly would be curious if digitalis imitated exactly the well-known functions of the vagus described in this sentence. "But it is suggested that these functions are reduced indirectly through the improved nutrition of the heart from the augmented power of contraction of the heart muscle." That is to say, that with a cardiac (ventricular) rate say of 150 the heart is so toned up by digitalis that the rate is slowed. But we find clinically that we cannot strengthen the cardiac contractions until the rate has been slowed down. We get no evidence of stronger contractions, and the patient gets no relief from the symptoms, and the physical signs of cardiac failure do not alter until after slowing has taken place.

Is it not a commonplace of medicine that with a rapid cardiac action we cannot have a strong pulse? Take the case of a healthy young man with a rapid pulse under some form of excitement, and we find it small and weak. When the excitement has passed off and the heart rate has slowed, we find the pulse stronger and fuller. Does any clinician doubt that the cardiac action was weaker when the rate was rapid and that it was stronger when the rate had slowed and because the rate had slowed? Has experience not shown that the faster the cardiac rate the weaker are the contractions? Can we imagine digitalis producing in a rapidly acting heart the same powerful contractions which we know will follow from the mere slowing of the rate? This suggestion of Cushny's would appear to be merely a revival of the old pharmacological view, which was accepted therapeutically, that there must be some direct action of digitalis on the cardiac muscle. The acceptance of this view, without any proof as to its accuracy when the drug was used in medicinal doses, led to the great misuse of digitalis in the past.

Accepting the "all-or-nothing" action of the ventricle in contracting, we must take the other fact that if the ventricular rate is increased the contractions are weakened because the resting-time is diminished. Rest and relaxation

of the muscle are essential if the ventricle is to evolve its full power of contraction. Contraction, relaxation, and rest are the three elements in the normal ventricular action. Physiologists have taught that the tonicity of the ventricle is increased by digitalis and that the contractile power is increased, using large doses for the experimental proofs. If the tonic contraction of the ventricle is increased it follows that the relaxation is diminished *pari passu*, for a tonic contraction in the physiological sense means a prolonged contraction without relaxation. If the relaxation is diminished the complete filling of the ventricle cannot be effected. If the ventricle is not filled the efficiency of a ventricular contraction in carrying on the circulation must necessarily be impaired.

It is difficult to see how these results of poisonous doses of digitalis in physiological experiments can be made use of in cardiac therapeutics. The well-known experiment of bringing a frog's heart to a standstill in tonic contraction of the left ventricle has no bearing on our therapeutic dosage, for anything of this nature would be singularly inappropriate in an attempt to help a struggling ventricle. If physiologists say that the contraction of the ventricle is increased by digitalis through the vagus there is this further difficulty. The physiological action of the vagus is inhibitory; its recognised effect under digitalis is to inhibit cardiac functions—for example, inhibition of rate, inhibition of conductivity, inhibition of excitability, &c. So that if it should under the same conditions increase the contractility of the ventricles, there would be a change in the normal function of the vagus which can only be described as puzzling. Gaskell, however, definitely states that the "staircase phenomenon" which arises after an experimental standstill of the whole heart through vagal stimulation is due to exhaustion of contractility. He points out that the vagus stimulation depresses all the functions and their restoration is gradual, the restoration of contractility being shown by a gradual increase in the strength of the beat—the staircase phenomenon.

#### *Conclusions as to Different Actions of Digitalis.*

Cushny's conclusions as to the action of digitalis in cases with a normal rhythm of the heart are also difficult to follow, and for this reason. He finds that in some cases this action is inhibitory and through the vagus, while in others there is a direct action of digitalis on the conducting fibres from the sino-auricular node to the end of the auriculo-ventricular bundle. So that in the same class of case we have two entirely different actions of digitalis, the one on the nerve and the other on the muscle. This is a difficult doctrine to accept, but it does not complete the exposition of the action of digitalis. In the fibrillating cases, that is, those with an abnormal rhythm, these explanations are dropped, and he suggests a third—namely, "an augmented power of contraction of the heart muscle." From these statements one gathers that in Cushny's clinical experience digitalis may stimulate the vagus directly, or may depress the conductivity of the heart directly, or may increase the contractility of the heart directly. The path of clinical medicine is not made smooth by such varied and uncertain action on the part of digitalis. Surely if we can explain our therapeutic results by one line of action, clearly aimed at and clearly manifested in clinical work, we shall prefer it. The line of action is that digitalis acts on the supra-ventricular tissues through the vagus nerve, and by checking impulse production or impulse conduction slows the rate of the ventricles.

It would appear that nature has not supplied any natural paths by which the ventricles can be stimulated directly to increased contraction. In the field of experimental medicine Ritchie and others have failed to produce a direct effect on the ventricular contraction by stimulating the vagus. The effects of stimulation of the accelerator nerves of the heart by experiment or by drugs have not shown any definite action on the ventricles. Is it not possible that the natural powers are the best defenders of ventricular action and that our efforts to aid it by direct stimulation are wasted? If we consider the condition of a patient suffering from paroxysmal tachycardia, the heart having been previously healthy, we may find marked signs and symptoms of cardiac failure. On the occurrence of spontaneous cessation of an attack there is a rapid disappearance of all the signs of cardiac distress. Is it any use giving drugs to increase the cardiac (ventricular) contractions? The heart

has been beating at a rate of about 200 per minute. It is impossible for the contractions to be powerful at that rate; the only question is, Will they be sufficient to carry on the circulation? When the pulse-rate drops to 80 the whole scene changes, and by the mere slowing of the rate the cardiac (ventricular) contractions at once becomes stronger and an efficient circulation is established. If given a sufficiency of rest and relaxation the ventricle is quite capable of doing all that is required in the way of contraction. A similar state of affairs is seen in cases of auricular fibrillation, as already referred to, when the cessation of an attack is quickly followed by the return of the heart to the *status quo ante*. The ventricle needs no stimulation to bring out its contractile power when rest and relaxation are afforded. So when digitalis is used in the case of auricular fibrillation and the same relief of symptoms follows the slowing of the ventricular rate, it seems superfluous to bring in as a pharmacological explanation an assumed action of digitalis on the contractile powers of the ventricles.

#### *Clinical Experience in Support of Digitalis Acting Beneficially by Slowing of the Heart.*

If digitalis has any therapeutic action on the wall of the left ventricle it ought to be capable of clinical demonstration. The typical case for this purpose is not uncommon—namely, one in which there is a failure of the left ventricle with a normal rate and rhythm of the heart, and with definite signs present, for example, oedema, oliguria, and breathlessness. A record of a series of cases of this type, with details as to the benefits which followed from the use of digitalis, would go far to settle the question as to the direct action of digitalis on the ventricles. But I do not find such cases to be common amongst published records and I cannot supply any from my own experience.

Recently the electrocardiograph has been employed to test the effect of digitalis on the cardiac records and certain changes have been discovered in the ventricular peaks, notably in the T wave. Further, under full doses of digitalis a ventricular extra-systole sometimes occurs. It is scarcely convincing to assume from these facts that digitalis acts directly on the ventricular wall. As bearing on the subject of the action of digitalis on the wall of the ventricle there is this fact to be remembered. When the cardiac rate has been much reduced by digitalis, say to 40 ventricular beats per minute, as the result of full doses, we sometimes find that the ventricle "escapes." Ventricular escape means that the ventricle starts its own independent rhythm and contracts when the pauses between the normal beats are very prolonged. This shows that the ventricle itself has been so little affected by digitalis as compared to other parts of the heart that its idio-rhythm emerges unaffected and unimpaired whenever an opportunity presents itself. We have little evidence of the other functions of the ventricle being affected directly by digitalis, and we can state definitely that the idio-ventricular rhythm is not affected at all.

The other great cardiac tonic is rest. Why does rest relieve the weakened or failing heart? There is no question here of a direct tonic action on the cardiac muscle, such as has been claimed for digitalis. There is no positive action of any kind on the cardiac muscle. But there is a negative one in the diminution or cessation of the rapid cardiac action which follows from physical exertion and mental excitement. In other words, rest leads to a slowing of the cardiac rate, and from this slowing follow those benefits which have already been described as the result of digitalis therapy. So far as we are entitled to dogmatise from clinical experience, we may say that all the ascertained benefits derived from digitalis and from rest in rapidly acting and failing hearts are to be traced to one and the same result—namely, the slowing of the heart-rate. This slowing may be brought about in different ways and by various means, but it is the best cardiac tonic we possess.

#### *NEED OF FURTHER INVESTIGATION.*

While digitalis gives its most striking results in cases of very rapid and grossly irregular cardiac action, further investigation is required as to its value in less severe cases and before signs of definite cardiac failure have manifested themselves. There is a large class of sufferers from cardiac insufficiency—that is to say, the reserve power of the heart has gone and the response to anything save mild exertion is very limited. Take the case of mitral stenosis where the above conditions are present, but where the pulse-rate is still

normal or slow. I do not anticipate any benefit from digitalis in such a case.

In others, however, we find the pulse-rate persistently rapid and much increased on exertion. It is extremely probable that this increase of rate has a definite result in the way of producing over-action and weakening of the left ventricle, as well as of the right. In several cases of this nature I have given digitalis in order to prevent weakening of the heart and to postpone, as far as possible, the onset of cardiac failure. It has seemed to me that distinct benefit has followed in these cases from the slowing of the heart induced by digitalis. The action was always on the sino-auricular node, so that the normal rhythm was preserved, and the patients had always had rheumatic infection, so that the heart may have been in a sense prepared for digitalis. As a preventive of cardiac failure, the usefulness of digitalis in slowing the heart under these special conditions might be further tested.

#### CONCLUSION.

I have now dealt, very imperfectly as I know, with some additions to our knowledge of heart disease, and some changes in our views regarding it. As an observer I cannot reproduce to you the results exactly as they are but only as they appear to me to be. Looking backwards we recall with gratitude the light thrown on the subject of heart disease by eminent clinicians in the past. Advance in clinical medicine and by clinical methods has not come to a stand-still. Looking forwards we see one of the best guarantees of future progress in the existence of a band of British workers who are devoting themselves enthusiastically to the further elucidation of the problems of heart disease. May I add that this College desires to extend to them all the support and encouragement in its power.

## FURTHER EXPERIENCES WITH EMETINE BISMUTH IODIDE IN AMOEBOIC DYSENTERY, AMOEBOIC HEPATITIS, AND GENERAL AMOEBIASIS.

BY GEORGE C. LOW, M.A. ST. AND., M.D. EDIN.,  
ASSISTANT PHYSICIAN AND LECTURER, LONDON SCHOOL OF TROPICAL  
MEDICINE.

(Report to the Medical Research Committee.)

IN THE LANCET of August 19th, 1916, Dobell and myself briefly described three cases of infection by *Entamoeba histolytica* treated by emetine bismuth iodide. Two of these have since been followed up accurately, one W. (No. 3) by Dobell, the other C. (No. 2) by myself. Neither of these has ever shown *E. histolytica* cysts again and C. has had no further clinical signs of dysentery. Dietetic errors and cold and damp have, it is true, produced a certain amount of abdominal discomfort and slight pain, but, after extensive ulceration of the bowel, one could not expect otherwise. With these symptoms no blood or mucus appeared in the stools and, as stated above, no parasites were found. Coincident with the disappearance of the dysenteric symptoms the patient improved in general condition and gained weight. Both these cases, I think, may be considered as complete and permanent cures. Tables I. and II. show at a glance the detailed examinations of the stools.

The value of the double iodide of emetine and bismuth, by the mouth, in the treatment of histolytic carriers is now fully recognised; it remained to be seen, however, whether the drug would be equally efficacious in cases where liver involvement had also taken place. In the following series of cases to be described three cases of amoebic hepatitis figure and, as will be seen later, very good results have also been obtained. In addition an example of the somewhat rare condition "general amoebiasis" is included. By this term is meant a febrile state without dysenteric and manifest liver symptoms, yet responding quickly to treatment by emetine. *E. histolytica* cysts may be found only with great difficulty, but if sufficient numbers of faecal examinations are made they should eventually be demonstrable.

*Method of administration.*—To begin with, keratin-coated tabloids and steartettes were tried and appeared to act satisfactorily. In one instance, however, suspecting that the drug was not being absorbed, the stools were carefully examined and three steartettes were recovered quite unchanged. The uncertainty of such an occurrence taking place in other cases decided one therefore to employ the drug in all the other patients as the loose powder in an ordinary gelatin capsule, similarly to the first cases treated by Dobell and myself. The dosage in all the series has been 3 grains nightly for 12 consecutive nights, as originally recommended by Dale.

A certain amount of sickness occurred in some of these, but this was never of sufficient importance to interfere with the continuation of the treatment, and the same may be said of the diarrhoea which is sometimes met with. To prevent sickness the precautions that were of use in the ipecacuanha days may be employed, the drug, however, in this instance being given on a full and not on an empty stomach. During the course the patient is better kept strictly in bed, the diet being arranged in accordance with the acuteness or chronicity of the symptoms. For most cases a light diet consisting of milk, white meat, and white fish will be found most suitable. At 10 P.M. a small meal should be given, arrowroot, sago, tapioca, or cornflour with a little milk, for example and then immediately after this the capsule is taken. Five to ten minutes later some boiling water should be sipped, and this should be repeated if any sign of nausea or sickness occur throughout the night. For the first few nights, until one sees how the patient is to tolerate the drug, the pillows should be removed so as to keep the head low, no movement should be allowed, and if saliva accumulates in the mouth it must on no account be swallowed, but should be expectorated or removed by cotton swabs. If after all these precautions the patient is still sick a mustard leaf may be applied to the epigastrum on subsequent evenings, or 10 to 20 minims of tinct. opii may be given half an hour before the administration of the emetine. Such precautions will greatly mitigate, if not entirely prevent, sickness.

The occurrence of this symptom is a very variable one; sometimes the first doses produce it and then a tolerance is established, while in other cases it appears towards the end of the course or irregularly throughout it. Three to four hours after taking the capsule is the usual time for the sickness to appear; there may be one emesis and then no more,

or this may be followed up by others with some nausea and discomfort on the following day. In private practice and in ordinary civil hospital practice, when the drug is given in a proper manner and with the ordinary precautions the symptom is of little importance, and may be entirely disregarded in the majority of the cases. In the old days such patients used to take their ipecacuanha without any trouble, the symptoms produced being much more unpleasant than those met with in the above drug.

As regards diarrhoea, a certain amount of this is beneficial rather than otherwise; if excessive it may easily be checked by the administration of opium.<sup>1</sup>

#### Notes of Cases.

**General amoebiasis.—History.**—Patient (McC.) went to Africa April, 1916. He soon had some slight attacks of malaria, but otherwise kept well. In October of the same year he began to feel run down and got tired very easily. He then went and consulted Dr. Gray at Lagos, who, on examining his stools, found *E. histolytica* cysts present. Seven injections of emetine, gr. 1, were given and the patient returned to work. General weakness and the tired feeling soon appeared again, so it was decided to send the patient home.

**Examination.**—Temperature varying from 101–102° F. at nights. Looks seedy and has lost weight. Teeth black, but sound. Small glands palpable in posterior triangles of neck. Lungs nil. Heart sounds a little weak; pulse 100, feeble. Liver, perhaps a little enlarged upwards, level of 5th and 6th ribs and costal margin. Spleen not palpable. No pain on shaking liver nor on deep pressure and percussion. No pain or tenderness over colon. Blood examination: R., 4,600,000; W., 13,000; Hb, 90 per cent. Differential count per cent. was: Polymorphs, 70%; large mononuclears, 10; lymphocytes, 17.5; eosinophiles, 0.5; transitional, 1; mast cells, 0.5. Number counted, 200. No malarial parasites or trypanosomes. Urine: No albumin, blood, or sugar. Faeces: Heavy infection with *Entamoeba coli* cysts, one amoeba? species. Two doubtful cysts that might have been histolytica. Wassermann reaction negative on two occasions.

As regards a past dysenteric history, the patient stated that he had never had clinical signs of dysentery nor, as a matter of fact, even any diarrhoea. He was very emphatic about this. Further, he never had had any liver pain or tenderness, his only clinical signs being weakness, some loss of weight, and irregular temperature.

**Treatment.**—As his temperature was high and I did not like his appearance, and as Dr. Gray had found definite histolytica cysts in his faeces in Africa, I did not wait, but started a course of emetine bismuth iodide at once. This was begun on the night of Jan. 11th, 1917, and its effect upon the temperature was at once apparent, this quickly dropping to normal. As marked as this was the effect of the drug on the patient's general condition, he stating that he felt very much better and, further, his leucocytes, which were raised when he came into hospital, also became normal.

**Further history.**—The improvement has continued up to the date of writing this paper, the patient has had no further fever, he has steadily gained in weight, histolytica cysts have not reappeared in the faeces, and to all intents and purposes he is cured.

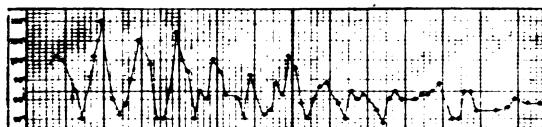

Chart showing the temperature of patient (McC.).

Table III. shows his faecal and blood examinations and the chart his temperature. A study of the former shows that the coli cysts, though disappearing at first, returned and became as numerous as before, a point specially noted by Dobell in several of his series of examinations.

#### Amoebic Hepatitis Cases.

**1.—History.**—Patient born in England, went abroad to India in 1900. Served there since with usual leave home. Came home to England April, 1916. Previous illnesses: Attack of dysentery three years ago, very bad one. Since that date had had relapses off and on. Last attack a month ago. A little blood and mucus. Twelve stools a day one day during this period. Treated in India. ? ipecacuanha, never emetine. Frontier sores two years ago, malaria several attacks, never venereal. Present condition: Lately has been very weak, and this has gradually been getting worse. Has lost weight, about a stone; sweats at nights.

<sup>1</sup> Dr. H. H. Dale, who has read this paper in manuscript, tells me that recent experience seems to indicate that the trouble of nausea and vomiting may be eliminated, or reduced to trivial proportions, by giving the double iodide in pills coated with sa'ol. Of a number of formulae which have been tried the most successful was a pill with simple syrup as excipient and sa'ol coating. Such pills usually pass through the stomach without causing trouble, and appear to break up satisfactorily in the intestine, so that the curative effects are good.

**Examination.**—Looks ill. Teeth very bad. Stripped, very thin. Apices shrunken, poor chest, somewhat pigeon-shaped. No definite signs of tubercle; no dulness at right base. Heart sounds faint; no murmurs. Liver level of 6th and 7th ribs and a little below costal margin; slightly tender at one place and uncomfortable on shaking. Spleen level of 9th–11th ribs. Urine: No albumin, blood, or sugar. Faeces: No amoebae or cysts first examination. A further examination three days later showed scanty histolytica cysts. Blood examination: R., 4,900,000; W., 14,000; Hb, 95 per cent. Differential count: Polymorphs, 74; large mononuclears, 4; lymphocytes, 20; eosinophiles, 1; transitional, 1 = 100.

**Diagnosis.**—Amoebic hepatitis. ? abscess commencing.

**Treatment.**—Usual course of emetine bismuth iodide, 3 gr. nightly for 12 consecutive nights. Steartettes were used to begin with, but later were crushed up into powder, as about this same time I had another case in which these were passing unchanged. The patient quickly lost his liver pain. He expressed himself as feeling very much better, his leucocytes fell to normal, and he began to pick up weight. No cysts have been found in his stools since taking his course. Though still a little nervous and excitable, symptoms not associated with dysentery specially, he is now well and has had no further signs of liver pain. Table IV. shows the results of his treatment at a glance.

**2.—History.**—Patient had lived in India for 12 years. Previous illnesses: Enteric in 1906. Slight attacks of colitis on several occasions, never off duty for these. One attack of malaria only. Pleurisy 4 years ago, left side. Present illness: While at home in England 2½ years ago got an attack of liver. Returned to India at the outbreak of war and went to Mesopotamia in November, 1914. Kept well for the first six months. After that began to get diarrhoea, liver became enlarged and tender. Had rises of temperature also. *E. histolytica* found in stools. Given emetine, 7 doses of ¼ gr. each. Improvement on voyage home, but on arrival not feeling fit and liver still tender. Dr. Stevenson examined his stools and found active amoebae and cysts (*E. histolytica*).

**Examination.**—Slightly cachectic-looking, cheeks sunken, conjunctiva a fair colour. Lungs and heart nothing of importance. Liver enlarged, edge felt below costal margin, left lobe tender and felt hard. Spleen level of 9th–11th ribs. Urine: No albumin, blood, or sugar. Faeces: Free amoebae and cysts. *E. histolytica* (Stevenson).

**Diagnosis.**—Amoebic dysentery and amoebic hepatitis.

**Treatment.**—Emetine bismuth iodide, gr. 3 nightly, for 12 consecutive nights. (First part of course steartettes, latter part same crushed into powder.)

**Progress.**—The amoebae and cysts quickly disappeared from the stools and have not reappeared. The liver tenderness still persisted, however, a month and a half after the treatment. It is probable that this is due to adhesions having formed between the liver and diaphragm, or between the liver and adjacent viscera. The patient has improved in health and gained in weight, but is not yet normal.

Table V. gives the details of his faecal and blood examinations.

**3.—History.**—Patient (McG.), born in Scotland, went to Burma in 1912; in Rangoon in civil employment. Joined Army in 1914; France early in 1915; left there in December, 1915, and went to Mesopotamia, arriving in January, 1916. Invalided for jaundice and dysentery to Bombay; there two months, then sent home. Previous illnesses: Fever at times in Burma, no dysentery there, no venereal. Present illness: Dysentery in Mesopotamia. Seven to eight stools a day. No blood, mucus only; severe tenesmus. Given emetine four injections of 1 gr.; this stopped the dysentery at once, all symptoms disappearing. After this jaundice and abdominal pains. While in hospital at Bombay Widali negative to all typhoid group and nothing grown from stools; rigors and pain over gall-bladder, also bad pyorrhoea. Lately tendency to constipation and pain over gall-bladder region still.

**Examination.**—Heart and lungs nil. Tender over liver on deep percussion and also tender on pressure over lower border of liver in gall-bladder area. Liver enlarged both upwards and downwards. No tenderness over colon. Spleen not palpable. Blood examination: R., 5,000,000; W., 6000; Hb, 100 per cent. Differential count per cent.: Polymorphs, 63; mononuclears, 11; lymphocytes, 22; eosinophiles, 2; transitional, 1; mast cells, 1. Films: No malarial parasites. Urine: No albumin, blood, or sugar. Faeces: *E. histolytica* free, minute stage. *E. coli* cysts. *E. coli* cysts. No ova.

**Diagnosis.**—Amoebic dysentery carrier, amoebic hepatitis.

**Treatment.**—Painted tender area with lin. iodi. Course of emetine bismuth iodide, gr. 3, in powder in gelatin capsules for 12 consecutive nights.

**Progress.**—The patient took his first three doses without trouble, but was sick after the fourth. After this there was no further sickness, but a diarrhoea started, which, however, was easily controlled by tinct. opii. About the middle of the course the pain over the liver diminished and he felt better. On Jan. 23rd, the day after the course was finished, he passed some mucus in his stool and felt his liver a little,

Stearettes passed unchanged on Dec. 12th, 13th, and 15th.

while there was also a slight rise of temperature the same evening. The blood showed leucocytes 10,600 with no sign of malaria. Two days after, the pain over liver disappeared and up to the present has remained quiescent. Convalescence though somewhat slow has been sure and there is reasonable hope of a permanent cure. Table VI. shows the results of his treatment at a glance.

#### Convalescent Carrier Cases.

**1.—History.**—Patient (Ch.) joined the Army in 1914. Went to India in October, 1914. Stayed there till March, 1915, when invalidated home for heat-stroke. Before leaving also contracted dysentery. Treated for this on way home by emetine injections, four in all. Finally invalidated out of Army for epileptic fits. Present illness: After leaving Netley was treated at home by rest in bed and milk diet. Got much better after this. Afterwards went to Bournemouth, began ordinary diet, this being followed by diarrhoea and severe bleeding. Another relapse in October, 1915. Next two fits. Then another relapse of his dysentery. Treated by ipecacuanha, ? dose, and by more emetine injections. During 1916 bowels still very loose and anything easily upset him. Lately had constipation alternating with diarrhoea; pain in the abdomen as well.

**Examination.**—Heart sounds, nothing to note. Says he gets out of breath very easily if he takes any exertion. Lungs no signs of tubercle. Some pain over colon on deep pressure. Urine: No albumin, blood, or sugar. Faeces: *E. histolytica* cysts heavy infection, *E. coli* cysts; no flagellates, no ova.

**Diagnosis.**—Amoeboic dysentery, cyst carrier.

**Treatment.**—Emetine bismuth iodide, gr. 3, powder in gelatin capsules, nightly for 12 consecutive nights.

**Progress.**—Improved after course very much, all diarrhoea and pain disappearing. Patient also felt stronger and stated that he had never felt so well since acquiring his dysentery. Cysts disappeared rapidly from his stools after commencing treatment and have not reappeared (Table VII.). On Jan. 18th, 1917, an intensive daily examination of the faeces was begun, this lasting for over three weeks. Cysts have been absent during the whole of this period, and a permanent cure may be confidently anticipated. All symptoms have disappeared and the stools now are normal in number and consistence.

**2.—History.**—Patient (Q.), born in Newfoundland, joined Navy in 1910; been in it since. After war in Mediterranean chiefly. Present illness: At Tunis, Sept. 16th, 1916, seized with dysenteric symptoms, mucus, blood, and tenesmus, but not much straining. Went into hospital. Emetine 15 injections in all, ? dose. Much better after these. Stools now one or two a day, normal. Pain in abdomen occasionally.

**Examination.**—Some bad teeth. Heart and lungs nothing to note. Liver level of 6th and 7th ribs and costal margin; spleen level of 9th-11th ribs; no pain in abdomen. Urine: No albumin, blood, or sugar. Faeces: *E. histolytica* cysts, moderate infection; *E. coli* cysts, heavy infection.

**Diagnosis.**—Old dysentery, amoeboic carrier.

**Treatment.**—Emetine bismuth iodide, gr. 3, powder in gelatin capsules, for 12 consecutive nights.

**Progress.**—*Histolytica* cysts quickly disappeared (Table VIII.) from the stools and have not returned. The patient is well and now shows no signs of any abnormality in his bowels.

#### Relapsing Amoeboic Dysentery 26 Years after Original Infection.

**History.**—Patient (McL.) had acute dysentery in Egypt in 1890. Ten years later in England a relapse, treated by ipecacuanha, promptly recovered. Since that date until December, 1916, no intestinal disorders of any sort. Present illness: Started with an attack resembling influenza. Pain all over and aching bones. Then suddenly seized with all the symptoms of acute dysentery: blood, much mucus, great straining, abdominal discomfort, and passage of numerous stools. Faeces: Stools typically dysenteric, much blood and mucus. Amoebæ present, *E. histolytica*, minute stage, and *coli* cysts.

**Treatment.**—Stearlettes of emetine bismuth iodide, 3 gr. in each, were immediately begun. The symptoms at once responded to these, the amoebæ disappeared from the stools, also the blood and mucus, and the patient quickly recovered. As constipation set in during the middle of the course, one suspected the possibility of the stearlettes not dissolving, and an examination of the stool proved that this was so, three stearlettes being recovered quite unchanged. (This is the case referred to at the beginning of the paper.) That the first stearlettes did dissolve, however, is fairly certain, as there was considerable nausea after taking them and the symptoms cleared up so quickly. Since then there has been no clinical relapse. Stool examinations were only possible on three occasions after the end of the treatment. The case is reported to demonstrate the extraordinary chronicity of an amoebic infection.<sup>2</sup> Table IX. shows the treatment and faecal examinations at a glance.

<sup>2</sup> See also Brit. Med. Jour., Dec. 23rd, 1916, for details of another example.

A brief study of this series of cases shows that emetine given by the mouth, as emetine bismuth iodide, is apparently as efficient as emetine by the needle in cases of amoebiasis with liver involvement. Ipecacuanha used to act also, it is true, but one of its disadvantages was the sickness so often produced, this being badly borne by patients suffering from severe liver pain. These facts must mean that sufficient emetine is absorbed into the general circulation to act on the parasites in the liver, it being conceded, of course, that parasites are actually there when hepatitis, enlargement of the liver, and leucocytosis are present, the precursors of a definite abscess formation. The advantage of oral administration over hypodermic in such cases would seem to consist of the more potent sterilising powers ultimately shown by the double iodide on the amoebæ in the bowel, thus removing a possible source of subsequent reinfection of the liver.

Dobell has shown that in cases treated by emetine hydrochloride subcutaneously 70 per cent. relapse, whereas when emetine bismuth iodide is employed by the mouth this figure is reduced to about 10 per cent.; or stating this as regards cures, only 30 per cent. are got by the former, 90 per cent. or more by the latter. If, then, the latter can get rid of the acute symptoms satisfactorily and at the same time quickly, it is the best drug to use, as it is much more likely to sterilise the patient completely of his parasites in the bowel lesions at the same time. In cases of great urgency it might be advisable to give some injections first and then to follow these up by the oral method.

A point one may mention here, especially so as many people appear to entirely misunderstand it, is that the emetine does not kill the cystic stage of the parasite; it kills the amoebæ or active living forms which are present in the tissues of the bowel. The cysts in the faeces are being cast off, and only indicate that there are living amoebæ in the bowel producing them. If all the amoebæ are killed, then there can be no further production of cysts; the stools become negative and remain so permanently.

As far as one can judge, then, at present, emetine bismuth iodide holds out good hope of permanent cures in the different varieties of amoebiasis, in the sense that the patient is entirely sterilised of his amoebæ. The subsequent course of the disease will depend upon the extent of the original lesions—namely, the amount of bowel denuded of epithelium, deep ulceration producing peritoneal adhesions, strictures of the bowel, adhesions between liver and diaphragm, or between liver and adjacent viscera, and so on. Attacks of pain, bouts of diarrhoea, and definite colitis are not infrequent even after all signs of amoebæ have disappeared. The patient, it must not be forgotten, must be strictly dieted for a long period after his course of emetine; he must avoid wet and damp, and should abstain entirely from alcohol.

Some clinicians still prefer ipecacuanha in these chronic relapsing cases. In the old days the drug acted very well clinically, but in the light of modern research careful and prolonged faecal examinations would have to be made in order to determine the real value of such cures. If the emetine is the real essential in the ipecacuanha then a much larger dose can be given in a more convenient form by the use of the double iodide.

Finally, as regards dosage, if those who try the drug would attend carefully to the rules laid down for its administration there would be fewer disappointments. Some working standard must be adopted, and experience shows that that recommended by Dale of 3-grain doses every night for 12 consecutive nights (*36 grains in all*) is a good one. Dobell suggests that some cases may require an increased quantity, and in such the period may be extended even to 20 instead of 12 nights. Not less than *36 grains in all* should be given, as smaller quantities are generally followed by relapse. The case mentioned at the beginning of the paper (W., No. 3) is the only one, according to Dobell, that has been cured by so small a total as 15 grains in all—viz., 3 grains on five consecutive nights.

I have again laid stress on this dosage, as this has been misquoted and incorrectly stated, at least three times, in different journals.<sup>3</sup> It is to be hoped that those incorrect statements have not led people into errors in prescribing the drug.

<sup>3</sup> In an abstract of the paper by myself and Dobell (THE LANCET, August 19th, 1916) in the *Journal of the American Medical Association* (Sept. 16th, 1916, p. 908), again in the *Prescriber* (vol. xi., No. 24, January, 1917, p. 12), and, lastly, in the *Journal of Tropical Medicine and Hygiene* (Feb. 1st, 1917, p. 30) from subsequent papers by Dobell.

## A CASE OF PSYCHASTHENIA WITH CRIMINAL IMPULSES.

By W. NORWOOD EAST, M.D. LOND., M.R.C.S. ENG.,  
L.R.C.P. LOND.,  
MEDICAL OFFICER H.M. PRISON, MANCHESTER.

(With the Permission of the Prison Commissioners.)

WHILST states of psychasthenia are frequently met with, the psychasthenic with homicidal impulses would seem to seek medical advice early in the course of his disorder. It is exceptional for crimes of violence due to this condition to be met with in prison practice. For this reason the following case appears worth recording from the view of the medical jurist.

A single man, aged 33, a collier, was sentenced at a police court to one month's imprisonment or to pay a fine for assault on a woman. According to the evidence of the prosecutrix, a woman 25 years of age, while she was walking along a street she was suddenly attacked from behind by a man who put both his arms round her neck and threw her to the ground. Her head struck some railings as she fell. The man said nothing to her at all, and she had never seen him before. When she fell he seemed suddenly to realise what he was doing and went away, subsequently giving himself up at the police station and asking to be taken into custody.

The prisoner on admission into prison was 63½ inches in height and weighed 120 lb., which is much below the usual weight for his height (say 138 lb.), and also below his normal weight, which a year before was known to be 126 lb. He was in fair general health, but pale and somewhat anaemic. He had a high degree of myopia, for which he wore spectacles. He showed no evidence of recent heavy drinking and was quiet and peaceable in demeanour. His memory, attention, and perceptive powers were good, as were his judgment and reasoning capacities. There was no exaltation, and no delusions or hallucinations were detected. He was not unduly depressed. His pupils were equal and reacted normally. The knee-jerks were normal. He slept and ate well. Nothing of importance was learnt concerning the family. He was, for his station in life, fairly well educated. He had played truant at school and had been caned there for boyish faults. He had had no serious illness until, some six years before the offence for which he was detained, he had an attack of enteric fever. He was not epileptic, but perhaps was occasionally intemperate. He had never been in an asylum nor under certificates, and so far as was known had never been under mental observation before, unless this was so during his prolonged stay in the workhouse after the attack of enteric, when apparently he had written to a relation speaking of suicide. On leaving school he worked in a pit, and this was his chief occupation. He stayed at one place for four years and remained at others for lesser periods. Only twice had he been discharged by his employer. During the last six years, after the attack of enteric, his conduct had been less satisfactory. He did not keep his situations so long, at times only did casual work, spent varying periods in workhouses, and had been in prison once for begging. On four occasions he gave up his work owing, he said, to a feeling of restlessness. On these occasions he would wander about the country until the unsettled feeling had passed off. He was emphatic that he had not been drinking to excess on these occasions, and his memory was clear as to the events that then took place. The desire to ramble did not appear to be related to epilepsy. He stated that for a considerable time past he had felt a recurrent desire to kill people; it was variable in intensity, but he had sometimes difficulty in restraining himself. He had followed people with the idea of attacking them, but had never actually done so before. He was afraid to trust himself, and in prison felt safer and better able to control himself than when outside. After very careful consideration this condition did not appear to be related in any way to alcohol.

Prior to reception into prison for five months he had been working at a pit, earning 35s. a week, and living with a near relation. Four days before the offence the restless, unsettled feeling already mentioned as having occurred before, came on. He left work and visited towns in the neighbourhood. On the day the offence was committed he had, he stated, previously followed another woman with intent to attack her, but she evaded him. He followed the prosecutrix for some short time, feeling impelled to attack her and trying to restrain himself from doing so, eventually attacking her in the manner already described. In so doing his spectacles fell off, and possibly for this reason the attack was less serious than it might otherwise have been. He made no attempt at robbing or of indecent assault, and there was

no motive for his act. His memory was quite clear as to what took place; he realised that what he did was wrong, and fought against it. When the act was accomplished, however, he added that he felt easy in his mind. Being afraid that the impulse would again come over him he later gave himself up to the police. He stated that on the day he left his home and work he had too much to drink, but his memory was unaffected; the following days he was sober. It appeared, however, from close questioning that it was doubtful if he had been really intoxicated at all during this period. At each of several interviews he repeated the fact that the impulse to kill was very strong, that he had to fight against it, and that he felt no longer able to trust himself to combat it. Before his sentence expired his relations visited him and offered to take him home and keep him till he again got work, but he was afraid to trust himself and wished to be certified.

In determining whether his story was true or false the following points were considered:

1. The reason he gave for committing the crime was that which best fitted in with the known facts of the case as a whole.

2. No reason could be discovered as to why he should concoct a false account.

3. It would be extremely improbable that a man in his position in describing his condition should mention all the main characteristics of psychasthenic impulses—viz., recurrence, consciousness, painful mental conflict before, and sense of relief after, action, with full knowledge of wrongdoing, and retention of memory, unless he actually knew of this combination through his own experience.

4. His attitude and demeanour at the various interviews impressed observers as being genuine. He made them feel that he really was distressed at his condition and afraid to be in the world again with only his own will to prevent him repeating the act. This impression was strengthened by the fact that he would not accept his relations' hospitality on release.

5. He was anxious to be certified. The habitual criminal malingerers insanity to get transferred from prison to an asylum at times. The prisoner was not of this class, however, and the desire to be sent to an asylum at the end of a sentence instead of being released, apart from such, always suggests mental disorder.

6. He was a stranger, unknown in the district where the offence was committed, and could easily have got away. Instead he gave himself up to the police. A destitute man sometimes commits and admits a trivial crime to get arrested and the shelter of a prison, preferring it to that of a workhouse. A man wanted in one district for a serious crime may commit a trivial offence elsewhere to get arrested, thinking he may hide in prison. An offender sometimes confesses to a crime when he sees no opportunity of escape, hoping by so doing eventually to receive a more lenient sentence, or he may confess to a crime when drunk. Recently a man may commit a crime and admit it to get into prison to avoid military service. In this case the prisoner was not destitute, he had money on him when arrested, a home, and work to go to; he was not wanted for any offence in any other district; he was not drunk; he could easily have got right away and then would have required no leniency; finally, war had not been declared at the time. None of the ordinary reasons for confessing a crime were applicable in his case.

It does occasionally happen that a man commits a crime and informs the police, or courts arrest, when he feels he requires protection from himself—a melancholic subject recently under my care did this as he was afraid of committing suicide unless he was under restraint. Taking all the above facts into consideration, the account that the prisoner gave of the offence and of his impulses was considered to be genuine.

When a person is charged with a serious offence such as murder, and the evidence in the hands of the prosecution is so overwhelming that there is no probability of avoiding a conviction, the counsel for the defence, unable to combat the facts, may, and not infrequently does, raise a defence of insanity. This is at times successful, even when there are no medical facts to support it. A favourite suggestion the prisoner's counsel offers the medical witness to accept is that at the time of the crime his client was suffering from an insane impulse. Homicide frequently results from impulsive acts due to the alcoholic insanities, paranoia, melancholia, mania, dementia, and epileptic states, and these have always

to be excluded before such a suggestion is refused. The case recorded is one in which violence appears to have resulted from a homicidal impulse in one of the forms of mental disorder less commonly met with in this connexion in the criminal courts. It is perhaps fortunate that all the characteristics of psychasthenic impulses are not likely to be assumed by a person desiring to feign insane impulses to evade the consequences of serious crime.

## EXCISION OF THE RETRO-PHARYNGEAL GLAND,

WITH A SHORT ACCOUNT OF TWO CASES IN WHICH THIS OPERATION WAS CARRIED OUT.

BY NORMAN PATTERSON, M.B., B.CH. EDIN., F.R.C.S. ENG.,

ASSISTANT SURGEON, EAR, NOSE, AND THROAT DEPARTMENT, LONDON HOSPITAL; SURGEON, THROAT HOSPITAL, GOLDEN-SQUARE.

I HAVE performed the above operation on two occasions. The chief difficulty in removing the gland is its depth and near relationship to important structures.

It will be advisable to make a few preliminary remarks on retro-pharyngeal abscess, a condition frequently overlooked, especially in children.

Nearly all cases are due to suppuration taking place in the retro-pharyngeal lymphatic gland. (See diagrams.) There are two glands, one situated on either side of the middle line. Inflammation first occurs. This may be either acute or chronic (tubercular). Considerable swelling may take place, and clinical symptoms in rare instances will arise, before the formation of pus. (See Case 1.)

The abscess is, in the first place, confined to the gland; later, it bursts through the gland capsule. I have met with a tubercular abscess originating in the gland, where ultimately the abscess cavity extended from the base of the skull to the level of the thoracic inlet. In this case the larynx was markedly displaced forwards and to one side.

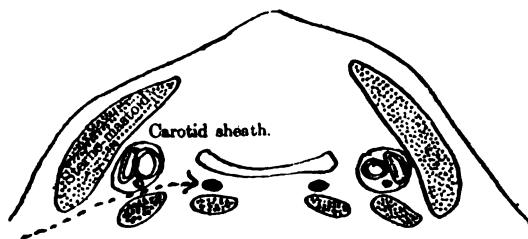

The question as to whether the pus is contained by the gland capsule or not is an important one in relation to treatment.

In dealing with acute suppuration the usual method is to open the abscess through the mouth; without doubt all tubercular abscesses should be opened from the neck. I would go a stage further and state that in some cases one ought not to be content with a mere opening and drainage of the abscess cavity, but when possible the diseased gland should be removed. (See Case 2.) I will now describe the procedure adopted in removal of the gland.

An incision is made along the posterior border of the sterno-mastoid. It starts behind the tip of the mastoid process and extends downwards for three inches or more. The deep fascia along the posterior edge of the muscle is divided. It is now possible to work inwards towards the pharynx between the sterno-mastoid on the one hand and the splenius capitis and levator anguli scapulae on the other. (See diagrams.) The dissection is now carried further inwards by separating the carotid sheath and its contents from their posterior relations. Any enlarged glands met with should be removed. In the neighbourhood of the pharynx there may be some venous haemorrhage. Great help can be obtained in the exposure of the gland by using strong retraction with a broad-bladed retractor. Without employing an undue amount of force the sterno-mastoid, carotid sheath, and even the larynx and pharynx can be pulled forwards. One of the risks is perforation of the mucous membrane. In order to avoid this the finger of an

assistant in the pharynx is of great service. During removal of this gland get the assistant to push it downwards and outwards towards the wound. By counter-palpation and the use of a blunt dissector the capsule is defined. Undue force must be avoided, as the gland may contain an abscess. By keeping close to the gland capsule and working in conjunction with the assistant there should be no real danger of perforating the mucous membrane. After removal

FIG. 2.

Transverse section, showing the position of the retro-pharyngeal glands. The arrow shows the line of dissection.

of the gland the skin is united by interrupted sutures. A small gauze drain should be inserted, otherwise blood may be extravasated into the cavity.

A different class of case (see Case 2) is that in which a tubercular retro-pharyngeal gland has broken down, with resulting infection of the surrounding tissues. A large abscess cavity may be present, causing a marked swelling in the pharynx and possibly in the neck.

In such a case the abscess is first of all evacuated through the neck, or the sac of the abscess may in exceptional circumstances be removed, with its contents, entire. Once the abscess cavity has been incised the opening should be enlarged. The walls of the cavity are inspected, and the gland which is probably present and in a caseous condition is removed. The abscess wall should now be carefully curetted, or it may even be possible to excise it. Packing will generally be required. The rate of healing will depend on the thoroughness with which the disease has been dealt with. If the abscess is a very extensive one, as in the case referred to above, repeated aspiration from the outside, either with or without a modified dissection, would probably be the best mode of treatment, coupled with fixation of the head and treatment on general lines.

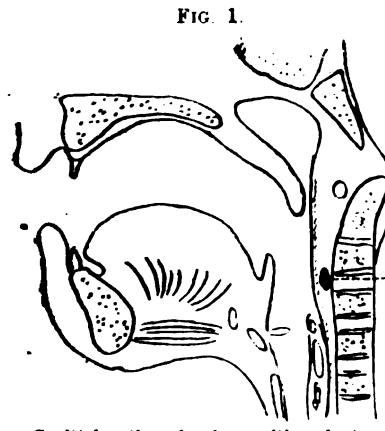

The following is a short account of the two cases where excision was carried out.

CASE 1.—Girl, aged 4. History of measles six weeks prior to admission. Ever since there had been increased difficulty in breathing, especially noticeable at night. There was a large swelling occupying the right side of the posterior pharyngeal wall and extending beyond the middle line. Operation was carried out shortly after admission to the London Hospital. When the swelling was palpated between two fingers it was so firm that I decided to remove it without ascertaining whether or not there was pus in its centre. The relief was immediate. Subsequent examination showed the gland to be of the inflammatory type; no evidence of tubercle was found, and there was no abscess. From the history and appearance I rather suspected tubercle. Union took place by first intention. In this case the formation of an abscess was forestalled by operation.

CASE 2.—Girl, aged 5. This patient had a large chronic retro-pharyngeal abscess which was opened in the usual way. Subsequently the pathological report confirmed the diagnosis of tubercle. An attempt was made to get the wound to heal from the bottom. Eventually the skin did unite, but shortly afterwards a swelling reappeared in the pharynx. The abscess was reopened, but notwithstanding every effort, failure was the result; the abscess re-formed. I decided to operate a third time. Through a much longer incision I thoroughly opened up and inspected the abscess cavity. At the bottom of it a caseous retro-pharyngeal gland was discovered and removed by dissection. In addition, the walls of the abscess were gently curetted. Healing was somewhat slow, but within a month the patient was discharged from hospital cured, and there has been no recurrence of the condition.

Since writing the above I have operated on a boy, aged 7 years, where recurrence took place a year and a half after the simple opening of a tuberculous abscess from the outside. The gland in this case was partly calcified.

Harley-street, W.

## THE PRINCIPLES OF THE TRANSFUSION OF BLOOD.\*

BY A. E. STANFIELD, M.D.CANTAB., M.R.C.P.LOND.,  
PHYSICIAN, METROPOLITAN HOSPITAL; SENIOR DEMONSTRATOR OF  
PATHOLOGY, ST. BARTHOLOMEW'S HOSPITAL.

THE idea of transfusing blood from the healthy to the sick has appealed to the imagination of our profession for centuries, but no considerable progress was made until recent years, owing on the one hand to the difficulties which the operation presented, and on the other hand to the dangerous reactions which sometimes followed the more successful attempts. But the revived enthusiasm for transfusion during the last decade in America, France, and Germany has finally established its value upon a sound experimental and clinical basis, and it is remarkable that the subject has received so little attention in this country. The whole of Europe has been preoccupied, however, during the last three years, and I may mention, therefore, that transfusion has been successfully employed in the treatment of various kinds of anaemia and in the arrest of spontaneous haemorrhage, whilst in combating serious infections and certain toxæmias, such as the toxæmias of pregnancy, promising results have been obtained.

How far the important factors of the blood concerned in achieving these various results reside in the serum it is not yet possible to say. So far as disintoxication and immunity are concerned transfusion may be merely a convenient method of transferring healthy or immune serum to the patient, and with the manifest domain of serum therapy I do not propose to deal. But blood therapy is still in its infancy : it could not be properly tested until an elaborate technique had been perfected and certain accidents liable to result from the chance admixture of different bloods had been excluded, and so with the remedy in our hands we have yet to learn exactly when and in what doses to use it.

### *Selection of Cases.*

The most obvious application of transfusion is to the treatment of anaemia, but there are as yet very few guides to the selection of suitable cases. The advantage of transfusion in the case of patients who have been rendered anaemic by recent haemorrhage is sufficiently clear ; but it is probable that the average existence of the transfused cells in the circulation of the recipient is not longer than 10 days even under the most favourable conditions, and therefore in cases of anaemia due to other causes the added blood, although it may serve to tide over a crisis, can do no permanent good unless blood formation is stimulated or blood destruction diminished in the patient's own body.

That an increased activity of the bone marrow frequently follows transfusion is demonstrated by the fact that the blood count usually rises with a simultaneous increase in the number of reticulated red cells. But when the condition of the peripheral blood indicates a hypoplasia of the bone marrow the only method of determining whether increased blood formation will result from transfusion is to transfuse and see. The following case is probably an example of simple stimulation of the bone marrow.

CASE 1.—The patient, a female aged 11 years, was admitted to St. Bartholomew's Hospital under the care of Dr. Morley Fletcher, suffering from a severe anaemia which had followed an attack of diphtheria eight months previously. No other cause than a simple hypoplasia of the bone marrow could be found to account for the anaemia, and as a result of the first six weeks' treatment the red cell count rose from 925,000 to 1,330,000 per c.mm., and the haemoglobin from 18 to 31 per cent. The patient then received 20 c.c. of blood from the house physician, and in 12 days the blood showed 1,580,000 red cells per c.mm. and 45 per cent. haemoglobin. 150 c.c. of blood were then transfused, and during the next 17 days the red cells rose to 3,000,000 per c.mm. and the haemoglobin to 63 per cent. Thereafter the anaemia diminished more slowly, until the patient went to a convalescent home.

In those diseases, such as pernicious anaemia, in which an excessive haemolysis is known to occur, it is difficult to determine how far improvement following transfusion is due to increased cell production and how far it may be due to

diminished haemolysis. That the latter is one of the factors concerned might be expected on clinical grounds, for, as with spontaneous remissions, the patient becomes less yellow and toxic in appearance, fever diminishes, and a feeling of well-being which is out of proportion to the change in the condition of the blood is soon experienced.

The observations of Wilbur and Addis,<sup>1</sup> Robertson,<sup>2</sup> and others have shown that the variations in urobilin output in cases of pernicious anaemia not only serve as an index of blood destruction, but correspond to the remissions and relapses in the course of the disease, whether these be spontaneous or attributable to treatment ; and Robertson<sup>3</sup> has shown that the remission following transfusion in a case of pernicious anaemia was accompanied by a corresponding diminution of urobilin excretion.

And, further, in some cases of pernicious anaemia the myeloid reaction becomes less evident as the patient improves after transfusion, suggesting that marrow hyperplasia is not wholly responsible for the improvement. This is illustrated by the following case :—

CASE 2.—Mrs. H., aged 42, suffering from pernicious anaemia with an enlarged spleen, was admitted to St. Bartholomew's Hospital under the care of Dr. J. H. Drysdale. Frequent examination of the blood suggested great haemopoietic activity, 4000 to 6000 normoblasts and 100 to 400 megaloblasts per c.mm. being constantly present, but in spite of all treatment the anaemia steadily increased, until, three months after admission, the blood showed 429,000 red cells per c.mm. and 19 per cent. haemoglobin. At this stage the patient, who had developed bronchitis, appeared to be moribund, but after receiving 250 c.c. of blood from her husband she showed a rapid and remarkable clinical improvement. During the next five weeks the blood count rose to 2,550,000 per c.mm. and the haemoglobin to 66 per cent., while the nucleated red cells steadily disappeared from the peripheral blood. The patient was then transfused again and she improved still further, the red cells reaching 3,850,000 per c.mm. and the haemoglobin 83 per cent. There were signs of relapse before she left the hospital at her own request 13 months ago, but it is now more than two years since the onset of the disease, and she is still able to look after her own home.

The ultimate prognosis in any case must depend upon the power of reaction in the bone marrow, and this, so far as I know, is only to be determined by trial. I have transfused 9 cases of pernicious anaemia, 8 of whom were selected because they were making no progress or were steadily becoming worse under other methods of treatment, the ninth being chosen because her condition was regarded as too serious to justify a trial of other methods. Of these 9 cases, 4 showed very marked improvement, 3, of whom 2 are still under treatment, showed definite but less marked improvement, 1 was merely kept alive for several weeks, and 1 derived practically no benefit. So far as these cases were concerned, the age of the patient, the duration of the disease, and the condition of the bone marrow as indicated in the peripheral blood proved to be the best guides to the progress subsequent to transfusion ; but in some cases the results far exceeded expectation, while in others they were disappointing.

### *Selection of Donors.*

The donor should be a healthy adult and the loss of such amounts of blood as I have generally used (250 c.c.) is never felt. In America larger quantities, even up to 1800 c.c., have been taken, and although such loss must debilitate the donor, there is probably no objection to taking as much as 500 c.c. at a time.

McClure<sup>4</sup> has recently recorded the transmission of syphilis from donor to patient. The donor, who had denied all possibility of infection, had a primary sore at the time of operation, and six weeks later both the donor and the patient, who was suffering from pernicious anaemia, simultaneously developed secondary eruptions. It seems unlikely that syphilis would be transmitted by a donor who, on careful examination, showed no signs of disease, but it is desirable that a Wassermann reaction should be done on the blood if time and facilities permit. In most cases, however, the donor is a relative or friend of the patient and he may be expected to answer questions frankly if the danger involved is explained to him. McClure also reports the transmission of malaria from a donor in whom the disease was quiescent to a patient in whom it flared up. But these two cases are the only instances I can find of the transmission of disease.

\* A paper read at the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on Feb. 20th, 1917.

If the prospective donor is found to be healthy his blood should be tested with that of the patient for iso-agglutinins and iso-hæmolsins. Landois,<sup>5</sup> in 1875, was the first to recognise the incompatibility of certain bloods, and Landsteiner,<sup>6</sup> in 1901, divided individuals into three groups according to the iso-agglutinative properties of their bloods. In 1910 Moss<sup>7</sup> recognised a fourth group, and the accompanying chart shows the reactions of the various groups.

CHART 1.

Group.	Serum agglutinates.	Corpuscles agglutinated by—
I.	Nil.	II., III., and IV.
II.	I. and III.	III. and IV.
III.	I. and II.	II. and IV.
IV.	I., II., and III.	Nil.

Chart 2 shows the result of testing together 12 specimens of blood. The first person belongs to Group I. and possesses no agglutinins, but his corpuscles are agglutinated by the serum of all the persons in other groups. The next four persons belong to Group II., the sixth to Group III., and the last six to Group IV. It should be noted that the fourth person (No. 4) slightly agglutinates the corpuscles of someone belonging to the same group, and it may be noted, too, that two of the specimens belonging to different groups, one in Group II. (No. 3), and one in Group IV. (No. 9), are from brothers. The technique employed in making these tests was that described by Dudgeon and Wilson.<sup>8</sup>

— = no agglutination. a = very slight but definite agglutination.  
AA = well-marked agglutination. AAAA = complete agglutination.

The four groups described have been supposed to be sharply defined, so that all bloods falling into one group are mutually compatible, while they are incompatible with all bloods in the other groups. It will be seen that if this were

true the group to which any blood belonged could be fixed by testing it against a known blood belonging to either Group II. or Group III. My own observations, however, show that a certain amount of overlapping of the groups occurs, and this is well illustrated by Chart 3, in which the first five persons belong to Group II., the next three to Group III., and the last to Group IV. The fifth person (No. 5) belongs to Group II., so that her serum agglutinates the corpuscles of the persons in Group III., but has no influence upon those of her own group. The corpuscles in this case, then, should be unaffected by the sera of Group II. and agglutinated by the sera of Group III.; but it was found that two of the Group II. sera produced slight agglutination, while of the Group III. sera one failed altogether to agglutinate, and the other two acted no more strongly than the sera of Group II. It is generally admitted, moreover, that different bloods contain different amounts, as well as different kinds, of agglutinin, and that the amount of agglutinin in a single blood may vary slightly from time to time. That these variations may be sufficient to obscure the true grouping of a particular blood is illustrated by the case of patient No. 9, who was transfused from the donor No. 8. (See Chart 3.)

CASE 3.—On Nov. 1st, 1915, a patient, C. S. (No. 9, Chart 3), suffering from pernicious anaemia under the care of Dr. A. Feiling in the Metropolitan Hospital, received 250 c.c. of blood from N.H. (No. 8) after the usual tests had shown the absence of agglutinins and hæmolsins. The red cells were immediately raised from 625,000 to 810,000, but a week later they had fallen to 600,000, and the patient appeared to have derived no benefit from the operation. There was, however, no unfavourable reaction of any kind. On Nov. 22nd the operation was repeated. When the patient had received about 20 c.c. of blood he complained of feeling faint, and became even more pallid. As the transfusion continued his pulse became very feeble, he retched and vomited violently, his face became distinctly puffy, and his skin was covered with cold sweat. When he had received about 100 c.c. he complained of pain in the sacral region, and this quickly became so intense that he could only be quieted with morphia. 250 c.c. of blood were given, and a few hours afterwards the patient began to pass hæmoglobin in the urine. Twelve hours later he was a deep yellow colour and slightly oedematous all over, but he said that he felt much better. The hæmoglobinuria ceased after 36 hours, the yellow colour and the oedema disappeared in the course of about three days, and the patient's general condition steadily improved until six weeks later, when he left the hospital for domestic reasons, he had just over 3,000,000 red cells per c.mm. and 75 per cent. of hæmoglobin.

[It is interesting to note the improvement which followed transfusion in the foregoing case in spite of immediate haemolysis of the transfused blood.]

Subsequent examination of the blood revealed the fact that the patient belonged to Group IV. and the donor to Group III., but apparently the corpuscles of the latter were not very susceptible to agglutination, and the titre of the patient's serum at the time of the first transfusion must have been so low as to give no agglutination by the ordinary tests. It appears, therefore, that a single examination is not always sufficient to establish the compatibility of two bloods on all future occasions.

There is no evident familial grouping of bloods. I have already remarked that two of the bloods in different groups in Chart 2 belong to brothers, and I have observed such differences in several other cases, but unfortunately opportunity has not permitted a further study for determining whether similarity and dissimilarity of blood reactions accompanies other physical features.

The group to which the blood belongs does not appear to be determinable at birth. Cherry and Langrock<sup>9</sup> recently examined the blood of 34 infants, each against the blood of its own mother, without finding a single instance of agglutination. Hektoen<sup>10</sup> states that the reaction of the child's blood is evident by the sixth year, and other observers have found the grouping to be apparent even before this, but it is useful to know that an infant may be safely transfused from its own mother without performance of the usual tests.

Hæmolsins are found less frequently than agglutinins, and it is established that they never occur without agglutinins. Ottenberg, Kaliski, and Friedman<sup>11</sup> experimenting on dogs found that hæmolsins were sometimes developed in the serum after repeated transfusions of agglutinable cells, but that they were never developed by the transfusion

of non-agglutinable cells. It is possible that the patient in Case 3 developed a haemolysin, or more haemolysin and more agglutinin, as a result of the first transfusion.

It has been noted by several observers that, as in Case 3, haemolysis following transfusion may be a much more violent phenomenon than haemolysis of the same blood *in vitro*, and even a slight degree of agglutination of the proposed donor's corpuscles should be viewed with suspicion, for the danger is not one to be lightly regarded. Bernheim,<sup>12</sup> collecting 800 reported cases of transfusion, found 15 instances of macroscopic haemolysis. Among these there were four deaths, three in cases in which no preliminary tests had been made and one in which it had been found that the donor's cells were slightly agglutinated by the patient's serum. There can be no doubt that a much higher proportion of disasters would have occurred but for the safeguard of preliminary tests.

Moss<sup>7</sup> showed that antihaemolysins are always present in blood the red cells of which are haemolysed by the serum of another individual. The presence of the antihaemolysin and the dilution of the transfused blood by the blood of the recipient probably explain the fact that it is less dangerous to introduce a blood containing haemolysins for the patient's corpuscles than to introduce one of which the red cells are destroyed by the patient's serum.

I know of no immediate phenomena resulting from the introduction of cells which are agglutinated without being haemolysed by the recipient, nor, indeed, is it known whether iso-agglutination occurs in the circulation. On one occasion, in the absence of a more suitable donor, I gave a patient 100 c.c. of blood the red cells of which he agglutinated. He was not benefited, but, on the other hand, he exhibited no unfavourable reaction. Nevertheless, it is undesirable to run risks by employing a donor belonging to a different group to the patient except in cases of extreme urgency, and then the risk will be least if the donor belongs to Group IV., so that his own cells cannot be agglutinated or haemolysed. Or if, in such cases, the grouping of the bloods of both donor and recipient is unknown and testing is impracticable, a small preliminary transfusion should be done half an hour before the main mass of blood is transferred, so that gross incompatibility may be recognised in time.

#### *Reactions following Transfusion of "Compatible" Blood.*

Even in those cases in which both donor and recipient have been found to belong to the same group febrile reactions are apt to follow transfusion. Among my own cases rigors have occurred in about 10 per cent., fever in about 25 per cent., and these figures agree closely with those published by most observers. The rigors have followed within half an hour of the transfusion, and the temperature in the febrile reactions, apart from the sudden rise accompanying the rigor, has usually reached a maximum of 102° to 103° F. on the following day, subsiding within 48 hours.

It has been suggested that the fever is due to incipient coagulative changes in the transfused blood, and some support is lent to this view by the fact that rigors are common after intravenous injection of defibrinated blood. Moss<sup>13</sup> noted rigors and transient fever in the majority of 75 cases which he treated by this method without other untoward results. But I have noticed a minute trace of coagulum remaining in my apparatus after transfusion on several occasions, although no reaction followed in the patient; and Lindeman,<sup>14</sup> in a series of 108 transfusions, observed that febrile reactions with or without rigors occurred much less commonly when the donor was a relative of the patient than when he was an "alien," and this although incompatibility due to agglutination or haemolysis had been ruled out in every case.

In some of my cases in which the patient has been transfused twice from the same donor a febrile reaction has followed the first transfusion but not the second; in other cases no reaction followed on the first occasion, while the second was succeeded by fever. But only in one case have the symptoms been at all alarming.

CASE 4.—The patient, aged 38 years, suffering from pernicious anaemia, was admitted to St. Bartholomew's Hospital under the care of Dr. Morley Fletcher. During a previous admission I had twice transfused him from his brother with marked benefit, the red cells rising from 500,000 to 3,800,000 per c.mm. and the haemoglobin from 16 to 86 per cent. during the course of seven weeks. He was now transfused with

275 c.c. from another donor, who had made a long journey for the purpose and whose blood had been found to be compatible a week previously. Within 15 minutes of the completion of the operation the patient had a rigor and his temperature rose steadily until it reached 105° F. three hours later. He became delirious and on the day following the operation the yellow colour of his skin was much deeper than before, but the blood serum showed no trace of haemoglobin. The most alarming symptom, however, was complete anuria, which lasted for 43 hours after the transfusion. The urine passed subsequently contained an excessive amount of urobilin, but not an unusual amount for a case of pernicious anaemia. The temperature fell slowly, reaching normal three days after the transfusion. But the subsequent rise in the number of red cells and the amount of haemoglobin was slight and transient, and the patient is about to be transfused again. Unfortunately, owing to the remoteness of the donor, I have been unable to repeat the agglutination tests in this case.

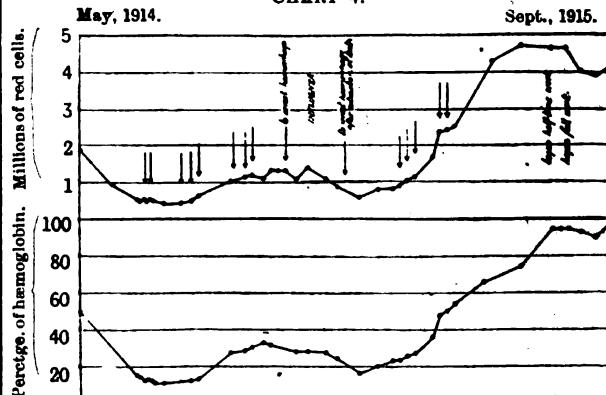

There are thus certain reactive phenomena which we cannot at present avoid, although the frequency of their occurrence is said to be diminished by the choice of close relatives of the patient as donors. The chief dangers may be eliminated by careful testing for agglutinins and haemolysins, but it may prove desirable to investigate other factors of which we as yet know nothing, not merely for the sake of avoiding accidents, but also to determine whether a given donor is likely to afford the maximum benefit in a particular case.

#### *Dosage.*

The amount of blood to be transfused depends upon the purpose of the transfusion, and in cases in which a considerable transfusion is proposed without the immediate object of increasing the red cell content of the blood it may be advisable to bleed the patient before the operation in order to avoid overloading the circulation.

For the arrest of spontaneous haemorrhage small doses of blood, even 20 c.c., will sometimes suffice, whereas in the treatment of acute anaemia due to haemorrhage the blood lost should be replaced as fully as possible, with due regard to the danger of dilating an enfeebled heart. But great uncertainty exists as to the optimum dosage in the treatment of chronic anaemias. There is a tendency now to the belief that large single transfusions are less beneficial, so far at least as stimulation of the bone marrow is concerned, than are small or moderate repeated transfusions, and I notice that the results which I have obtained in cases of pernicious anaemia with 250 c.c. doses compare favourably, even after a single transfusion, with those reported in America after such massive doses as 1000 c.c. or more. Careful and prolonged trial of different doses administered at various intervals is necessary before more can be said as to the best routine to employ, but the following case is interesting as illustrating the apparent value of very small doses.

CHART 4.

At each of the points indicated by an arrow the patient received 20 c.c. of blood. (The notes on the chart read from left to right: (1) to arrest hemorrhage; (2) influenza; (3) to arrest hemorrhage after extraction of teeth; (4) began half-time work; (5) began full work.)

CASE 5.—The patient, aged 38 years, was admitted to the Metropolitan Hospital on May 14th, 1914, under the care of Dr. Langdon Brown, suffering from haemorrhage from the nose and gums, extensive purpura, spontaneous bruising, and haematuria. No cause for the disease could be

discovered. The symptoms were of sudden onset, and the epistaxis and bleeding from the gums persisted steadily after admission in spite of treatment. After two months the patient's blood was reduced to under 500,000 red cells per c.mm. and 12 per cent. haemoglobin. At this stage small injections of normal blood were commenced, 20 c.c. being administered by syringe at intervals, as shown on the chart. The course of the anaemia will be seen. Progress was interrupted by a recurrence of spontaneous haemorrhage, by an attack of influenza, and by a profuse haemorrhage after extraction of several teeth, but a year later the patient returned to work with a red cell count of 4,700,000 per c.mm. and 95 per cent. haemoglobin. He has remained at work ever since and his general health is good, but the blood, although it contains 100 per cent. of haemoglobin, shows at present only 3,500,000 red cells per c.mm.

#### *Methods of Transfusion.*

The first consideration is to prevent coagulation of the transfused blood, the second to determine the amount which passes from donor to patient. The methods which have been employed may be classified as follows:—

I. Direct. By anastomosis of vessels, with or without a cannula.

II. Indirect. (i.) By syringe: (a) syringe transferred from needle in vein of donor to needle in vein of recipient; (b) syringe with two-way tap leading to veins of donor and recipient. (ii.) By use of a receiver: (a) with paraffin lining; (b) with addition of an anti-coagulant.

I have not attempted vascular anastomosis. The method is advantageous in avoiding exposure of the transfused blood, but it requires great surgical skill and the damage done to the blood-vessels employed is a serious drawback so far as the donor is concerned, while it may prove disadvantageous to the patient if the operation has to be several times repeated. And, further, no exact determination of the amount of blood transfused is possible.

The syringe method, popularised by Lindeman, requires two skilled operators, several other assistants, and a large number of expensive syringes which are easily broken. But given these various requirements the method is a good one. The mechanical difficulties in connexion with the two-way tap are very great. I have had several taps made, but finally discarded them in favour of a method employing a receiver. The paraffin-lined apparatus of Satterlee and Hooker<sup>15</sup> requires elaborate precautions, and coagulation is very liable to occur, whereas the use of an anti-coagulant renders transfusion a simple matter. Satterlee and Hooker<sup>16</sup> have employed hirudin to prevent coagulation with satisfactory results, but it is difficult to guarantee the absence of toxic substances in the hirudin, and serious symptoms have occurred in some of the later cases in which it has been employed.

Two years ago Weil<sup>17</sup> published his experiments on the transfusion of exsanguinated animals with citrated blood, and since then I have employed sodium citrate in 29 transfusions. At the same time it has been very extensively used in America and its convenience is generally recognised, although some workers assert that it has a toxic action when used in adequate doses. All the clinical as well as the experimental evidence is opposed to this assertion. Weil recommended a 10 per cent. solution of the citrate, which is sufficiently nearly isotonic with the blood to avoid causing haemolysis, and one part of this almost always prevents coagulation when mixed with 10 parts of blood. Smaller quantities of citrate will often suffice, but the higher proportion has, so far as I can determine, no disadvantages. Salant and Wise<sup>18</sup> have shown that the toxic dose of sodium citrate in dogs and cats is far greater than this, and Weil states that the coagulation-time of the recipient is actually lowered by transfusion of citrated blood. It may be questioned whether the citrate, by merely inhibiting the final stage in the process of coagulation, masks the preliminary stages which have in themselves rendered the blood toxic, but even if this is so, the dangers involved are not great and the value of the transfused blood is not evidently diminished.

The apparatus which I employ sucks the blood from the vein of the donor into a glass receiver, while a graduated stream of 10 per cent. solution of sodium citrate mingles with the blood as close as possible to its exit from the vein. When the required amount of blood has been withdrawn suction is stopped, the stream of citrate solution is cut off, the needle is removed from the vein of the donor and introduced into the vein of the patient, and the blood is gently

pumped from the receiver. By this method the time employed in withdrawing and transferring 250 c.c. of blood is usually about 15 minutes.

#### *Summary.*

1. Transfusion has been successfully employed in the treatment of various kinds of anaemia and in the arrest of spontaneous haemorrhage. It has also yielded promising results in cases of serious infection and in certain toxæmias.

2. The ultimate prognosis in cases of anaemia depends upon the power of reaction in the bone marrow, and this can only be adequately determined by observing the results of treatment.

3. In cases of pernicious anaemia both increased red-cell production and diminished red-cell destruction may result from transfusion.

4. In cases of pernicious anaemia the age of the patient, the duration of the disease, and the condition of the bone marrow as indicated in the peripheral blood have hitherto proved to be the best guides to the progress subsequent to transfusion.

5. The optimum dosage for transfusion is not yet determined, but it is probable that moderate repeated doses are preferable to large single doses in the treatment of chronic anaemias. Very small doses may sometimes be of value.

6. The donor should be a healthy adult with negative Wassermann reaction. The serum of the donor should not agglutinate the corpuscles of the patient, and the serum of the patient should not agglutinate the corpuscles of the donor. Agglutinins should be excluded by tests done immediately before the transfusion, and a single examination is not sufficient to establish the compatibility of two bloods on all future occasions. If agglutinins are absent, haemolysins will also be absent.

7. If there be great urgency and testing of the blood of patient and donor be impracticable, a small preliminary transfusion should be done half an hour before the main mass of blood is transfused, so that gross incompatibility may be recognised in time.

8. Febrile reactions occur after about 25 per cent. of transfusions, even though the bloods of donor and patient have been proved to be "compatible." Rigors occur in about 10 per cent. of the cases.

9. It may prove desirable to investigate the blood of donor and patient with regard to factors of which we as yet know nothing, not merely for the sake of avoiding accidents, but also to determine whether a given donor is likely to afford the maximum of benefit in a particular case.

10. The indirect method of transfusion, employing a glass receiver and sufficient sodium citrate to prevent coagulation of the transfused blood, is simple and involves no special dangers.

**THE SWEDISH ROYAL ACADEMY OF SCIENCE.**—Sir William Crookes, O.M., F.R.S., has been elected an Honorary Foreign Member of this Academy.

**ALEXANDRA NURSES AND MATERNITY HOME, DEVONPORT.**—The annual meeting of the supporters of this institution, which is in connexion with the Soldiers' and Sailors' Families Association, Devonport, was recently held under the presidency of Mrs. F. B. Mildmay; there was a large gathering. The report stated that during 1916 the number of babies born in the home was 153, against 96 in 1915. In addition, the nurses had attended 620 midwifery cases and 417 general cases. Rear-Admiral J. de M. Hutchison appealed for subscriptions from friends of the Royal Navy. The financial statement was satisfactory.

## THE TECHNIQUE OF THE PREPARATION OF CULTURE MEDIA CONTAINING ALBUMINOUS FLUIDS, IN PARTICULAR FOR THE GROWTH OF THE MENINGOCOCCUS.

BY P. FILDES, M.B., B.C. CANTAB.,  
ASSISTANT BACTERIOLOGIST TO THE LONDON HOSPITAL; WORKING  
ON BEHALF OF THE MEDICAL RESEARCH COMMITTEE AT THE  
ROYAL NAVAL HOSPITAL, MASLAB.

THE great advantage of the addition of albuminous fluids to media for furthering bacterial growth is, of course, well known, but the serious objection to their routine use has been the difficulty in sterilising them without altering their physical or nutritive properties. The alternative of collecting them in a sterile manner may be applied to blood or serum in small quantities from man or with special facilities in large quantities from large animals, but in the case of ascitic fluid the collection of a sterile specimen is notoriously difficult.

It may be assumed that the activity displayed in the past two years in the production of media for the growth of the meningococcus has some relation to the difficulty in obtaining sterile body fluids in large quantities, since it has long been known that blood agar, serum agar, and various preparations of ascitic fluid are more or less satisfactory for the growth of this organism.

When first interested in the preparation of sterile serum an attempt was made to reinforce the action of a volatile antiseptic by the application of slight heat. Dr. L. Rajchman and I thus published a note upon ether associated with mild heat, as suggested by Ori. In our method 3 per cent. of ether was added to the serum and the whole enclosed in a tightly stoppered bottle, which was placed in a water-bath for one hour at 45° C. and then 24 hours at 37° C.

By means of this method large quantities of serum agar have been prepared. It has, however, certain disadvantages. Sometimes a batch of serum is found not to have been sterilised, and when such refractory bacteria are present it is necessary to continue the heating in the incubator for days or weeks. Again, all bacteria are not inhibited by the ether in the cold, and some may grow in the bottles stored in the cupboard if they have been contaminated during any manipulation. For these reasons I tried the effect of chloroform in place of ether.

Chloroform has been used in the preservation of sterile serum for years and also in the sterilisation of such materials. In my hands, however, for the latter purpose it had proved unsatisfactory. If sterilisation was to be successful, it required at least months to effect. It, however, seemed probable that the application of slight heat which was insufficient to alter the delicate proteids even of whole blood might nevertheless greatly increase the bactericidal action of chloroform. A trial was therefore made with 0·5 per cent. chloroform upon some contaminated serum in a tightly stoppered bottle at 45° C. One hour at this temperature in a water-bath was found to sterilise it completely without in any way altering its appearance.

Chloroform has now been in use for 12 months, and during this time all serum and ascitic fluid have been sterilised with it. It has also been adopted for sterilising and preserving haemolytic and agglutinating sera. In view, however, of certain criticisms which the publication of the ether technique called forth, it may be desirable to mention that chloroform is only suggested as a *practical* method for preparing sterile serum for media. If serum is grossly contaminated with spores, it cannot be sterilised in one hour at 45° C. Slaughter-house blood is, however, not grossly contaminated with spores.

*The sterilisation of serum.*—The serum should be collected at a slaughter-house. The best animal to use is, of course, the horse, owing to the rapidity with which the corpuscles deposit, but for some time no horses have been available, and we have used ox blood. Unfortunately it is almost impossible to withdraw the serum from ox blood without the bulk of it being more or less heavily contaminated with corpuscles. We do not now attempt to get the serum absolutely free from corpuscles, but collect the whole as clear as possible and allow it to stand in the ice-chest in tall sterile jars about 2 in. in diameter. An efficient ice-chest

must be used for this purpose, because it may be necessary for the serum to stand as long as 14 days before complete deposition has taken place.

The jars should be examined after five days, when the corpuscles will be about half deposited. The clear serum should now be removed with a pipette or slowly syphoned off. Great care must be exercised in order not to disturb the corpuscles.

The separated serum is now distributed in measured quantities (200 c.c.) into glass-stoppered bottles (the fit of the stopper must be perfect) or into larger glass bottles. If the bottles of serum are to be disturbed, for instance in transit, it is better to fill them for despatch from a large bottle, otherwise on arrival they will be found to be "muddy" from the shaking up of a slight deposit caused by excess of chloroform in the bottle. Chloroform is added to each bottle to make 0·5 per cent. A drop of sterile oil is next applied to the stopper to prevent sticking and a dust-cover is fastened tightly over it.

The bottles are placed in the water-bath at 45° C. for one hour, being shaken occasionally. When they have cooled, a sample may be removed and mixed with agar to test sterility. This tube should be incubated for at least 5 days before sterility is assumed. We have not yet met with a sample of serum which was not sterile after undergoing this process, and it is recommended as a quick and certain method. It does not, however, leave the serum always unchanged; if the serum is red from admixture of lakèd corpuscles the colour tends to turn brown and darken. When the serum is required for any purpose entirely unaffected by heat, sterility may be obtained readily by placing the bottles in the air incubator at 37° C. and shaking occasionally. After 24 hours they will in most cases be found to be sterile, and almost invariably after 2 days.

When sterilised the bottles of serum are stored in a cupboard. Before the material can be used as a medium the chloroform must be removed, and unless this is done correctly the removal may not be efficient. The best way is to pipette the serum off in measured quantities (50 c.c.) into 200 c.c. flasks, and then to heat these flasks up to 55° C. rapidly and place them under the receiver of a pump. When a partial vacuum has been obtained, the receiver containing the flasks is shaken and the chloroform then boils off. If an exhaust pump is not available the flasks may merely be heated to 55° C. and thoroughly shaken. This, of course, will often soil the wool plug, but will not necessarily lead to bacterial contamination if non-absorbent wool is used. The serum is now ready to incorporate into a culture medium.

The chloroformed serum stored in bulk is very easy to handle and is not susceptible to contamination during the removal of samples. It is absolutely clear, but often a slight deposit collects upon the bottom of the bottle; this deposit is, however, compact and is not disturbed during the process of pipetting.

*The sterilisation of ascitic fluid.*—The ascitic fluid is collected from the patient into a large glass bottle and this is allowed to stand in the ice-chest for a day or two to permit the formation of any clot or gross deposit. The fluid is then decanted or filtered through glass wool. Ascitic fluid varies considerably in its reaction to litmus and thus should be brought to a slightly alkaline or neutral reaction with acid or alkali. The fluid is then distributed into stoppered bottles and chloroformed, the further treatment being exactly the same as for serum.

Ascitic fluid is always more susceptible to the formation of flocculent deposits during sterilisation than serum and these deposits are more easily disturbed during the removal of samples.

*The sterilisation of blood.*—Blood is collected at the slaughter-house in the same manner as serum, but instead of being allowed to clot it is defibrinated by stirring with a large wooden stick wrapped in gauze, the whole being previously sterilised.

In order to sterilise blood by the heat-chloroform method it is necessary to lake it before adding the chloroform. It is found that the bactericidal action of chloroform is quite inhibited when the fluid contains matter in suspension, and thus even 1 per cent. chloroform will not sterilise unlaked blood. For laking we have used both ether and distilled water and have found the latter preferable. An equal part of distilled water is added to the blood and the mixture distributed as in the case of serum. 0·5 per cent. chloroform is then added and the bottles well shaken.

While serum and ascitic fluid may be sterilised at 45° C., this temperature is not permissible in the case of blood, since a heavy precipitate forms after about 30 minutes. The bottles are therefore placed in the air incubator at 37° C. and constantly shaken. After 24 hours a sample is taken to test for sterility, and pending the result the bottles are not returned to the incubator, because the longer blood is heated the darker does the colour become. From the point of view of transparency in the subsequent medium the red colour of the blood should be retained as much as possible. Twenty-four hours is invariably long

enough to ensure sterility, the blood itself being practically sterile at the beginning.

This sterile blood is much more susceptible to the action of heat than serum; when, therefore, it is subsequently mixed with agar care must be taken that it is not heated above 55°C. and for as short a time as possible.

*The method of preparing media with sterile albuminous fluids.*—The media to which this method has been applied mostly are as follows:—

1. *Ascitic agar.*—Ordinary lemcō- (or meat-) peptone agar is prepared containing 2½–3 per cent. of agar. It is measured into 200 c.c. flasks in quantities of 150 c.c. and autoclaved. When required for use a flask of agar is melted in the steamer and treated in one of two ways:—

(a) It is poured into a sterile distributor maintained in a water-bath at 50°C. and a flask of ascitic fluid (50 c.c.) is added. The contents are mixed and then "tubed" through a "hooded" pipette to avoid contaminations.

(b) The flask of ascitic fluid may be poured directly into the melted agar in its flask and mixed and then rapidly poured either into Petri dishes or tubes. This latter method has the advantage of reducing the heating of the medium to a minimum, but requires more care.

It is important to mix the agar with the ascitic fluid (or serum) at a temperature as low as possible, since this results in a more transparent medium. This ascitic agar is as clear as ordinary agar, and has been found to grow the meningococcus admirably from the throat. Our samples have all contained blood, and this, together with nasal mucus, probably accounts for the excellence of the growth. In subculture this medium does not produce growths so profuse as serum agar.

2. *Serum agar.*—This medium is prepared in exactly the same way as ascitic agar, using serum. It also is no more opaque than ordinary agar. The meningococcus grows upon this medium in the great majority of cases, but sometimes inexplicably fails.

3. *Blood agar.*—An excellent transparent blood agar may be prepared by adding 25 per cent. of the sterile laked blood to 2½–3 per cent. agar. The finished medium thus contains 12·5 per cent. of blood.

4. *Blood-serum agar.*—This is the medium which we use for all routine work with the meningococcus except the primary cultures from throats. It contains a small quantity of laked blood, sufficient to stimulate growth but hardly sufficient to make any difference to the colour. We use 1 part of blood in 400 of medium, 1 c.c. of the laked blood (diluted 1 in 2) being added to each 50 c.c. flask of serum, or the blood may be added in bulk to the bottle of serum before this is distributed into flasks. In order to reduce the colour we use neither lemcō nor meat in the preparation of the agar, merely salt solution and peptone (Morson's).

The growth of the meningococcus upon this medium is profuse and one "slope" is sufficient to supply emulsion for carrying out, for instance, a set of agglutination tests with five different sera. Other delicate pathogenic organisms, such as pneumococci and streptococci, also develop abnormally large colonies upon it.

#### A CASE OF

### SHELL-WOUND OF THE HEART CAUSING COMPLETE HEART-BLOCK.

BY C. EDGAR LEA, M.D. VICT., M.R.C.P. LOND.,  
LATE CAPTAIN, R.A.M.C.; HONORARY PHYSICIAN, ANCOATS HOSPITAL,  
MANCHESTER.

I AM indebted to Captain J. Morley, R.A.M.C. (T.), for the opportunity of seeing and recording this unique case, which presents problems alike in regard to causation and treatment.

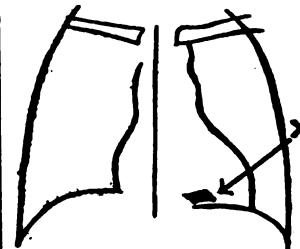

The patient, a soldier, aged about 20, received a wound over the heart region on July 1st, 1916, probably by a portion of shrapnel. I saw him first in December, 1916. The wound had completely healed, but there was some shortness of breath on exertion. He never had any syncope attacks of any kind; nor had he any pain. The heart's dullness was increased to the left and probably to the right. There was a soft systolic murmur over the apex. The rhythm was regular; the rate slow, 40 per minute. This did not vary with effort. Previous X-ray examinations had shown the presence of the fragment in the immediate vicinity of the heart, and he was admitted with a view to considering the possibility of operation for its removal. A screen examination which I made showed that the fragment was in the position shown in Fig. 1. It distinctly moved in an upward direction with the ventricle at each systole. It was probably in the myocardium or in the substance of the pericardium, which was probably adherent over this site. The heart, too, appeared much

larger than had been suspected from percussion. Immediately after the screen examination an electro-cardiographic curve was gained (Fig. 2), typical of complete heart-block. The auricles (rate 96) are beating quite independently of the ventricles (rate 40).

The notes are, unfortunately, very brief, owing to the exigencies of military conditions, and the patient was only under my personal observation for a few days; nor have I been able to get any notes either previous or subsequent to this occasion. He has been lost sight of entirely.

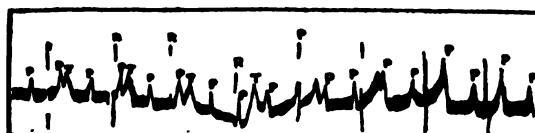

Two problems are presented in this case: What is the relation of the wound to the blocking, and secondly, what treatment could be advised? As regards the first, there seems little reason to doubt that the heart-block was induced by causes immediately associated with the wound. He had up to the date of its reception been perfectly well, and so slow a pulse previous to this occasion would not have passed unnoticed. It is, we think, anatomically impossible for the bundle of His to have been directly damaged by the fragment, situated as it is in the very centre of the heart, whereas the fragment is on the outer aspect of the myocardium and nearer the apex than the base of the heart. The only explanation we can suggest is that the mechanical shock to the heart due to the wound caused at the same time a small haemorrhage which implicated the auriculo-ventricular

FIG. 1.

Diagrammatic, to indicate roughly the site of the fragment (x) situated near the diaphragm on the left side. It moves synchronously with the heart at each systole.

FIG. 2.

Electrocardiographic curve showing typical complete heart-block.  
P = auricular systole; R T = ventricular systole.

bundle. It is a structure with a fairly good blood-supply, and it is embedded in tissues of some rigidity, which would offer, therefore, a relatively greater resistance to a mechanical blow.

As to treatment, medical measures are obviously of little avail. Atropine had no effect in relieving the block, and if one is right in considering the cause as traumatic, drugs such as potassium iodide could offer no satisfactory prospects. Operation would be equally helpless in removing the block. That in an ordinary case the fragment could be successfully removed we have little doubt; the war has shown this. But would a surgeon like to operate upon a case complicated, as this is, by a severe functional disorder? Though hitherto this patient had had no syncopal attacks, it by no means follows that such an event might not be induced under an anaesthetic. But here we have no experience to guide us; we have noted, however, that the intravenous injection of salvarsan, a relatively trivial affair, has been followed by rather startling symptoms in the few occasions in which it has been tried in cases of heart-block. And even were the fragment removed, it is doubtful whether the full functional efficiency of the myocardium, already seriously impaired as shown by the dyspnoea and the cardiac enlargement (neither condition necessarily associated with pure heart-block), would be restored or much alleviated.

Manchester.

**SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.**—The report read at the annual meeting, recently held under the presidency of Viscount Clifden, stated that during 1916 1672 in-patients and 1793 out-patients had been treated. The treasurer reported a year of "unprecedented financial anxiety," as the ordinary expenditure for the year exceeded the ordinary income by £3190, and the committee appealed for increased subscriptions so that the work of the hospital might not have to be curtailed for want of funds.

## METABOLISM IN GOUT.

BY WILLIAM BAIN, M.D. DURH., F.R.C.P. LOND.

From the Physiological Laboratory, King's College, London.)

Two early and important discoveries focussed the attention of the profession on the problem of the exact relationship of uric acid to gout. In the first place, Wollaston showed that a salt of uric acid was deposited in the tissues of many gouty patients; and, secondly, Garrod demonstrated that an increase of uric acid commonly occurred in the blood of such subjects. The issue raised was, and is, whether uric acid is the essential cause of the disease or merely an agent incidental to its pathology. An immense amount of work has been done to clear up the point, and although the effect of this and allied investigations has been to modify some current theories and to falsify others, no decision has yet been reached: the pathology of gout still remains hypothetical as regards its causative factor. Under these conditions further research on the beaten track seemed desirable, and this consideration led me to investigate the calcium metabolism in gout. It is well known that calcium is a regular ingredient of gouty deposits, and in some analyses of tophi I found that the murexide test failed to reveal the presence of uric acid. Before describing the methods, conditions, and results of the investigation it is advisable to state briefly what is known regarding the excretion of calcium in health and in some diseases.

## General Considerations.

Calcium is taken into the organism in both inorganic and organic form. Its principal inorganic salts in food are the phosphate, sulphate, and carbonate. Organic combinations are believed to occur in milk, eggs, and vegetables. The absorption of calcium largely depends on the salts present; thus associated sodium chloride raises the absorption of calcium, and the latter is also affected by the phosphorus intake, because the formation of insoluble calcium phosphate may retard absorption. The precise needs of the human organism relative to calcium are still undetermined. H. Oberndorffer<sup>1</sup> puts the figure at 1.5 grammes per diem, whereas Bunge<sup>2</sup> gives 3.5 grammes as the required daily quantity. It is probably safe to say that a diet containing less than 1 gramme of calcium oxide per day is deficient in calcium. Widely different statements are made as to the calcium content of the blood under normal conditions. Bunge<sup>3</sup> puts it at 0.04 per cent. of calcium oxide, but others give figures as high as 0.27 per cent. No doubt the content is related to the amount in the diet, and doubtless the same is true in pathological conditions; Hirschler and V. Terray<sup>4</sup> found in a case of chronic endo-arteritis on a mixed diet 0.0051 per cent. of calcium oxide in the blood, which sank on a milk diet to 0.0027 per cent.

Of the total intake by far the greater part is voided with the faeces, only about 10 per cent. being excreted in the urine (Sherman).<sup>5</sup> In Vierordt's Tabellen (p. 237) the daily output of calcium oxide in the urine is given as 0.2 to 0.3 gramme. This is the average of several analyses. In osteomalacia there is a pronounced loss of calcium, and there is more calcium in the urine than in the faeces. On the other hand, in osteitis deformans a marked retention of calcium in the body occurs, and the proportion excreted in the urine is greatly diminished.<sup>6</sup> In wasting diseases the urinary calcium rises. It has been shown experimentally that the administration of soluble calcium salts, or of acids (such as lactic) which yield soluble calcium salts, increases calcium excretion via the kidneys.

Previous studies of metabolism in gout do not appear to have touched upon calcium as a factor, but, as already stated, have been mainly concerned with uric acid; and in relation to this substance Garrod's observation that there is an increase in the blood has been corroborated by other workers. Gudzent<sup>7</sup> found that the blood may contain as much sodium mono-urate as, or more than, it can hold in solution (8.3 mg. per 100 c.c. of blood), so that there is

a relatively supersaturated solution of the lactim form of urate; even on purine-free diets gouty blood contains an excess of uric acid independently of acute attacks. This conclusion has been confirmed since the introduction of Folin's<sup>8</sup> new method of estimating uric acid.

Irregular periods of nitrogen retention and loss are quite frequent features in gout. The cause of the variations is uncertain, although it is probable that the major part is accounted for by purine retention; most of the excessive loss occurs during acute attacks (Brugsch<sup>9</sup>). The statements respecting phosphorus metabolism in gout are varied and contradictory, but there does not appear to be any pronounced variation from the normal. In view of the ascertained fact that the calcium coefficient, particularly in respect of the urine, depends on the intake, it was essential during observations to prescribe a fixed diet of known composition.

## Present Observations.

The following, briefly, are the methods employed in my analyses of urine, faeces, and foodstuffs. Phosphorus was estimated by Neumann's method; moisture by drying at 100° C. and weighing to constant weight; uric acid by the method of Folin and Shaffer; calcium by Aron's method; and total nitrogen by Kjeldahl's method. These are standard methods, and do not therefore need description. It should be added that Aron's method<sup>10</sup> for calcium was found quite trustworthy when applied to foodstuffs, blood, and faeces, but in the case of urine gave results which were too high. Professor Spiro kindly informed me, on inquiry, that he had found the method inaccurate in the analysis of the urine because of the large amount of alkali sulphates thrown out of solution on the addition of alcohol and weighed with the calcium sulphate. He said he had modified the method as follows: Take 500 c.c. of urine, evaporate down to 150 c.c. and then add ammonia and ammonium oxalate sufficient to precipitate all the calcium present. Allow the vessel to stand one or two hours and decant the fluid through a folded filter. Return the filter to the flask and oxidise by Neumann's method. After this process quantitatively transfer it to a beaker and precipitate the calcium sulphate with three to four volumes of 40 per cent. alcohol. The precipitate is washed, dried, and finally weighed in a Gooch crucible. This is the method I adopted for the urine, except that 95 per cent. alcohol was used, as it was found that in 40 per cent. strength it was insufficient to cause complete precipitation.

## Diet.

The two cases investigated were in hospital simultaneously and received the same diet, the following being the daily regimen: Bread, 395 gms.; butter, 55 gms.; sugar, 30 gms.; oatmeal porridge, 298 gms. (weighed after cooking 55 gms. of Quaker oats); meat (beef), 100 gms., weighed after cooking; potatoes, 260 gms. weighed after cooking; milk, 1 litre; Salutaris water, 500 c.c. (calcium-free). The porridge was made with 400 c.c. water; 600 c.c. of water were also taken in the form of weak tea. The following figures summarise the analyses for nitrogen, phosphorus, and calcium in the diet. Each is the mean of two or more analyses:

	Nitrogen.		Phosphorus.		Calcium.	
	Per cent.	Gms. in daily food	Per cent.	Gms. in daily food	Per cent.	Gms. in daily food
Bread ... ...	1.15	4.58	0.16	0.64	0.017	0.08
Milk ... ...	0.5	5.0	0.027	0.27	0.16	1.6
Butter ... ...	0.14	0.07	0	0	0	0
Meat ... ...	3.72	3.72	0.42	0.42	0.024	0.024
Potatoes* ...	0.30	0.78	0.09	0.24	—	—
Oatmeal ...	0.29	0.86	0.20	0.60	0.087	0.25

\* No estimation of calcium in potatoes was made. Bunge in his tables (*Physiol. d. Menschen*, II, 88) states that 1000 gms. of potatoes contain 1 gramme of calcium oxide.

## Clinical Data.

Before going on to consider the composition of the urine and faeces, it will be convenient to describe briefly the clinical condition of the two patients.

<sup>8</sup> Folin and Denis: Journ. Biol. Chem., XIII, 469, 1913.

<sup>9</sup> Zeitsch. Expt. Path. Ther., 1906, 619.

<sup>10</sup> Biochem. Zeit-ch., IV, 268, 1907.

**CASE 1.**—The patient, a man aged 49, had suffered from gout for 22 years, first in the big toe and subsequently in many other joints, and had tophi in the ears and fingers. He used to take a large amount of cheap beer, and to eat a lot of meat. He was subject to attacks about once a month, and his last attack, in the big toe, had begun five days before admission. His systolic blood pressure was 210 mm. Hg; the specific gravity of the urine was 1015; there was a small amount of albumin present in the latter and also a few casts. There was no cardiac murmur. He had no acute attack during his stay in hospital and was free from pain.

**CASE 2.**—The patient, a man aged 40, suffered from a first attack of gout in a big toe about 12 years previously and had had frequent attacks thereafter, with the pain flitting from joint to joint. The existing attack began about two months before admission. The various attacks had affected nearly all the joints with the exception of the shoulders. Subsequent to admission two joints, the left big toe and left wrist, had been affected. No cardiac murmurs, no albuminuria, small tophi in ears; systolic blood pressure 160 mm. Hg.

**Excretions.**—Both of the above patients were under observation from Feb. 17th to March 9th. From Feb. 24th to March 3rd (eight days) they received no calcium except what was in the food; from March 4th to 6th (three days) they took extra calcium in the form of calcium chloride equivalent in terms of calcium oxide to 0.735 gm. in the 24 hours. The urine and faeces were analysed each day, and the following table gives the daily averages of the two periods (A) without and (B) with the calcium chloride addition.

TABLE I.

	Nitrogen in gms.				Phosphorus in gms.				Calcium as CaO in gms.				
	Food.	Food.	Urine.	Faeces.	Food.	Food.	Urine.	Faeces.	Food.	Food.	Urine.	Faeces.	Balance
Case 1 { A	14.9	15.1	2.5	-2.7	2.1	2.1	1.1	0.9	+0.1	2.0	0.13	2.3	-0.4
	15.0	11.7	1.4	+1.9	2.1	2.1	1.07	0.5	+0.4	2.73	0.14	1.47	+1.1
Case 2 { A	14.9	10.7	1.6	+2.6	2.1	2.1	1.04	0.34	+0.72	2.0	0.14	1.3	+0.8
	15.0	7.4	1.5	+6.1	2.1	2.1	0.86	0.4	+0.84	2.73	0.11	2.14	+0.4

A sample of blood was taken from the two patients the day before they left the hospital and analysed. In Case 1 the blood calcium content was 0.071 per cent. calcium oxide; in Case 2 it was 0.062. From these figures it will be seen that the administration of calcium chloride was accompanied by a retention of nitrogen; there was little or no change in phosphorus metabolism, and with regard to the calcium it led in the first case to retention of that element, and in the second the retention which occurred previously to taking the calcium salt was diminished. The change, however, in either direction was not large, and the calcium content of the urine remained unaltered in both cases. The result, however, which most interested me was the effect upon uric acid excretion in the urine, shown in Tables II. and III.

TABLE II.—Uric Acid Excretion in Grammes.

Case 1.

Case 2.

Before adminis- stration of calcium chloride.	During adminis- stration of calcium chloride.	Before adminis- stration of calcium chloride.	During adminis- stration of calcium chloride.
0.64	0.43	0.31	0.17
0.65	0.32	0.24	0.13
0.66	0.36	0.23	0.12
0.62		0.31	
0.42		0.28	
0.55		0.16	
0.54			
Mean 0.61	Mean 0.37	Mean 0.28	Mean 0.14

It will be observed that there is a marked decrease in the uric acid output during the administration of calcium. In two other somewhat similar cases (long-continued gout with fairly frequent acute attacks), taking the same fixed diet, I found a like effect upon the uric acid output produced by

the administration of calcium chloride (10 grains three times a day).

TABLE III.—Uric Acid in Grammes.

	Case 3.	Case 4.
Before giving $\text{CaCl}_2$ (5 days)	0.12	0.062
During administration of $\text{CaCl}_2$ (4 days)	0.10	0.012
After administration of $\text{CaCl}_2$ (2 days)	0.15	0.083
During administration of atophan (3 days)	0.33	0.188
After administration of atophan (1 day)	0.17	0.093

I am unable to offer any explanation of this effect of a soluble calcium salt upon the uric acid output. It can scarcely be regarded as beneficial, although in only one of the four cases was it accompanied by any return of joint pains. My opinion, based upon clinical observation, is that the lime salts tend to aggravate gouty manifestations, and that a restriction of the foodstuffs containing more than moderate quantities of calcium is advisable, especially in tophaceous gout. I have added in the foregoing table the effect of atophan on the excretion of uric acid in these two cases. This drug produced the usual increase in the uric acid output. There are, however, exceptions to this rule. In my private practice a case occurred where the excretion of uric acid was markedly diminished on two occasions by the administration of atophan. On the first occasion the daily output of 11.38 grains was reduced to 6.9, and on the second from 14.63 grains to 5.7. Judging by this result it is necessary to estimate the uric acid output during the exhibition of atophan.

It may be of interest to append the calcium content of those foodstuffs which contain more than a minimal amount of this substance. The figures are taken from A. Neuberg's statistics.<sup>11</sup>

TABLE IV.—Calcium Content of Foodstuffs.

Foodstuff.	Total ash. %	CaO % in ash.	CaO in 1000 gms. of food-stuff.	Foodstuff.	Total ash. %	CaO % in ash.	CaO in 1000 gms. of food-stuff.
Spinach ...	16.48	11.87	19.6	Endive ...	16.18	12.03	19.5
Celery ...	11.04	13.11	14.5	Oatmeal ...	2.8	7.42	2.08
Rhubarb ...	14.44	10.04	14.6	Plasmon ...	8.69	32.68	2.85
Cow's milk	0.72	22.42	1.62	Quaker oats	3.14	3.73	1.10
Cheese, Parmesan {	6.29	34.72	2.18	Brown bread {	2.27	1.12	0.25
Pork ...	4.06	7.53	3.06	Potatoes ...	3.79	2.64	1.00

Drinking water is at all times a source of calcium in the diet, and in certain districts this may reach a high figure.

To Dr. F. W. Mott and Dr. William Hunter I must express my sincere acknowledgment for taking the cases into their wards in Charing Cross Hospital. I must also thank Professor W. D. Halliburton for affording me every facility in his laboratory, and my assistant, Mr. J. C. Drummond, B.Sc., for doing the major part of the work.

#### Summary.

1. The excretion of calcium in the urine of gout is lower than the accepted normal. However, the urinary content forms, as is usually the case, a small fraction of the total output, most of the calcium leaving the body via the faecal excrements.

2. The effect of administering calcium chloride in two cases of gout, kept on a fixed diet, was to cause a slight retention of nitrogen, but the phosphorus metabolism was practically unaffected.

3. The effect on total calcium metabolism was not constant. In one case a small negative calcium balance was transformed into a small positive one; in the other the positive calcium balance was reduced. In both cases the urinary calcium was not affected.

4. In the four cases observed the giving of calcium chloride produced a marked fall in the uric acid output in the urine. The explanation of this observation is not at present forthcoming; it suggests that the administration of food rich in calcium should be restricted in cases of gout.

## JOURNALS.

*Quarterly Journal of Medicine.* Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GABROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. X., Nos. 37 and 38. October, 1916, and January, 1917. Oxford : At the Clarendon Press ; London, Edinburgh, New York, Toronto, and Melbourne : Humphrey Milford. Subscription price, 25s. per annum. Single numbers, 8s. 6d. net each.—The contents of this number are : 1. Septicæmia due to *Moroccoccus tetragenus* as a Cause of Pyrexia at the Front, by A. H. Birks, R. T. Thornley, and R. A. Fawcett. From a study of obscure cases of pyrexia occurring at the front at the present time the authors conclude that a large proportion of all these cases are septicæmias which fall into two general types, one clinically resembling paratyphoid, the other being called "trench fever." The most common of these septicæmias is tetragenus fever due to the *Moroccoccus tetragenus*. These cases appear to have some characteristic features—namely, a sudden onset, headache, and pains in the lumbar regions and down the legs, with tenderness over the tibia. Anæmia is common and lethargy is the most characteristic mental state. 2. A Study of the Metabolism in a Case of Amyotonia Congenita, by F. Powis and H. S. Raper. A case of this condition is described in a girl aged 4 years, upon whom metabolic investigations were made in three separate periods of five days each. The chief conditions noticed were a diminution of hepatic functional activity manifested by the presence of acholia, a normal calcium retention with a relatively high potassium retention, and a low creatinine excretion with a relatively high creatine excretion. The authors state that they have published this account of a single case in order that other investigators may be able to confirm or disprove the constancy of these abnormal features. 3. Records of Speech in General Paralysis, by E. W. Scripture. An interesting study of the speech difficulties in general paralysis investigated by means of a special recording apparatus is here presented. An analysis of the records obtained apparently calls for very minute investigation, so that a single sentence may require something like five hours to analyse, but the results obtained throw an interesting light upon the nature of the speech disorders. The chief condition observed is one to which the name asphasia is applied as a substitute for the misleading one of cortical ataxia, to indicate a lack of precision in speech. Dr. Scripture finds that asphasia is an early symptom in the record of the general paralytic, whereas it never occurs in neurasthenia. 4. The Retinitis of Arterio-sclerosis, and its Relation to Renal Retinitis and to Cerebral Vascular Disease, by H. Foster Moore. This paper is based upon a careful examination of the clinical and ophthalmic conditions found in 66 patients seen at Moorfields Eye Hospital and 44 seen at St. Bartholomew's Hospital. The changes in the retina and its vessels occurring in arterio-sclerosis are carefully recorded and their relative importance discussed. The work of Marcus Gunn upon the same subject is confirmed and extended. Next Mr. Foster Moore brings forward evidence tending to establish the existence of an arterio-sclerotic retinitis as a clinical entity. He then studies the relation of sclerosis of the retinal arteries to cerebral arterio-sclerosis, which he regards as both striking and conclusive. The paper is illustrated by some admirable drawings and coloured plates. 5. On the Early Stages of Wounds in the Chest. Cases of chest wounds have been studied by Colonel Sir W. P. Herringham at a casualty clearing station near the front. Unless a case shows symptoms of sepsis, or has some complication rendering it more severe than usual, it has been found by Sir W. P. Herringham best to send the case back to the base when 72 hours have been completed from the time that the wound was received. Of 211 consecutive cases, 22 died at the clearing station and the remainder were evacuated to the base. Haemothorax is almost always present. Congestion of the opposite lung apparently occurs very frequently, but is only dangerous if it is of large extent and the wounded lung is useless. 6. Jaundice of Infective Origin, by Colonel Sir Bertrand Dawson and Colonel William E. Hume. This paper deals with jaundice due to a spirochæte, and it is differentiated from other forms of infective jaundice. It is illustrated by several excellent coloured plates and is an important contribution to the subject with which it deals. This paper has already been noticed in a leading article in THE LANCET of Feb. 3rd, 1917. 7. Lipodystrophy

Progressiva, by Dr. F. Parkes Weber. A critical review with a bibliography of this rare and interesting condition is given, and its pathology and relation to other disorders of the subcutaneous fat are discussed.

*Journal of Nervous and Mental Disease,* February, 1917.—This number contains full reports of meetings of the New York and Boston Neurological Societies at which last summer's epidemic of poliomyelitis was discussed at great length from various points of view. At the Boston Society statistics were given showing that 90 per cent. of cases were under 5 years of age and 4 per cent. over 15. The total mortality was 19.5 per cent., and the mortality figures were notably higher during the first half of the epidemic than during the second half. Dr. Edwin H. Place mentioned his results with immune serum, of which 10 c.c. doses were given two or three times in 24 hours. Three of 8 preparalytic cases treated with immune serum developed paralysis, while of 16 preparalytic cases not treated only 1 developed paralysis. Of 40 cases in which immune serum was administered 52 per cent. died; in 33 per cent. there was extension of paralysis, in 15 per cent. no extension. As chiefly the most desperate cases were treated with serum the poor results may perhaps thus be explained. As regards diagnosis at an early stage, obviously a matter of the first importance, several speakers discussed the significance of changes in the cerebro-spinal fluid. In the prodromal stage of from one to four days, while there may be little clinically to attract attention, the fluid may show gross alterations from the normal. In a series of cases recorded by Dr. Francis W. Peabody the fluid was found to be under increase of pressure, and cytological examination showed an average of 300 cells per c.mm., of which from 80 to 90 per cent. were polymorphonuclears. The smallest count in the prodromal stage was 34 cells per c.mm. and the largest no less than 1980. Within a week of the onset of paralysis the count diminishes and mononuclears to a large extent replace the others. The globulin at first is slight and increases in inverse proportion to the cells up to the third or fourth week. Apparently the attitude of the lay press in certain quarters, and of the public generally, left much to be desired, as several of the Boston speakers mentioned the "hysteria" that had surrounded the subject, more particularly in regard to schools and "senseless and useless" methods of quarantine. As there is little evidence in favour of the theory of direct transmission by contact, many of the precautions taken were stigmatised as "absurd." Nevertheless, in such affairs it is clearly the duty of the profession to lead the public, and though our knowledge of the epidemiology of the disease is still imperfect, restrictions ought not to be laid down in which the profession does not believe. At the New York Neurological Society the meeting was held in conjunction with the Neurological Section of the New York Academy of Medicine. There was unsparing criticism of the organisation and the methods adopted to cope with the epidemic. Dr. Frederick Tilney said that the epidemic, the third in nine years, found them unprepared. "Quarantine was a travesty, and hospitals were not ready." Among much domestic criticism which scarcely concerns us reference may be allowed to the fact, emphasised by speaker after speaker, of the lack of coöordination and coöperation between the State health authorities and the professing neurologists of the city of New York. The neurologist was apparently ignored. It was stated that the important report of the Committee of the New York Neurological Society on the epidemic of 1907 (reviewed in THE LANCET of July 9th, 1910) seemed to have been forgotten by those who had the official control of affairs. Eventually it was resolved that the Academy of Medicine should be asked to consider the advisability of appointing a poliomyelitis commission, with four subcommittees, to consider ways and means best calculated to meet and combat a future epidemic: first, a committee on communicability and quarantine, comprised of bacteriologists and epidemiologists; second, a committee on the clinical aspect of the disease, consisting of neurologists, paediatricians, and orthopaedists; third, a committee on pathology, consisting of pathologists; and, fourth, a committee on treatment and immunisation, comprising neurologists, orthopaedists, paediatricians, and bacteriologists. Here in England we have not had such overwhelming epidemics as have ravaged other parts of the world, but it behoves us to profit from the trying experiences of others.

# THE LANCET.

LONDON: SATURDAY, MARCH 31, 1917.

## Medicine and State Control.

THE possibility that the profession of medicine may be transformed by various influences and for different reasons into a State service is frequently alluded to in the public press, and the reason of this is obvious. Medical men are required urgently for the Army and Navy, and no less urgently of the civilian population, and it is evident that if the State were the employer the existing supply would be at the absolute disposal of the authorities without further formality. This consummation may be desirable, but it seems to medical men that there is little general comprehension of what a State Medical Service means. So long as the principal rôle of medicine was to deal with full-blown disease, or to remove acquired disabilities, its practice remained largely a personal matter between doctor and patient, the State merely stepping in to insist that the doctor's claims to treat and relieve were based on a certain minimum of training and attainment. With the dawn of preventive medicine, as evidenced by the desire to stem disease at its source and to avoid the occurrence of physical disabilities, the concern of the State in the matter became intimate, for legislation was required to bring these desirable things about. Thus one Government department after another assumed the control of branches of medical practice in which they were specially interested and appointed special staffs to advise the department on medical matters. The evolution of a medical service to a high degree of importance and efficiency is apparent, of course, in connexion with the Army, where within a generation a sanitary organisation has been created under which typhoid has disappeared from the forces waging the greatest war the world has ever known. But let us not forget that even now the anomaly persists of the Director of the Medical Services having no seat on the War Council and being subordinate to the Adjutant's department. Civilian medical practice is similarly not represented directly in the government of the country, and has not a Minister responsible to Parliament and backed by the support of the people. If the Bill, whose introduction is expected by Lord RHONDDA, the President of the Local Government Board, recognises this point of view, it will assuredly command full medical support.

A unification of the medical services of the country would be the immediate outcome of the appointment of such a Minister. For a long time past the Local Government Board, the Board of Education, the Home Office, and the Board of Trade have had their own medical departments. The National Insurance Commissioners have more recently become largely

responsible for certain uniform medical treatment throughout the country, and here some order exists in the employment of research workers, pathologists, chemists, and bacteriologists in systematic action for the prevention as well as for the detection of disease—we refer to the Medical Research Committee. Elsewhere no such order can be found. During the war the medical services of the Navy and Army have developed enormous activity; the Ministry of Munitions has come in with a far-reaching scheme of industrial hygiene; the Pensions Ministry is dealing with the colossal problem of the disabled soldier, and the Ministry of Labour is now joining it in this work. Perhaps the Minister of Blockade is the only member of the Government who has no medical staff. This divided control means not only confusion and dissipated energy from overlapping, but inevitably leaves places which are no-man's-land. Although the infant is now the object of assiduous care of a Government department, the child of 2 to 5 years has abundant opportunity to develop disease and disability, which is often too advanced for simple and efficient treatment when observed by officers of another medical department. The persistence of that terrible plague ophthalmia neonatorum may, as the recent report of the Central Council for District Nursing in London indicates, be largely attributed to dual notification and control. The general practitioner who attends his patient throughout the seven ages of man is under the observation of as many Government departments in doing so. A Ministry of Public Health, whose rôle it should be to care for the health of the citizen "from the cradle to the grave," as Mr. LONG expressed it, would tend towards efficiency and economy, and initiate a new era in the history of public health. Lord RHONDDA stated recently, when receiving a deputation from the British Medical Association, that he was for such a health department with an advisory medical council to assist it, without repeating Mr. Long's claim that the head of the Local Government Board was himself really the Minister responsible for public health.

All agree that due recognition of the importance of medical science to the nation is desirable, and those who have thought the affair out hold that the unification of central medical control must, to this very end, be worked for. Opinion varies widely on the best method of delegating the central authority. To the official mind a civilian State Medical Service with fixed salaries and orderly gradation from higher to lower authority is the natural solution. The official view is apparently proved by recent experience of the efficiency of the Army Medical Service. But there are many—discipline prevents accurate knowledge of how many—who chafe under the official régime, feeling that their powers are not being used to the best advantage therein. And it must not be forgotten that an overwhelming proportion of the present Army Medical Corps is made up of drafted-in civilians, who have been free to shape their own careers, and who are not at all convinced that the prescribed pattern is very good. And the nation does not like the official attitude

towards its ills. Dr. ESTHER CARLING, chief medical officer of the Berks and Bucks Joint Sanatorium, has told us that town councils cannot deal sympathetically with infant welfare work; and half a century of conscientious practice by Poor-law doctors has not removed the popular prejudice against the Poor-law infirmary. The general practitioner continues to absorb the main esteem of the public, and Sir T. CLIFFORD ALLBUTT's fear of taking out of the general practitioner's hands the responsibility for treatment of many kinds is widely felt in the medical profession. But it would be met by Mr. H. B. BRACKENBURY's offer to Lord RHONDDA to elaborate a scheme for utilising the general practitioner in a unified Health Department. The President of the Local Government Board, in welcoming this suggestion, has stated that his legislative plans are adoptive and present no obstacle to its realisation.

### The Prevalence and Treatment of Cerebro-spinal Fever.

COMPULSORY notification of this disease came into force for the whole of the United Kingdom in 1912, so that opportunity has been thereby afforded for study of its prevalence in this country during war-time, as compared with pre-war conditions, although difficulties in connexion with diagnosis render the statistics at present available somewhat unreliable. With this proviso, the following figures were given recently by Lieutenant-Colonel S. MONCKTON COPEMAN, F.R.S., officer in charge of the hygiene department of the Royal Army Medical College, in an address delivered at the Royal Institute of Public Health:—

Year.	Notification of cerebro-spinal fever.	
	Civilian.	Military (excluding cases originating overseas).
1913 ... ...	279	—
1914 ... ...	315	—
1915 ... ...	2566	1146

The weekly numbers of both military and civilian cases notified during 1916 up to August 31st were indicated in a chart published in the Report of the Medical Officer of the Local Government Board for 1915-1916. It could be seen from this chart that a considerable outbreak of the disease occurred in the early part of 1915, its maximum incidence being reached in the week ending March 13th. In the following year the maximum incidence was less in amount and fell later in the year, but Colonel COPEMAN pointed out the possibility that some of this difference was due to the larger number of men over-seas in 1916 than in 1915, although he reminded his audience that by 1916 the military housing conditions had improved, especially as regards ventilation and the prevention of overcrowding, factors from which much good would naturally be expected.

In a recent issue of THE LANCET we referred to the fasciculus of the *Times* "History of the War" dealing with the epidemic of cerebro-spinal fever

in 1915, and we take the opportunity of modifying a sentence in which we appear to reflect upon the accuracy of our contemporary's history. It was a correct statement in the *Times* that the Director-General of the Army Medical Service invited the Medical Research Committee to come to his assistance when preparing a plan of campaign, having regard to the grave menace to the troops in training throughout the British Isles. The plan was drawn up promptly upon the advice of Dr. MERVYN GORDON, already the author of admirable work in connexion with the bacteriology of the disease, and when later Dr. GORDON was gazetted as a major in the Royal Army Medical Corps, the Medical Research Committee provided his whole-time service for the country on full colonel's pay, on the understanding that the appointment was definitely made by the War Office, and that in devising any arrangements he had the official authority of the War Office and would not be acting merely as a scientific worker employed by the Medical Research Committee. No appointment could have been made more suited to the needs of the situation. Dr. GORDON and Colonel HORROCKS, the adviser on sanitation to the Army Council, made immediate inquiries into the outbreak of the disease that had occurred in the Canadian camps, and later Surgeon-Colonel R. J. REECE, who is now in charge of the military statistics on the subject, was associated with the work. Surgeon-Colonel REECE has informed Colonel COPEMAN that when the revised official figures are available there will be found evidence that in each of the years 1915-1916 the rise in military notifications definitely preceded similar increment in the civilian numbers, thus probably indicating spread of the disease from the military to the civilian population, in which extension the Canadian troops appear to have been specially concerned. The precautions taken in view of the possibility of wide extension of the disease, especially in the new armies under training, were sound and far-reaching. Not only were cases isolated as they occurred, but contacts were segregated, and, in each case, bacteriological examination of cultures was obtained by swabbing the naso-pharynx. Those found not to be harbouring the meningococcus could thus be returned to duty with the least possible delay, while the remainder were isolated until positive results were no longer obtained. A central cerebro-spinal laboratory was equipped at the Royal Army Medical College, and no less than 37 district laboratories in the country were started or coopted with their existing staffs. In these circumstances, pointed out by Colonel COPEMAN, it has been found possible to release about 70 per cent. of the contacts within 24 to 48 hours, and the majority of the remainder within two to four days later, whereas in the absence of bacteriological examination it would have been necessary to retain from duty all these men for three weeks, the average period during which the organism has been found to persist in the naso-pharynx.

Determination by Colonel GORDON of the special characteristics of the meningococci from the cerebro-spinal fluid of cases of the disease has shown that

these may be of four specifically distinct types, of which two are most frequently isolated; but, said Colonel COPEMAN, the type may vary at different periods during the same outbreak. These facts will be recognised as having an important bearing on the question of specific treatment, as a serum produced by the use of meningococci of one type will be practically valueless in the event of the outbreak being associated with another type of the organism. In absence of determination of the special type of meningococci, obviously the likelihood of obtaining satisfactory results from specific treatment will lie in the use of a serum polyvalent for all types, and encouraging results have followed the use of such a polyvalent serum produced by the Lister Institute and others, as noted by Surgeon-General H. D. ROLLESTON in his recent report on Cerebro-spinal Fever in the Navy.<sup>1</sup> In the event of the meningococcus being isolated from the throat, as well as from the cerebro-spinal fluid of a case suffering from the disease, it has been found that the type in each instance will be the same. This also holds good for cultures from the naso-pharynx of positive contacts of the case, a fact which has on occasion proved of special service in the tracing of possibly unsuspected carriers.

As there are certainly indications of the existence of the disease at the present season in several localities, it is well to publish in full Colonel COPEMAN's remarks on its spread and the methods of prophylaxis to be adopted. He said:—

As regards the spread of the disease, the trend of opinion is towards considering the healthy carrier as being for the most part responsible. Several observers, however, have found the meningococcus present to the extent of at least 2 per cent. in the naso-pharynx of non-contacts from non-epidemic areas—in other words, from the general population—so that it is obvious that further information is needed as to the precise circumstances under which spreading of the disease takes place.

*Prophylaxis; Treatment of carriers.*—The meningococcus being one of the least resistant of pathogenic bacteria and easily killed by various disinfectant substances in low concentration, the question arose as to the feasibility of destroying it *in situ* in the naso-pharynx by disinfectant solutions, or sprays.

As regards personal prophylaxis, good results have been obtained by *nasal insufflation* of 0·5 to 1 per cent. solution of chloramine, or of 1-5000 permanganate dissolved in normal saline. For prophylactic treatment of large bodies of men, as also for the clearing up of chronic carriers, promising results have been obtained by causing steam to pass through an *inhaling-room*, the air of which is charged with steam and fine droplets of antiseptic solution sprayed by a steam atomiser. The solutions sprayed have been either 1 per cent. zinc sulphate dissolved in normal saline, or in cases of chronic carriers 1 to 2 per cent. of chloramine. The men remain in the inhaling-room for five minutes, during which they inhale vigorously through the nose.

This simple and detailed instruction will be of service to our readers.

<sup>1</sup> THE LANCET, 1917, i., 56.

Major H. MacCormac, R.A.M.C., will read a paper on Skin Diseases under War Conditions in France before the Dermatological Section of the Royal Society of Medicine at the Society's House on Thursday, April 19th, at 5 P.M. A discussion will follow.

## Annotiations.

"*Ne quid nimis.*"

### WORKHOUSES AND FOOD RESTRICTIONS.

Boards of guardians appear to approach the questions raised by Lord Devonport's effort to restrict the consumption of certain staple articles of diet from different points of view. In the notes recording meetings of guardians in a recent issue of the *Local Government Chronicle* occurs an account of a discussion raised at Liverpool upon a revised scale of dietary for the officers of the workhouse. The allowance of meat appears to have been reduced, to what amount is not stated; but "formerly" the weight assigned weekly to each officer was 11½ lb. A member of the select vestry, who called attention to this figure, expressed not unjustifiable surprise at the digestive powers of those who ate so much. No suggestion, however, seems to have been made as to the substitution of any other kind of food to take the place of the mass of meat which would have to be held back if Lord Devonport's scale were to be adopted. At another guardians' meeting, that at Goole, one of the innovations proposed in the dietary consisted in the substitution of rice-pudding for roast beef, potatoes, and bread in the Sunday dinner for inmates. It was decided after some discussion to make the other reductions proposed in the dietary for week-days but to leave the Sunday dinner as before. No mention is made in the report as to any suggestion of difficulty in the obtaining of potatoes, so possibly the workhouse at Goole is self-supporting in this matter, or has otherwise accumulated a stock. It does not appear either to have been suggested that more economical ways of cooking meat than by roasting it, and the adoption of other foods to lessen the consumption of potatoes and bread, would have afforded a *via media* between the normal Sunday meal of peace-time and the somewhat cheerless alternative of rice-pudding. In another union, that of Kingsbridge, the discussion turned mainly upon the bread ration. Two 4 lb. loaves seem to have been the normal allowance for inmates of Kingsbridge workhouse per week, and the master declared that 7 lb. 5 oz. per head would be the least amount that would suffice. The chairman of the board in support of this view stated emphatically that no working man could subsist upon 4 lb. of bread a week, an opinion which, taken by itself, is reasonable enough. In discussing the dietary of a workhouse, however, it might be borne in mind that such an institution differs from a workman's home, and that its inmates are not labourers in full work. The workhouse has a kitchen and cooks who either are, or ought to be, sufficiently trained to be able to prepare palatable and nourishing dishes without exceeding the limit for meat, dishes, moreover, which would not have to be supplemented by an undue consumption of bread. That an increased, and increasing, expenditure upon food has to be faced by guardians is obvious. They have, however, an advantage besides that of kitchens in which food can be prepared upon a large scale. Owing to their being able to buy upon a large scale they can obtain their supplies more cheaply than private individuals, and there can be no reason why inmates of workhouses should con-

sume more bread, meat, and sugar than their fellow men, or why the possibly unwelcome innovations, which all are now introducing into their daily meals, should be excluded from Poor-law institutions.

#### THE NATION'S TOBACCO BILL IN WAR-TIME.

ACCORDING to the honorary statistician of the British Anti-tobacco and Anti-narcotic League the tobacco bill of the nation for the year 1916 has exceeded that of the previous year by £8,650,000, the total expenditure now reaching the figure of £48,630,000. The increase in consumption, however, according to the same return, is out of all proportion to this, for it is 3·8 per cent., as against 21· per cent. expenditure. The increase in consumption, it is interesting to note, since 1911 is 24· per cent., and the increase in expenditure 53· per cent. It may be concluded that the increased expenditure includes the raised cost of tobacco and duty. Considering, therefore, the increased inducements to smoke owing to the war this advance in consumption is not so large as might have been expected, although the total amount consumed and the money expended upon it appear as formidable figures. Well-meaning people are calling attention to these statistics and ask that some steps should be taken to effect a substantial reduction in this bill in the interests both of economy and the nation's health.

#### VESICAL CALCULUS AFTER WOUNDS OF THE BLADDER.

AT a recent meeting of the Académie de Médecine of Paris, M. F. Legueu called attention to the frequency of calculus after wounds of the bladder. Among 32 cases under his observation he found calculus in 10. Its formation has been explained by infection. But all wounds of the bladder are infected, and the infection does not last longer and is not more severe in cases in which calculus forms than in those in which it does not form. M. Legueu noticed that calculus formed only in cases in which the wound of the bladder was accompanied by fracture of the pelvis. He, therefore, concluded that the calculus must be an indirect effect of the fracture. When a foreign body enters the pelvis it almost always breaks bone in its passage. The fracture is doubly complicated—by communication with the exterior and with the bladder. The urine reaches the site of fracture and fragments of bone enter the bladder. M. Legueu has found them implanted in its wall or included in the calculus. When there are no splinters of bone minute particles pass through the fistula, and it is to them, he thinks, that the formation of the calculi is due. Long after the cicatrisation of the external wounds he has found, with the cystoscope or during operation, an osteopathic fistula connecting the bladder with a focus of osteomyelitis. Through this fistula bone powder falls into the bladder, and remains there the more easily as the patient is immobilised on his back for a long time by the fracture. This insoluble powder becomes the nucleus of crystallisation of calculi. All the calculi which he observed were soft, pliable, and white. When broken a small sequestrum was rarely found at the centre; more often nothing was found, for the powder which gave rise to calculi had been reduced to imperceptible particles. As to the treatment, cystotomy for the purpose of detaching the bladder from its point of adhesion to bone and closing the fistula was not successful. The

bladder is torn in the process, and repair, already difficult, is rendered more so and the case is prolonged. In two cases M. Legueu followed this treatment, producing greater evils than those he tried to remedy. In all the other cases he performed lithotomy with good results. The operation is even possible if the calculus contains bony fragments which cannot be broken up. They can be extracted through the instrument. No doubt fresh calculi may form after the operation, but they can be dealt with by the same simple operation until the fistula closes and the formation of calculi ceases.

#### TUBERCULOSIS OF THE TONGUE.

THE frequency of localisation of tuberculous processes in the tongue as evidenced from the reports of necropsies and from clinical experience is somewhat rare, and it is therefore interesting to note five cases of this condition, observed in the Mayo clinic, in Rochester, U.S.A., published recently by Dr. Luigi Durante in *Il Policlinico*.<sup>1</sup> The reason of the relative infrequency of tuberculous lesions of the tongue, an organ so close to the source of infection, is probably due to two factors: the peculiar structure of the lingual mucous membrane being resistant to direct penetration by the bacillus and also the natural resistance which all striated muscle presents to bacillary localisation owing to the marked antibacterial action of glycogen towards all micro-organisms in general and to Koch's bacillus in particular. The age of the majority of cases of this disease is between 20 and 60 years, it is unknown in childhood when tuberculous lesions are frequent and widespread. These facts justify the conclusion that certain causes incidental to this period of life favour the occurrence of lingual tubercle, such as erosions of the mucous membrane produced by pipe-smoking, dental caries, and toxic glossitis, and also explain the relative frequency in the male sex. The beginning of the lesion is always characterised by specific connective-tissue formation in the shape of a tuberculous nodule situated either in the derma of the mucosa or in the lingual parenchyma, and from this origin two distinct clinical types follow, one in which development proceeds at the expense of the lingual derma, having characters approximating to those of cutaneous lupus, and the other where the intramuscular connective tissue is chiefly involved producing granulomata or being gummatus; they may closely simulate neoplasms or tertiary syphilis. Typical tuberculous ulceration has irregular outlines, with sinuous, soft, red edges, a yellowish base covered with easily bleeding granulations, and may occur in any part of the tongue, but has a preference for the edges and tip. The persistence of these two clinical forms, the ulcerative and the nodular, seems to be influenced by the condition and course which the tuberculous infection assumes in other parts of the body—that is to say, those forms which maintain for a long time the nodular type accompany a tuberculous infection, usually in the lungs, of slow course and without tendency to break down, or else are strictly primary, while those forms which tend to become rapidly caseous are habitually concomitant with and secondary to deep and destructive lesions in other organs. In the 5 cases now published by Dr. Durante 2 occurred in females and all between the ages of

<sup>1</sup> Surgical Section, Oct. 16th, 1916.

20 and 50 years. As no necropsies were made the diagnosis of primary lingual tuberculosis arrived at in 2 cases in the absence of any other apparent tuberculous lesion has only a clinical and not an absolute value. In the other 3 cases it was secondary to, and a late episode of, broncho-pulmonary lesions. In 4 cases the type of lingual lesion was ulcerative, situated at the edge, and the result of a granuloma deep in the parenchyma. In the other case the type was nodular and had remained in that condition for 10 years, and was the only tuberculous lesion ascertained to exist. In the remaining 4 cases the ulcerating stage was developed after three to four months. This shows that it is not so much the local site which determines the different anatomical aspect of a specific process, such as the tuberculous, as the conditions of reaction in the whole organism. There was glandular enlargement in the four ulcerative cases, but not in that where the intra-lingual granuloma remained intact. Clinical diagnosis was easy in three cases in which the ulcer in the tongue existed simultaneously with tuberculous pulmonary lesions. In all cases the nature of the lesion was proved, in two of them by excision and in the others by biopsies previous to treatment by cauterisation.

#### NURSERY SCHOOLS.

TEMPTED by the prospect of high wages, often in addition to the husband's earnings or a separation allowance, a large number of married women are now working in munition factories for periods of 8 to 12 hours on day or night shift. What time the mother has at home and does not spend in sleep she requires for rest and meals, leaving little or no opportunity for attention to the children. To these factors Dr. Sidney C. Lawrence, in his recent report to the Edmonton education committee, attributes the increased infantile death- and sickness-rate, as well as a return to the highly verminous condition of the children first revealed in 1908 by school medical inspection. In order to remedy this situation Dr. Lawrence proposes, not to prohibit married women leaving their homes without making proper provision for the children, but to accept the evil necessity and mitigate its drawbacks by providing for the children elsewhere. He prescribes the raising of the age of school admission to 7 years and the conversion of infant departments into voluntary nursery schools for the reception and maintenance of children from 1 month to 7 years of age, open day and night alike. In each such department he would retain the head-mistress as superintendent with the assistance of suitable "motherly" widows requiring a smaller wage than the school teachers, and he would invite older girls to attend for practical lessons in mother-craft. The expense, he says, of such a venture need not be great, as the Board of Education and the Ministry of Munitions are ready to provide 75 per cent. of the capital cost and a handsome subsidy towards current expenses—up to 7d. a child for 12 hours' attendance. A similar payment by the mothers would leave but a small remaining margin of expense for the local authority to defray. Dr. Lawrence's scheme has, we believe, attracted a good deal of attention and has not escaped criticism in details. On the desirability of providing some sort of other care for children whose mothers go out to work no diversity of opinion can exist, but the risk from infection incurred by segregating

numbers of young children together must not be lost sight of. Whooping-cough and chicken-pox are not at the age of 1 to 5 years the trifling ailments they are often supposed to be, and we now know that measles at that age is a very malignant disorder. Following one upon the other the risk to life is very great, and the larger the nursery school and the less skilled the supervision the greater the risk of catching these complaints.

#### SMALL-POX IN GERMANY.

SINCE the beginning of the year cases of small-pox have occurred in most of the administrative districts of Northern Germany, spread, it is stated, by tramps and wandering labourers. In February a small outbreak was reported in Berlin, leading to the compulsory notification of suspects and a strong recommendation for the revaccination of the civilian population. The *Deutsche medizinische Wochenschrift* of March 1st reports the number of cases in Berlin hospitals on that date as about 50, stating that they mostly arose amongst immigrants or occupants of lodging-houses, and suggesting the advisability of revaccinating adults above 40 years of age in view of Gins's statistical proof (*D. m. W.*, 1916, No. 38) that the immunity of the second vaccination at 12 years of age does not generally survive beyond the forty-fifth year. Practically all the cases were above this age. For a time revaccination in Berlin proceeded so briskly that lymph ran short.

#### THE ESTIMATION OF THE URIC ACID OF THE BLOOD IN BRIGHT'S DISEASE.

IN many clinical investigations the use of a colour scale provides a ready method of exact estimation of quantity in regard to substances of uncertain chemical composition or which do not lend themselves to isolation and weighing. Dr. Paul Bartholow, assistant in applied therapeutics at the College of Physicians and Surgeons of Columbia University, has made an ingenious application of the method to the Brugsch-Kristeller test, which he considers to be the finest so far devised by chemists for the estimation of uric acid, depending as it does upon the rule that the reaction of uric acid and sodium tungstate in solution is marked by a blue colour. He describes the test itself as follows:

One c.c. of blood is sufficient, but it is generally convenient to draw 2 c.c. into a test-tube. When the serum is clear 0·1 c.c. is pipetted into another test-tube, and 2 c.c. of a 7·5 per cent. solution of sodium carbonate is added. To this 0·4 c.c. of a solution of sodium phospho-tungstate is added, and a blue colour, varying in degree according to the uric acid in the serum, spreads beautifully throughout the liquid. The solution of sodium phospho-tungstate is made as follows: 100 grammes of sodium tungstate are dissolved in 80 c.c. of 85 per cent. phosphoric acid and 700 c.c. of water; the whole is boiled several hours and diluted to 1 litre. In using this test in Bright's disease the best method is to compare the colour of the reaction with a colour scale. By running through a large series of reactions with normal serum and serum of Bright's disease, I have made a colour scale, increasing in intensity from 10 to 100. To give examples of its use: two cases of nephritis with retention gave values corresponding to 70 and 80 on the scale. A colour corresponding to 80 and 90 is characteristic of nephritis, parenchymatous and interstitial. Experience will accurately class those cases which give the deepest colour. It is not easy to determine the corresponding quantity of uric acid. If we add the test solution to a standard solution of uric acid and lithium carbonate we find, however, that the colour produced by 5 c.c. of this solution corresponds to 1 milligramme of uric acid in 100 c.c.

Dr. Bartholow recognises that there are possible fallacies inherent to the test. If the serum con-

tains any haemolytic products the reaction must be rejected. Too much serum must not be used, and the sodium carbonate solution should be added to the serum, not *vice versa*. It is possible also, he thinks, that solutions of sodium phospho-tungstate may produce the blue colour with other as yet unknown substances. His own experience, however, of the test, which is a large one, disposes him to think that much may be hoped from it, and that it may be a means of throwing fresh light on some dark corners of Bright's disease.

#### TÆNIA NANA IN HOLLAND.

IN Holland, as in many other European countries, the infection of human beings with tapeworms is not rare. The tapeworm most often met with is *Tænia saginata*, a parasite half an inch wide and 30 feet or more in length, the intermediate host of which is the ox. Dr. C. L. de Jongh has recently described<sup>1</sup> a case of infection with *Tænia nana*, better called *Hymenolepis nana*, which is the smallest of the tapeworms found in human beings, and measures only about half an inch in length and a fiftieth of an inch in breadth. So small a parasite as this is no doubt often overlooked, and this may explain the rarity of its recorded discovery; thus in 1910 only four examples had been noted in Germany, one in England, and none in France, although an endemic infection of the Liége coal-workers in Belgium with it had been described by Malvoz in that year. Dr. de Jongh's patient was a little girl at The Hague, aged 2, sent to the hospital with wasting and diarrhoea. The diagnosis of gastro-enteritis was made, but the ova of *H. nana* were found in the stools in great numbers. Treatment with santonin was unsuccessful; the exhibition of 250 of the seeds of *Cucurbita pepo* followed by castor-oil gave a satisfactory result, and the child made a good recovery. Dr. de Jongh discusses the few facts that are known with regard to the life-history of this intestinal parasite, and concludes that it is not identical with the *Tænia murina* so often found in rats and mice. It is not known what animal serves as intermediate host to *H. nana*, but possibly the human host serves as the intermediate host as well. Investigating the stools of the other members of the patient's family, Dr. de Jongh found ova of this tapeworm in the excreta of the father and two other children, but not in those of the mother and the youngest child; these three carriers of *H. nana* all had a tendency to diarrhoea, but the mother and youngest child had not. Treatment with the seeds of *Cucurbita pepo* relieved the two children of over a hundred of the tapeworms each. Dr. de Jongh is not able to explain how these four members of this family came to be infected with this tapeworm; they had lived in the same house for five years, and none had been out of the country except the father, who had ten years previously lived in Duisburg for a few months.

Queen Alexandra has appointed Mr. Hugh Mallinson Rigby, F.R.C.S., surgeon to Her Majesty's Household.

THE late Lady Grenfell has bequeathed £1000 to the Hospital for Sick Children, Great Ormond-street.

#### MEMORANDUM UPON SURGICAL SHOCK AND SOME ALLIED CONDITIONS.

THE phenomenon of oligæmia—or reduction of the volume of the blood in effective circulation—has figured prominently in the theories of surgical and traumatic shock (due, in the main, to American investigators) which have been current during recent years. There is no need to emphasise the importance at the present time of this condition, or that of the acute circulatory failure, similar to this in so many respects, which characterises some of the graver forms of infection and toxæmia. Information has reached the Medical Research Committee concerning some separate experimental inquiries into these conditions which are at present in progress on behalf of the Committee, and which promise to throw light on the production, by causes which have so little immediately obvious connexion with one another, of these groups of symptoms having so many points in common.

It appears to the Committee most desirable that clinical observations, bearing on the importance of the different suggested factors in the genesis of shock and allied conditions, should proceed concurrently with the further experimental investigations. They have, therefore, with the consent and aid of the investigators concerned—to whom they are greatly indebted—prepared the following preliminary notes for circulation among those having opportunity for clinical observation, and they have ventured to add some suggestions for the practical application of the results already gained, which seem to them worthy of attention and trial.

1. H. H. Dale and P. P. Laidlaw, whose primary object was a closer analysis of the shock-like phenomena produced by injection of various protein and bacterial poisons, of the sensitising antigen into an anaphylactic animal, &c., resumed, in the first instance, their examination of the action of the base  $\beta$  iminazolethylamine ("histamine"), the shock-like action of which they described some years ago. Taking readings of the haemoglobin value of the arterial blood with Haldane's haemoglobinometer, or of the percentage volume of corpuscles in the blood with a hematocrit, they find that the profound fall of blood pressure produced by this substance is accompanied by a striking concentration of the blood, amounting in some cases to a loss of one-half the original volume of plasma in about five minutes. The liver appears to be the organ most actively concerned in this reduction of the plasma-volume; but it is not exclusively responsible, for the phenomenon occurs, though less regularly, when the drug is injected after exclusion of all the abdominal viscera. The concentration is apparently effected not merely by loss of water and diffusible constituents, but by the passage into the tissues and lymph-spaces of all the plasma constituents, since the protein content of the plasma does not rise in proportion to the reduction of volume.

If an animal, moribund from this type of shock, is opened, it is found that the heart is executing muscular beats of moderate vigour, although the arteries are pulseless. The veins are not distended and the great veins fill only very slowly from the periphery if clamped. A large part of the blood, in fact, has disappeared from effective circulation, and the weakness of the heart-beat is due to defective inflow from the veins.

The condition cannot wholly be explained by the loss of plasma-volume above described, for Dale and Laidlaw have several cases on record in which the drug produced a "shock" of some severity, with the general signs of oligæmia as above described, but with no loss of plasma, as measured by concentration of corpuscles, or a loss so small as to be quite inadequate to explain the effect. They further regard a loss of tone of the smaller arteries as insufficient to account for the extreme circulatory depression (the still incomplete evidence points rather to these being constricted in these circumstances), and provisionally attribute the shock in the first instance to a widening of the whole capillary area in the viscera and the musculature. The active contractility of the capillaries has been frequently described, and important evidence of its existence in man has just been provided by Cotton, Slade, and Lewis (Heart, 1917). Dale and Laidlaw suppose that, under the action of the poison, the capillary tone is lost, so that, the blood from the arterioles being diffused and stagnant among the slack capillary channels, the quantity of blood reaching the veins is inadequate for the filling of the heart. The cardiac output falls in consequence to a very low level.

<sup>1</sup> Nederl. Tijdschr. v. Geneeskunde, Amsterdam, 1917, I., 541.

An attempt will be made to test by direct experiment this hypothesis of circulatory stagnation as the result of general loss of tone of the capillaries. About the main fact—that there is a depletion of the macroscopic vessels both on the arterial and venous sides—there can be no room for doubt; and it will be obvious how this deficiency of blood-volume, relative to the total capacity of the system, will be aggravated by the direct reduction of the blood volume, owing to loss of plasma into the tissue spaces which usually accompanies it. The already sluggish circulation will be further impeded by the increase of the viscosity of the blood, mainly due to the increase in the proportion of corpuscles to plasma. This change of viscosity has been directly observed by Trevan (*vide infra*). The slowness of the capillary circulation, again, through the muscles and other tissues needing a plentiful supply of oxygen, will lead to defective oxidation, with resulting acidity, and so to a further tendency for passage of water by osmosis from the blood, as suggested by Henderson. Lastly, the fall of arterial pressure, owing to defective filling of the chambers of the heart, and the increased viscosity of the blood, will so reduce the rate of the coronary circulation as eventually to interfere with the nutrition and oxygenation of the heart muscle itself. It will be seen, therefore, that when once the described condition is established a series of "vicious circles" is set up.

The determination of the change of plasma-volume from haemoglobinometer readings may be illustrated by an example. From a cat (under ether) an initial sample of arterial blood gave a haemoglobinometer reading of 80 per cent. When the profound shock produced by intravenous injection of 10 milligrammes of the biphosphate of histamine (about 3 milligrammes of the base) had fully developed—i.e., about seven minutes after the injection—a second arterial sample gave a haemoglobinometer reading of 120 per cent. In order to translate these values into relative volumes of corpuscles and plasma, we must know the initial ratio of these volumes, and assume a constancy of haemoglobin content in the corpuscles. The hematocrit showed that the corpuscles originally occupied one-third, and the plasma two-thirds, of the blood-volume, which is a normal ratio for a cat. The rise of the haemoglobinometer reading from 80 to 120 per cent. must be taken to indicate an increase in the proportional volume of corpuscles in the same ratio. So that the percentage of corpuscles has risen from  $33\frac{1}{3} \times \frac{120}{80} = 50$ . If the volume of corpuscles has remained constant this change of proportion indicates a fall of plasma-volume from 66·6 to 50 per cent. In other words, the plasma, which originally occupied twice as great a volume as the corpuscles, now occupies a volume equal to that of the corpuscles, so that one-half of the plasma has disappeared from the circulation. A hematocrit determination on the second sample actually showed the corpuscles and plasma occupying equal volumes, so that the assumption of a practically constant haemoglobin content in the corpuscles was justified. The only means, other than the loss of one-half of the plasma, by which such a change could be effected would be a doubling of the number of red corpuscles in circulation, and it does not seem credible that this could occur in the course of a few minutes. It should be noted, further, that the arterial blood, on which the readings were made, represents a mixture of all the blood reaching the heart from the different organs. Blood taken from the portal vein when the shock-like condition has been produced shows an even greater concentration than that from the arteries, and even this portal blood contains an undue proportion of blood from those of the capillaries in the splanchnic area in which the circulation is still relatively effective. It must be supposed that in many the vanishing arterial pressure is no longer able to maintain a circulation, so that the blood in them is stationary and its concentration extreme.

Being impressed with the similarity of such a condition to surgical "shock," Dale and Laidlaw have made a short series of attempts to produce such a shock in anaesthetised cats by prolonged manipulation of the abdominal viscera, which, as Mann and others have pointed out, is the only method by which a traumatic shock can be produced in *Carnivora*. In two cases profound shock, with no tendency to spontaneous recovery, was obtained, and in both these such a rise of haemoglobin value was observed, concurrently with the onset of the shock, as to indicate a serious depletion of the plasma-volume. In others a less profound shock was obtained, with a tendency to spontaneous recovery when the abdominal wound was closed and the animal left to itself under the anaesthetic; in these no significant change in the haemoglobin value was observed. In these cases also the manipulated bowels became conspicuously reddened and ultimately blueish in appearance, but the blood pressure could be temporarily driven almost to its original high level by compressing the whole mass of intestinal coils, and so driving the blood out of their capillaries into the general circulation. In these cases, therefore, such shock as was obtained seemed to be due purely to stasis in the abdominal capillaries, as previously described by Mann.

Meanwhile, Captain Marshall, R.A.M.C., had commenced a series of observations in France on the haemoglobin content of the blood in the different classes of case met with in a casualty clearing station. The Committee understand that among Captain Marshall's observations are some on shock, which support the view that loss of plasma into the tissues is an important factor in the condition.

2.  $\beta$ -Iminazolylethylamine (histamine) was chosen by Dale and Laidlaw for this investigation as a pure substance, producing effects of the kind under investigation in exact dosage. Effects of the same general type are produced by many products of protein digestion, bacterial products, &c. Among such effects those due to the so-called toxæmia of gas gangrene are of special importance at present. The resemblance between the symptoms of this condition and those of surgical shock or of a severe hemorrhage has frequently been described.

An investigation is now being carried out by H. H. Dale and J. McIntosh into the symptoms presented by animals dying after a local infection of the limb muscles by organisms of the gas gangrene group isolated from material obtained from fatal human cases. The onset of a fatal shock-like condition in such experiments has again been found to be associated with a progressive rise in the corpuscular content of the blood pointing to a steady loss of plasma. It may be pointed out that such an effect was perhaps to be expected. The capillaries in the tissues surrounding the infected muscle are so affected that an enormous local outpouring of plasma occurs. Whether the general symptoms are due to passage of the infecting organisms into the general circulation or to the absorption through the lymph channels of toxic products of the local breakdown of muscle, effects on the general vascular endothelium of a similar kind, though much less in degree than those produced by the concentrated local action, might be expected. A general loss of capillary tone and a morbid increase of permeability of capillary walls might therefore be expected to result from absorption into the general circulation of the fluids from the infected area. The evidence as yet available confirms this expectation, and suggests that there is a fundamental similarity of origin, underlying the similarity of symptoms, between the toxæmia of gas gangrene and other shock-like conditions. It must be remembered, however, that failure of the heart from any cause will be attended by some degree of blood concentration if the process is sufficiently gradual. More work is needed before the significance of the phenomenon in these cases can be estimated with confidence.

3. Concurrently with the foregoing investigations, F. A. Bainbridge and J. W. Trevan have been conducting an investigation into the genesis of shock by other means, and the same factor of concentration of the blood has presented itself in their observations. Their experiments hitherto have been mainly concerned with the effects on the portal and systemic venous pressures and on the general distribution of blood in the circulation, produced by repeated injections or by long-continued, slow infusion of adrenalin. The inquiry was suggested by the fact, demonstrated by Elliott, Cannon, and others, that extreme emotion or severe pain, which are factors in some cases of shock, are accompanied by an outpouring of adrenalin from the suprarenal glands. Bainbridge and Trevan have injected adrenalin slowly into a systemic vein in anaesthetised dogs for 20 minutes or longer, at a rate sufficient to maintain the arterial pressure at a supranormal level comparable with that attained during moderate stimulation of a sensory nerve. During the injection the portal pressure rose to, and remained at, a high level, while the systemic venous pressure was not significantly altered or even fell slightly. Meanwhile readings with the haemoglobinometer and the hematocrit showed a steady decrease in the volume of the blood-plasma relatively to that of the corpuscles. In one case the haemoglobin value rose from an initial 95 per cent. to 129 per cent. Such a relative increase of corpuscular content would involve a large increase in the viscosity of the whole blood; an actual determination showed an increase of viscosity in the proportion of 6·8 to 9·1.

When the injection of adrenalin was stopped, the arterial pressure rapidly fell to a low level while the portal pressure remained high, and the animal passed into a condition of shock, with feeble pulse and shallow respiration. The relation of the portal and systemic venous pressures indicated an obstruction of some kind to the flow of blood through the liver. This was made further evident, in the later stages of the effect, by the striking turgidity of the liver itself. If the flow of lymph from the thoracic duct was recorded, it was observed to undergo a striking acceleration, as the obstruction in the liver developed in consequence of the infusion of adrenalin. The nature of this obstruction is not yet clear, and will be the subject of further investigation. Its effect, especially after the cessation of the inflow of adrenalin has allowed a dilatation of the splanchnic arterioles, is a collection of a large part of the blood in the congested splanchnic area. When to this is added the

steady loss of fluid from the blood by exudation into the tissues, it will be seen that the final result, as regards the activity of the heart and the general circulation, will be closely similar to that described above in connexion with Dale and Laidlaw's experiments. The failure of the output of the heart from defective venous inflow, due to reduction of the volume of blood in effective circulation, leads to a profound collapse of the arterial pressure; the loss of plasma into the tissues not only aggravates this defect of volume, but, by increasing the viscosity of the blood, further retards such flow through the capillaries as the low arterial pressure could otherwise maintain; and this retardation yet further checks the venous inflow to the heart. The blood travels very slowly round the body under such conditions, and the supply of oxygen to all the tissues becomes inadequate. This inadequacy is accentuated by defective oxygenation of the arterial blood, which remains dusky in colour even with artificial respiration.

#### 4. Some Practical Suggestions and Inquiries.

(A) The point of most novel interest emerging from the above notes is the importance which the different sets of workers attribute to loss of plasma into the tissue spaces, as a factor in the production of the circulatory failure. The presence of such a factor was suggested by Henderson, Mann, and others, but its extent and significance have hitherto been rather vaguely indicated. Such loss of fluid from the blood, causing both deficient volume and excessive viscosity, has for some time been clinically recognised as an essential factor in the collapse occurring in conditions like those of cholera and bacillary dysentery, in which the fluid is lost through more obvious channels.

It is here suggested that clinical observation on changes in plasma-volume in traumatic shock, post-operative shock, and the toxæmia of gas gangrene may yield valuable information. The only instruments clinically applicable to the detection of such changes are the haemoglobinometer and the haematocrit. It will be evident that the interpretation of such observations will be a more complicated matter than that of results obtained under the controlled conditions of experiment; for an estimate of the plasma-volume by these methods depends on the assumption that the volume and haemoglobin content of the red corpuscles remains constant. It cannot, for example, be expected that a loss of plasma occurring in shock consequent on an extensive wound, with much haemorrhage, will be accompanied by an absolutely high haemoglobin-value or haematocrit reading. Again, in a protracted case of toxæmia from gas gangrene, the observation will be vitiated by the probability that, though plasma may be draining from the vessels into the tissue spaces, a coincident destruction of red corpuscles is taking place. It is hoped, however, that a careful selection of suitable cases for observation, and attention rather to change of the corpuscular content, as shown in a series of observations at short intervals, than to the absolute initial value, will enable information to be obtained as to the significance of this factor. It may be suggested that cases of traumatic shock without serious haemorrhage, of post-operative shock, of intestinal obstruction, of extensive burning, of anaphylactic shock, and of the rapid, fulminating type of toxæmia from gas gangrene, are likely to give relatively uncomplicated data for this purpose.

(B) The experimental results suggest that the removal of blood from effective circulation may be brought about in more than one way. It would be of interest to know whether different types of shock can be clinically recognised; in particular, whether a type with circulatory obstruction in the liver, as shown by swelling of this organ and congestion of the portal vein and its tributaries, can be differentiated from a type without this feature; and, if so, whether the nature of the primary cause of the shock has any relation to the type produced.

(C) Prevention.—If shock is, indeed, due to oligæmia, its many points of similarity to the collapse produced by a dangerous haemorrhage need no explanation. It will further be obvious that an antecedent haemorrhage, insufficient in itself to produce collapse, may be an important factor in the subsequent onset of shock, in so far as this condition is due to defective volume, apart from increased viscosity of the blood. The normal reaction to a simple haemorrhage, of sufficient severity to diminish the output of the heart and lower the blood pressure, consists in the abstraction of fluid from the tissues until the volume of the blood is again adequate to maintain the cardiac output. Dale and Laidlaw find that a similar dilution of the blood normally accompanies, and tends to correct, a fall of pressure due to arterial dilatation. In shock, according to the indications of the experiments already described, this restorative reaction fails completely and fluid continues to pass from the blood, though the arterial pressure has fallen to a very low level. It will be evident, therefore, that when shock is already imminent a relatively small haemorrhage may have a serious influence in determining its onset. Any other causes tending to diminish the blood volume, such as fatigue, exposure, or prolonged abstinence from food and

water, may be expected to predispose to shock for a like reason. Mention should be made also of the possibility that measures preparatory to an operation in hospital, if they include free saline purgation and severe abstinence from food and water, may contribute to the danger. Cases for urgent operation must constantly present themselves to the military surgeon, in which the antecedent conditions are those mentioned above as tending to depletion of the blood volume, and therefore predisposing to shock. A free supply of fluid, by infusion of physiological saline into the rectum or the subcutaneous tissues, as already used by many surgeons, may be expected to have a special preventive value in such cases. The indications, however, are that such measures, to have any value, must be begun before or early in the operation. When once the condition of shock has been developed, physiological saline, or Ringer's solution, even if injected intravenously in large volume, appears to have a very limited and temporary value; for the diluted plasma passes with increased rapidity through the slack and permeable walls of the capillaries, and the fluid leaves the circulation almost as quickly as it is run in.

(D) Treatment.—Unfortunately, little can be said as yet as to the treatment of shock and allied conditions when once developed. Suggestions only can be made of measures which may be tested with possible advantage and without danger. It is hoped that further experiment may warrant more positive recommendations at a later stage. Pituitary extract causes a prolonged and general contraction of the arterioles, and thereby diminishes the total capacity of the circulatory system and mitigates the effect of deficient blood-volume. The tendency of adrenalin to produce obstruction to the circulation through the liver, as described above, makes it probable that the use of this substance would, in some cases, eventually aggravate the condition which it was designed to cure; its action is, in any case, so fugitive as to be of little value. The action of pituitary extract is free from both these drawbacks; its value in some cases is already well recognised, and, with the ordinary measures for restoring and conserving the body temperature, needs no further mention.

The failure of injections of physiological saline in fully developed shock has already been mentioned. Experiments already made seem to indicate that better results might be obtained by the use of intravenous injections of hypertonic saline, the value of which in the treatment of cholera and bacillary dysentery is already familiar. Whether the action of these is entirely due to the passage of water into the vessels by osmosis, or in part to a restorative effect of the hypertonic solution on capillary tone, is not clear. In this connexion it may be recalled that calcium ions have been found to have a specific action in reducing abnormal permeability of capillaries (*cf.* Wright; also several papers from the Vienna school). It seems reasonable, therefore, to suggest that a fluid representing a concentrated Ringer solution should be used rather than one in which only the proportion of sodium chloride is increased. The following formula might be tried—

Sodium chloride	...	...	...	2 grammes.
Potassium chloride	...	...	...	0.05 "
Calcium chloride	...	...	...	0.05 "
Water	...	...	...	100 c.c.

and the value of increasing the relative calcium content beyond this proportion might cautiously be tested.

The deficient oxidation occurring in any condition of circulatory failure will lead to an abnormal acidity of the tissues, and thereby tend to raise the concentration and viscosity of the blood in the capillaries. Administration of alkalies should, therefore, help to relieve the condition, and injections of sodium bicarbonate, as recommended by Wright for the treatment of gas gangrene, should form a valuable addition to large injections of a hypertonic saline mixture. The limited solubility of calcium bicarbonate makes it advisable to give the bicarbonate solution as a separate injection. Hogan and Fischer recommend the following formula for an alkaline hypertonic saline:

Sodium chloride	...	...	...	28 grammes.
Sodium carbonate (crystalline)	...	...	20	"
Distilled water	...	...	...	2 litres.

Bayliss recently drew attention to the importance of the factor of viscosity in solutions used to replace blood lost by haemorrhage. He considered that gum acacia was a suitable substance to add to saline for such purposes, as imparting the requisite viscosity and as being a colloid with a definite osmotic pressure. Hogan and Fischer, on different theoretical grounds, have recommended the addition of 2 per cent. of gelatin to a saline solution for intravenous infusion. It will be evident, from what has been said above, that the aim in treating shock should be restore the volume of blood in effective circulation, and at the same time to reduce the abnormal viscosity. While, therefore, a small addition of gum to the saline fluid used for injection may be valuable, the proportion of 7 per cent., suggested by Bayliss, as

bringing the viscosity of the saline up to that of normal blood, would be unduly high. An addition of 2 or 3 per cent. of gum acacia to the saline solution above suggested might be tried; but it will be possible to make more definite recommendations when there has been time for experiment with solutions of different formulæ.

The defective oxygenation of even the arterial blood, in experimental shock as above described, suggests that inhalations of oxygen may have some value in these conditions.

The Medical Research Committee, whose address is 15, Buckingham-street, Strand, W.C. 2, will receive gratefully any reports upon clinical studies or experimental observations which may be sent to them as bearing upon the questions raised in this Memorandum. They hope it may be possible later to issue a further Memorandum, or series of reports, in which further results of the inquiries now in progress may be given, together with such relevant clinical observations as may then be available.

### PUBLIC DENTAL SERVICE.

THE particulars follow of certain dental clinics which have been established in various centres to provide proper dental treatment for adult patients whose incomes are below £160 per annum. It has not yet been found possible to arrange for dental benefits under the National Insurance Act, and as (in the present state of the finances of the country and of the Act) such treatment is not likely to be provided under a State-aided scheme, it is important to consider carefully what can be done by voluntary means to meet the needs of this class of patient. The schemes show that where these clinics have been established much good work has been accomplished in various important centres. They have generally been inaugurated and worked by the dental surgeons in the central town, apparently often as an incorporated body under the Companies Acts, so that the financial liability of the members is limited. In most cases it expressly stated that all the dentists in the locality favour the scheme; doubtless, many of the out-patient attendances must be made by the younger practitioners, but it is a matter of great importance that all the practitioners in the area, both medical and dental, should take a friendly interest in the movement. The anesthetics are administered by the local medical practitioners, and they should be represented on the local committees. It is interesting to note that in several districts the dentists consider the £160 income limit too high. In Bournemouth the income limit is fixed at £120 per annum; in Glasgow it is £104; in Nottingham there is a sliding income scale, with a different rate of fees for each class of income.

It is to be hoped that these clinics will not simply serve for the extraction of teeth and for the supply of artificial dentures, but that the preventive side of dentistry will be kept well in view. The excellent work which is begun in so many elementary school dental clinics should be carried on in these clinics for adults, which may also be made most useful centres for the spread of simple instruction in mouth hygiene, while forming an excellent medium for combating unqualified dental practice.

#### DENTAL CLINICS.

The Brighton and District Public Dental Service was founded in 1907 to provide treatment by qualified and registered dentists for persons unable to pay the usual fees, for those entitled to medical benefit under the National Health Insurance Act, and for others with an income not exceeding £160 per annum. The service uses the premises of the Brighton, Hove, and Preston Dental Hospital at 27, Queen's-road, Brighton, a moderate rental being paid to the hospital. There are two well-equipped surgeries, with the necessary waiting-rooms and offices. A member of the staff is in attendance during five evenings in the week. At present 27 dentists are on the list of the active staff, but most of the members of the profession in the district are associated with the service. Patients may select their own dentist, and are seen either by appointment at his house or at the rooms of the service. Fees are payable in advance at the office, but may be remitted in instalments. The takings are distributed quarterly to the members of the staff who have done the work after deduction of a percentage

for administrative expenses. The Service undertakes all the dental treatment provided in the district by the Domestic Servants' Insurance Society for its members. It received grants amounting to £123 for work done for the Soldiers' and Sailors' Dental Aid Fund until the closing of this Fund in January, 1916. Its scale of fees has been adopted by the East Sussex Insurance Committee as the basis of payment for dental treatment on account of sanatorium patients. From year to year there has been a steady, though slow, increase in the number of patients treated by the Service. The slow growth may be attributed to the absence of advertising which naturally places the Service at a disadvantage with the numerous unregistered practitioners who compete at equally low, or even lower, fees.

The present tariff is as follows:—

Ordinary extraction	1s.
ExtraCTION with local anaesthetic	2s. 6d.
Extraction with nitrous oxide gas	5s.
Filling	2s. 6d.
Filling, with root treatment	5s.
Scaling	2s. 6d.
Artificial teeth:	
Upper denture, from	10s. to £2
Lower	10s. to £2

The Reading and District Public Dental Service (Central office, 22-25 Chain-street) is affiliated to the Borough of Reading Medical Society, Limited, and was started in 1912. The Dental Service is an association of all the legally qualified dental practitioners in the borough, and is intended for those who are unable to pay ordinary fees, and who are either (a) subscribers to the Borough of Reading Medical Society; (b) insured persons attended by medical officers of the above society; or (c) persons residing in the neighbourhood of Reading who are subscribers to the Public Medical Service, or insured persons attended by medical officers of that Service. Each patient may select the member of the Service by whom he desires to be attended, but it is open to each member to limit the number of patients whom he will consent to attend, or decline to attend any individual patient. Fees are payable in advance and those for prosthetic treatment can be settled in instalments. The total fees approximate to £1000 per annum. The minimum and maximum fees are as follows:—

Extractions (ordinary)	1s.
Extractions (with anaesthetic)	2s. 6d. to 5s.
Special operations	3s. 6d. to 5s.
Dentures (vulcanite):—	
Large or full upper or lower	£1 10s. to £3 each.
Medium or small upper or lower	10s. to 30s. each.

The Bournemouth and District Dental Clinic, Ltd., was started in 1913 with a centre at "Edgemoor," Old Christchurch-road, Bournemouth, with the object of providing dental treatment, both surgical and mechanical, for patients of limited income. Twenty-two qualified dental surgeons of Bournemouth and district share the attendance at the clinic, of which the hours are 9 A.M. to 7 P.M. and 9-1 on Saturdays. Anesthetics, when required, are administered by medical men. The fees charged vary according to the weekly income of the applicant, and in cases of married people according to the number of children dependent upon them, but no person having a larger income than £120 per annum will be eligible for treatment. After working for a short while in order to gain experience a limited liability company was formed, the shareholders being limited to qualified dental surgeons, and five directors act as a committee of management. Expenses are met out of revenue, and after paying a fixed rate of interest on capital the balance is allotted half-yearly *pro rata* to the members who have done the work.

The Public Dental Service in Glasgow was inaugurated in 1913-14 on the lines of similar public services in the south of England, with the object of placing the highest dental skill and the best material within the reach of the less well to do. The Scottish Dentists' Association, Ltd., was incorporated on April 9th, 1914, under the Companies Act, in order to afford adequate protection to the members of the service. Under the memorandum and articles of association there can be no division of any profits amongst the members. Any surplus profit has to be used for extension of public dental services or kindred objects. The initial funds, amounting to £400, were subscribed by guarantee of members, who now number about 130. The first clinic was established in the Partick district of Glasgow in November, 1913; the second in Crown-street, in

the south-east district of Glasgow, in January, 1914; the third in Hamilton, a town ten miles south of Glasgow, the centre of a large industrial population, in July, 1914. These were fitted out on a common plan, including operating-room, waiting-rooms, and a room for lady attendant. The evening being the most suitable time to get into touch with the class for whom the service is intended, the rooms are open from 5 to 9 P.M. Between 5 and 7 P.M. the attendant receives patients and makes appointments, while from 7 to 9 P.M. the operators are in attendance each day except Sunday. Six dentists undertook to attend at each clinic, and they are supported by an adequate relief staff. It was laid down that the clinics were for the treatment of patients whose income did not exceed £104 per annum, the income standard of £160 under the National Health Insurance Act being held to be too high.

Local medical practitioners in the various areas have supported the clinics and expressed their appreciation of the service. About 2550 patients have been treated up to date, but since the commencement of the war the natural development of the clinics has been checked. Among the patients the alteration of hours of employment and restriction of lighting have conduced to a falling off in attendance, and many of the operators have gone on active service. The Hamilton branch, which was peculiarly affected by economic conditions, has been closed. On the outbreak of war three clinics, with a staff of 60 operators on day duty, were placed at the disposal of the military authorities. Gratuitous service was given in order to render dentally fit many recruits who would otherwise have been rejected, and during four months about 700 men attended for extractions, fillings, and dentures. The smallness of the number of recruits treated was probably due to the fact that the men could not be spared from training and were also frequently on the move. Subsequently, at the request of the Scottish Command, the association undertook to organise as a recognised centre the dental treatment of soldiers in Glasgow and a district including the counties of Lanark, Renfrew, Dumbarton, Ayr, and the town of Falkirk. During one year 6000 soldiers attended. 20,000 extractions, 6000 fillings, and the provision of 1500 dentures was carried out.

The minimum scale of fees was fixed at :—

Extraction without anaesthetic	6d.
" with local "	1s.
" with nitrous oxide "	3s. 6d.
" with other general anaesthetics "	10s. 6d. (Plus anaesthetist's fee.)
Fillings	3s. 6d.
" with root treatment "	1s. 6d.
Scaling	2s. 6d.
Dentures: Partial, per tooth	3s. 6d.
Minimum	7s. 6d.
Full upper or lower	£2 5s.
" with ext.	£2 10s.

The Nottingham Qualified Dentists Public Service was inaugurated in June, 1914, as a result of meetings held by the local branch of the British Dental Association, to which all registered dentists in Nottingham and district were invited. The premises are centrally situated at 2, Stratford-square, Shakespeare-street, Nottingham, and comprise a well-equipped surgery as well as anæsthetic room and the usual offices. There are 5 honorary and 16 active members, the latter attending daily from 9 A.M. to 8 P.M., except on Tuesdays and Fridays, when the Service is closed from 2 to 6 P.M. Dental treatment is provided for persons whose average weekly income does not exceed 50s. Applicants are placed in three classes: A. Those whose income does not exceed 25s. weekly; B. Those with incomes of from 25s. to 35s. weekly; C. Those with incomes of from 35s. to 50s. weekly—the fees varying accordingly, payable in advance and in small instalments if desired. There is free choice of dentist from the list, but no change can be made for the period of one year. Patients are seen at the dentist's private house as well as at the clinic. When war broke out, the organisation of the service was placed at the disposal of the local military authorities, and dental treatment was given free, until a scale of army fees was established, to men who would otherwise have been rejected for the army. The battalions raised by the local Parliamentary Recruiting Committee received dental treatment, more than 3300 patients being treated with 14,000 extractions and 7500 fillings. Up to September, 1916, the number of private patients treated by the service amounted to 365, with 1624 extractions, 206 fillings, and 172 dentures. The Service is now officially recognised as the centre for army dental

treatment in Nottingham, for the wounded in hospital, and for billeted troops. A dental clinic was formed in the summer of 1915 to provide dental treatment at a camp 20 miles from Nottingham. Two dentists from the service attended daily on five days a week. Members have also visited camps in the district to help the military authorities with work urgently needed. The council is at present considering ways and means of bringing the Service to the notice of those persons for whom it was intended. Public dental services, although organised for the benefit of the working classes, at present have no means of gaining publicity other than by recommendation from patient to patient.

The Birmingham Qualified Dentists Public Service was started in 1916 at 9, Great Charles-street, Birmingham, to give dental service to persons whose income does not exceed £160 per annum and who are unable to pay ordinary fees. Any qualified and registered dentist practising in Birmingham and district, if a member of the British Dental Association, is eligible for election as a member of the Service. The number of members is limited to 20. The management of the Service is in the hands of a committee consisting of the members and honorary associates for the time being, with an executive committee made up of the officers and five unofficial members. Any patient entitled to the benefits of the Service may select the member by whom he desires to be attended, but each member may limit the number of patients whom he will attend or decline to treat an individual patient. Minimum fees are fixed, payable in advance or by instalments in the case of prosthetic treatment. These are as follows:—

Ordinary extraction	1s. per tooth.
Local anaesthetic	2s. 6d. and 1s. per tooth after at same visit.
Gas	3s. 6d. and 1s. per tooth afterwards, maximum 10s. 6d.
Scaling	2s. 6d. to 5s. per sitting. Subsequent visits 2s. 6d. per visit.
Fillings, plastics, 2s. 6d., 3s. 6d., 5s. (according to cavity).	
" root fills,	7s. 6d. to 10s. 6d. (including filling).
" porcelain inlays,	7s. 6d. or 10s. 6d. (root filling 2s. 6d. extra).
" gold 10s. 6d. and upwards (root-filling 2s. 6d. extra).	
Crowns from 5s.	
Dentures, £3 10s., £5, and £6, according to style of denture.	
Complete upper or complete lower dentures, £2, £2 10s., and £3.	
Partial dentures, 3s. 6d. to 5s. per tooth, min. 10s. 6d.	

## THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

### SUBSCRIPTIONS.

The following additional subscriptions to the Fund have been received:—

	£ s. d.
Sale of ladies' jewellery (per Dr. Colquhoun, Dunedin, N.Z.)	5 0 0
Dr. W. W. David	2 0 0
" La Tricalcine"	8 19 8
Mr. J. Y. W. Macalister	5 0 0
Dr. G. D. H. Carpenter (23rd donation—total, £23)	1 0 0

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund crossed Lloyds Bank, Limited.

### THE APPEAL FOR SURGICAL INSTRUMENTS.

Surgical instruments should be sent to the Master of the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C.

**THE CAMPAIGN AGAINST VENEREAL DISEASES IN BELFAST.**—A Belfast correspondent writes: "The educational subcommittee of the Belfast branch of the National Council for Combating Venereal Diseases have arranged for courses of lectures to be given to teachers—men and women being separately addressed—social workers, and nurses, while a conference of the clergy to consider the question in its moral aspects has also taken place. All these plans are in line with the recommendations of the Royal Commission on Venereal Diseases, but thoughtful people are asking the question, Has education of the public ever yet stopped any epidemic? and the reason for such a reflection is that such a method only reaches those already convinced. The real enemy is never unmasked in this way, and until we adopt in civil practice what has already been done in the Army, both at home and abroad, actually *since this war broke out*—namely, notification, compulsory isolation, and treatment—it is hopeless to expect any real progress. It is unfortunately the case that audiences destitute of any medical training, after listening to lectures on venereal diseases, often take up entirely erroneous ideas, and in the end little real permanent good is accomplished."

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*The Treatment of Gas Asphyxia.*

Dr. Chassevant has recently explained the treatment he adopts in his ambulance for the victims of gas asphyxiation, which has given good results in his hands. The patients reached the ambulance, which was acting as evacuation hospital for the first line, from two to eight hours after being gassed. Some had already received first aid at a dressing-station or at other ambulances; some came straight from the trenches. All were subjected, at several sittings with intervals between, to the rhythmic inhalation of oxygen under pressure. Dr. Chassevant holds that oxygen inhalation as usually administered with an india-rubber bag has no efficacy; it is essential actually to insufflate oxygen on the lines of Dr. D'Arsonval's treatment of carbonic oxide intoxication. An india-rubber catheter is introduced far back into the buccal cavity, directly connected with the cylinder of compressed oxygen (such as is available at the pharmacies as reserve oxygen); by opening and shutting the regulator key active rhythmic insufflation at the rate of 15 or 16 to the minute is brought about. This treatment calms the dyspnoea, favours pulmonary aeration, and may be regarded as a true mechano-therapy treatment of the lung. Doctors and pharmacists who have been accidentally subjected to chlorine inhalation in the laboratory or on the field know how painful is the effort of inspiration; it is just this effort which the inhalation of compressed oxygen renders unnecessary. To combat the cardiac weakness Dr. Chassevant accompanies the inhalation of oxygen with subcutaneous injection of camphorated oil in large doses, 5 to 15 c.c. or more in 24 hours, as occasion requires. The author states that this method of treatment has been adopted by all to whom he has explained it. Oxygen under pressure is, in his view, the true antidote to intoxications arising from inhalation, assuring as it does the proper ventilation of the lungs. It is therefore desirable for every ambulance and dressing station to have at disposal several small and easily managed cylinders of compressed oxygen under pressure; they might even be available in the shelter-posts along with the portable fire-extinguishers.

*Fractures of the Humerus in Grenade-throwers.*

M. Chaput has reported to the Surgical Society the observations of MM. Kas and Rouéche on fractures of the humerus in grenade-throwers, specially frequent in the case of the instructor—i.e., men who have frequently repeated the same movement. The mechanism is the usual one of fracture by muscular violence; the humerus breaks by flexion inwards. In one case the length of the internal fragment allowed the movement of the arm to be completed. These fractures are presumably of quite spontaneous occurrence. Syphilis may play a part; but union occurs within a normal period.

*Parasitic Haemoptysis in the Yellow Races.*

MM. Salomon and Neveu have found, in the bloody expectoration of a native of Annam who showed signs of generalised afebrile bronchitis with apical congestion, the valvular eggs of a fluke, the *Paragonimus westermani* (*Distoma pulmonale*). The eggs contained pigment, and were clustered in groups of 30 to 40. The expectoration also contained cocci, erythrocytes, and numerous eosinophiles. An eosinophilia of 7 per cent. was present in the circulating blood. Radioscopy indicated the existence of fairly well-marked enlargement of the hilus glands. The authors place this case in the same category with three other cases of recurrent haemoptysis in Indo Chinese who had no stethoscopic signs of pulmonary bacillosis, nor any obvious lesions of the air tubes, but presented clinical signs of bronchitis accompanied by emphysema. The expectoration consisted of scanty coloured pellets floating in abundant sanguinolent mucus. Pulmonary distomiasis or infection with *Paragonimus westermani* is endemic in the Far East and in those parts of North America inhabited by Chinese or Japanese. The condition is frequently accompanied with bronchitis or bronchiectasis. It may give rise to cavitation and simulate pulmonary tuberculosis, both in auscultatory signs and in the resulting cachexia. The parasite is frequently harboured and disseminated by domestic animals—the pig, dog, and

cat. The presence on the French front of native soldiers and labourers from the Far East should direct the attention of medical men to these carriers of flukes, who are certainly numerous and might give rise to endemic distomiasis in France. Cases of protracted bronchitis with or without haemoptysis which have been in contact with the subjects of pulmonary distomiasis must be held suspect. Microscopical examination of the sputa, by establishing the existence in abundance of the characteristic eggs of the *Paragonimus*, permits of the prompt isolation and discharge of the infected person. It is important not to overlook these cases, which in the Far East give rise to considerable sickness and mortality.

March 27th.

## CANADA.

(FROM OUR OWN CORRESPONDENT.)

*The Medical Profession in Canada and the War.*

ACCORDING to a statement recently issued by Sir Edward Kemp, Canadian Minister of Militia and Defence, the Canadian Army Medical Corps number approximately 1800, of whom 500 are in Canada and the balance serving overseas. A large proportion of those in Canada are carrying on the work of the Canadian Military Hospitals Commission. In addition to the above numbers there are 400 civilian practitioners partially employed in military work in Canada, and over 400 Canadian doctors have proceeded overseas to join the Royal Army Medical Corps. In a short time other physicians in the Dominion desirous of serving will be given an opportunity of assisting in the work of attending invalided-soldiers returning to Canada. That work is now to be divorced from the Canadian Hospitals Commission and assumed by the Canadian Army Medical Corps, under the direction of a Director of Medical Services for Invalids, Commission continuing the provision of hospital accommodation as it is needed, and the maintenance and equipment thereof. Colonel Frederick W. Marlow, A.D.M.S., has made an official report to the Militia Department on the general arrangements of the Canadian Army Medical Corps. Travelling all over Canada, Colonel Marlow's work of inspection had a wide scope. His report has been considerably discussed since the Canadian Government made it public property. In general, Colonel Marlow recommends: The completion of the reorganisation of the Medical Service, thus bringing the medical branch of the service up to the required standard; the increasing of administrative staffs; the appointment in some districts of officers brought back to Canada from overseas; consideration of the advisability of increasing the Permanent Army Medical Corps for duty in Canada; frequent inspections of all districts and camps, for which purpose the appointment of an inspecting officer would seem advisable; dépôt units of fixed establishment to replace or supplement the present reinforcement plan, and closer relation between home and overseas service so as to minimise wastage; a plan whereby specialists may proceed overseas without undue delay in Canada; the gradation of officers entering the service, so that experience and special ability will count; the advisability of providing term contracts for service; improvement of laboratory facilities; installation of fumigating plants at camps and military hospitals; close co-operation between the Canadian Hospitals Commission and the Canadian Army Medical Corps; and the establishment of large hospitals in Halifax, Quebec, Montreal, Toronto, Winnipeg, Edmonton, and Vancouver. One of the recommendations, that of the transference of the returned soldiers to the Canadian Army Medical Corps from the Hospitals Commission, has already been adopted.

*The Freedom of the Canadian Expeditionary Force in Canada from Enteric Fever.*

The Provincial Board of Health for Ontario has supplied to date all the typhoid and paratyphoid vaccine used by the entire Canadian Expeditionary Force, about 450,000 men. In all, nearly 600,000 doses have been supplied free of cost. The Department of Militia and Defence have just announced that for the 12 months ending Dec. 31st, 1916, 167 cases only of typhoid fever were reported as having occurred amongst the thousands of men of the C.E.F., and this notwithstanding the fact that typhoid fever is a disease especially affecting young adults from 17 to 30 years of age,

and a disease which is endemic in all parts of Canada. This comparative freedom on the part of the force is seen to be most striking when it is recalled that, during the Boer War, one man out of every nine in the British Forces in South Africa was invalided through this disease, and that in the Spanish-American War, of 107,000 men in the camps at Tampa, Florida, and elsewhere, who had not left the shores of the United States, 20,000 contracted the disease. The remarkable change can only be attributed to the process of inoculation, and Dr. John W. S. McCullough, chief medical officer of health of the Province of Ontario, may be congratulated on the good results of systematic work.

#### *Canadian Medical Association.*

It has been decided to resume the annual meetings of the Canadian Medical Association, which have been suspended since the beginning of war in 1914. Dr. J. W. Scane, registrar of the Medical Faculty of McGill University, has been acting as general secretary since the departure of Dr. W. W. Francis for overseas service. Dr. A. D. Blackader has been elected President. The Past-President, Dr. Francis J. Shepherd, will deliver the address in surgery, and Dr. A. Mackenzie Forbes, who has recently returned from the front, has been appointed chairman of the Military Section. He has been promised a number of interesting papers from Canadian surgeons at present in England and France. The annual meeting is to be held in Montreal in the middle of June.

#### *McGill University and the War.*

The 43 graduates of class '17, McGill University, in medicine, have volunteered in a body to go overseas. Twenty-four are in a position to go overseas immediately, and the balance have started training. Old boys and present boys to the number of 1800 have been serving their King and country in the present great world conflict. Of those who have gone 132 have made the supreme sacrifice, and 163 have been wounded. One of the faculty has received the Victoria Cross, four the D.S.O., one C.M.G., one the Order of the Bath, and seven have been mentioned in despatches. Amongst professors and graduates who had recently had their names brought to the attention of the Secretary of State were Lieutenant-Colonel F. G. Finley, Captain James R. Goodsall, Colonel Lorne Drum, Major Lewis E. W. Irving, and Captain G. C. Hale.

#### *Medical Inspection of Schools in Toronto.*

About a year ago it began to be felt in Toronto that there was a waste of money in having medical inspection of school children conducted under the Board of Education. The City Council unanimously passed a resolution favouring the placing of medical inspection under the administration of the Board of Health. Although numerous conferences were held between the Board of Health of Toronto, the Board of Education, and the Provincial Government, no definite and satisfactory arrangement could be arrived at, as the Board of Education was strong for retaining the system they had adopted under their own immediate management. Ultimately the matter has been laid before the electors, when the people, by an overwhelming majority, voted in favour of medical inspection being placed under the Board of Health. Legislation will be sought at the present session of the Ontario legislature to provide for the transfer of responsibility.

Toronto, March 5th.

**ROYAL SOCIETY OF ARTS: INDIAN SECTION.**—At a meeting of the section held on March 27th Sir Havelock Charles, President of the Medical Board of the India Office, read a paper by Surgeon-General Sir C. Pardey Lukis, Director-General, Indian Medical Service, on Opportunities for Original Research in Medicine in India. The paper stated that there would shortly be two schools of tropical medicine in India—one at Calcutta and the other at Bombay. The former would be opened under the directorship of Sir Leonard Rogers as soon as the cessation of hostilities enabled them to furnish the necessary staff. The latter was associated with the Bombay Bacteriological Laboratory at Parel and was also approaching completion. The Government of Madras also had under consideration a scheme for founding a pathological institute in connexion with the Madras Medical College. Mr. Austen Chamberlain, who presided, appealed to the leaders of the medical profession in this country to make themselves acquainted with the opportunities offered by India, and not to grudge sending to India some of the best pupils they could produce.

## THE SERVICES.

### ROYAL NAVAL MEDICAL SERVICE.

The following appointments have been notified:—  
Fleet Surgeons: M. H. Knapp to *Inflexible*, and C. C. Macmillan, D.S.O., to *Bake*.  
Temporary Surgeon: M. Neilson, to *Vivid*.

### ROYAL ARMY MEDICAL CORPS.

Col. J. Turton (T.F. Res., A.M.S.) to be temporary Major.  
Lieut.-Col. J. G. Gill to be acting Colonel whilst employed as Deputy Director of Medical Services of a Division.  
To be acting Lieutenant Colonels: Major F. E. Roberts, D.S.O., whilst commanding a Stationary Hospital; Major E. F. Q. L'Estrange whilst commanding a Field Ambulance.

Major Sir J. Bland-Sutton, R.A.M.C., T.F., to be temporary Honorary Lieutenant-Colonel.

Capt. E. W. H. Groves, R.A.M.C., T.F., to be temporary Major.  
Temporary Lieutenants to be temporary Captains: T. Mulcahy, J. M. N. Paton, W. A. Berry, W. S. Melville, A. T. Gibb, E. H. Cameron, H. V. A. Gatchell, G. Macdonald, J. H. S. Sheppard-Jones, A. S. Burgess, R. P. Smith, W. M. McLaren, A. D. Morris, C. K. Carroll, C. B. Tudhope, A. Sandison, D. P. Thomas, A. G. Alexander, W. G. Harnett, A. J. Chillingworth, H. M. Harrison, R. A. Quinn, J. I. Bright, J. G. T. Thomas, B. S. Simmonds, D. S. Graham, A. A. E. Newth, J. R. Wyllie, H. W. Harding, G. C. B. Hawes, C. W. Morrison, J. S. Annandale, A. Morgan, J. T. H. Madill, N. J. Judah, J. B. Yelf, J. F. MacKenzie, J. K. Manlove, C. O'Malley, C. Townsend, J. B. Galligan, D. T. Evans, J. G. Lee, P. A. McCallum, W. Scott, H. Nuttall, J. Cathcart, W. G. Thomas, E. B. Morley, G. L. Lawlor, J. B. Fairclough, F. C. Conran, R. E. McLaren, S. R. Prall, H. C. Lindsey, W. Thomas, E. J. Dermott, D. G. Suttie.

To be temporary Captains: W. A. Brown, J. A. Glover (late temp. Capt.), F. W. Jackson, A. T. Wysard (Staff-Surg., R.N., retired), M. McK. McRae.

H. Maclean to be temporary Honorary Captain.

Temp. Lieut. C. J. B. Pasley, from General List, to be temporary Lieutenant.

To be temporary Lieutenants: R. McCaffrey, A. B. Jones, A. R. Leggate, B. P. Hynes, A. L. Candler, F. J. Lawson, L. J. Spence, J. Acomb, T. Howell, F. W. Hartley, S. Upton, R. J. Dick, W. H. Bonnett, W. H. Orton, P. J. Montgomery, W. L. Tindie, T. A. Jones, A. V. Boyall, G. B. Measenger, G. T. Bogle, J. S. Clark, F. W. Chesnaye, S. Blake, T. Crawford, L. C. Rivett, A. Denham, F. J. Waldmeier, J. M. Shaw, R. Young, A. W. Laing.

W. R. Rowlands to be temporary Honorary Lieutenant whilst employed with the British Red Cross Hospital, Neyley.

Officers relinquishing their commissions: Temp. Capt. J. W. Hutton, S. A. Montgomery, A. C. Turner, R. A. Hughes, G. J. W. Keigwin, Temp. Lieuts. W. Butement, E. G. Barker, D. H. Foley, E. Beavley, F. D. Crew, G. W. Young, H. Hannigan, H. T. Finlayson, C. H. F. Bailey, R. N. Hartley, J. Porteous, A. J. D. Rowan, T. E. Davey, E. K. Williams, and J. Watt, and W. Leslie (on account of ill-health).

### SPECIAL RESERVE OF OFFICERS.

Lieutenants to be Captains: H. Chadwick, T. O'Mahony, G. G. Drummond.

W. F. Mason, from Leeds Univ. Cont., O.T.C., to be Lieutenant.

Lieutenant on probation D. Stewart is confirmed in his rank.

### TERRITORIAL FORCE.

Capt. (temp. Major) W. D. Watson to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Lieuts. A. H. T. Andrew and C. Jephcott to be Captains.

Capt. (temp. Major) C. Corfield relinquishes his temporary rank on alteration in posting.

Lieut. P. W. G. Sargent is seconded whilst holding a temporary commission in the R.A.M.C.

## URBAN VITAL STATISTICS.

(Week ended March 24th, 1917.)

**English and Welsh Towns.**—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18,000,000 persons, the annual rate of mortality was 16·6, against 17·1 and 18·5 per 1000 in the two preceding weeks. In London, with a population exceeding 4,000,000 persons, the death-rate was 17·5, or 1·8 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 7·6 in Gloucester, 8·7 in Coventry, and 9·0 in Ilford, to 22·7 in Walsall and in Middlesbrough, 23·2 in Eastbourne, and 23·3 in Gateshead. The principal epidemic diseases caused 381 deaths, which corresponded to an annual rate of 1·1 per 1000, and included 228 from measles, 52 from infantile diarrhoea, 47 from diphtheria, 42 from whooping-cough, 7 from scarlet fever, and 5 from enteric fever. The deaths from measles showed a further increase compared with the numbers recorded in the eight preceding weeks, and caused the highest annual death-rates of 2·2 in Plymouth and in Warrington, 2·4 in Wigan, and 3·4 in Walsall. The 817 cases of scarlet fever and the 1477 cases of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 12 and 1 above the numbers at the end of the previous week. Of the 5496 deaths from all causes in the 96 towns, 166 resulted from violence. The causes of 51 of the total deaths were uncertified, of which 12 were registered in Birmingham, 4 in Manchester, and 3 each in London, Stoke-on-Trent, Liverpool, and Gateshead.

**Scotch Towns.**—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death-rate was equal to 16·2, against 16·7 and 18·3 per 1000 in the two preceding weeks. The 348 deaths in Glasgow corresponded to an annual rate

of 16·3 per 1000, and included 28 from whooping-cough, 13 from measles, 6 from infantile diarrhoea, and 1 from diphtheria. The 117 deaths in Edinburgh were equal to a rate of 18·4 per 1000, and included 7 each from measles and whooping-cough, and 1 from infantile diarrhoea.

*Irish Towns.*—The 201 deaths registered in Dublin were equal to an annual rate of 26·3, or 2·3 per 1000 above that in the previous week, and included 17 from measles, 4 from whooping-cough, and 1 from enteric fever. The 156 deaths in Belfast corresponded to an annual rate of 20·7 per 1000, and included 4 from measles and 3 from infantile diarrhoea.

#### VITAL STATISTICS OF LONDON DURING FEBRUARY, 1917.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 4·2 per 1000 of the population, estimated at 4,310,030 persons in the middle of the year; in the three preceding months the rates were 5·0, 3·9, and 4·0 per 1000 respectively. The lowest rates last month were recorded in Kensington, Chelsea, St. Marylebone, Battersea, and Wandsworth; and the highest rates in Paddington, Holborn, the City of London, Shoreditch, and Southwark. The prevalence of scarlet fever showed a slight increase over that recorded in the two preceding months; this disease was proportionally most prevalent in Paddington, Hammersmith, Islington, the City of London, Shoreditch, Bethnal Green, Battersea, and Lewisham. The Metropolitan Asylums Hospitals contained 811 scarlet fever patients at the end of the month, against 1066, 913, and 300 at the end of the three preceding months; the weekly admissions averaged 111 last month, against 95 in each of the two preceding months. The prevalence of diphtheria showed no variation from that recorded in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent last month in Holborn, the City of London, Stepney, Southwark, Bermondsey, Deptford, and Greenwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1543, 1479, and 1420 at the end of the three preceding months, had risen again to 1453 at the end of last month; the weekly admissions averaged 166, against 187, 143, and 168 in the three preceding months. Enteric fever was rather more prevalent than it had been in other recent months; the 35 cases notified during February included 4 in the City of Westminster, 4 in Camberwell, 3 in Paddington, 3 in Kensington, 3 in Stepney, 2 in Fulham, 2 in Bermondsey, and 2 in Wandsworth. There were 29 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 37 and 35 at the end of the two preceding months; the weekly admissions averaged 4, against 5 and 6 in the two preceding months. Erysipelas was proportionally most prevalent in Paddington,

Kensington, St. Pancras, Poplar, Southwark, and Woolwich. The 16 cases of puerperal fever notified during the month included 2 in Hackney, 2 in Southwark, 2 in Battersea, and 2 in Woolwich. The 61 cases of cerebro-spinal meningitis included 6 in Islington, 5 in Bethnal Green, 5 in Lambeth, 4 in Southwark, and 4 in Camberwell; while of the 8 cases notified as poliomyelitis 2 belonged to Islington and 2 to Lambeth.

The mortality statistics relate to the deaths of persons actually belonging to the several metropolitan boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the four weeks ending March 3rd the deaths of 7039 London residents were registered, equal to an annual rate of 21·3 per 1000; in the three preceding months the rates were 14·5, 22·6, and 18·4 per 1000 respectively. The death-rates during the month ranged from 16·1 in Hampstead, 16·6 in Lewisham, 18·3 in Woolwich, 18·2 in Hackney and in Wandsworth, and 18·9 in Hammersmith, to 23·5 in Kensington, 24·7 in Finsbury, 25·4 in St. Marylebone, 25·6 in Bermondsey, 26·0 in Southwark, and 26·5 in Shoreditch. The 7039 deaths from all causes included 386 which were referred to the principal infectious diseases; of these, 204 resulted from measles, 9 from scarlet fever, 55 from diphtheria, 42 from whooping-cough, 5 from enteric fever, and 71 from diarrhoea and enteritis among children under 2 years of age. No death from any of these diseases was recorded last month in Hampstead or in the City of London; they caused the lowest death-rates in Kensington, Stoke Newington, Finsbury, Lewisham, and Woolwich; and the highest rates in Fulham, St. Marylebone, St. Pancras, Southwark, Bermondsey, Lambeth, and Camberwell. The 204 deaths from measles were 57 above the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal last month in Fulham, St. Marylebone, St. Pancras, Southwark, Bermondsey, and Camberwell. The 9 fatal cases of scarlet fever were only half the average number, and included 2 in Deptford and 1 each in Fulham, Hackney, Shoreditch, Poplar, Southwark, Lambeth, and Wandsworth. The 55 deaths from diphtheria were 4 in excess of the corrected average number; this disease was proportionally most fatal in Hammersmith, Islington, Stepney, Southwark, and Deptford. The 42 deaths from whooping-cough were 72 fewer than the average; the highest death-rates from this disease last month were recorded in Paddington, Islington, Southwark, Lambeth, Battersea, and Wandsworth. The 5 fatal cases of enteric fever showed a decline of 6 from the average number, and included 2 in Stepney and 1 each in the City of Westminster, Hackney, and Battersea. The 71 deaths from diarrhoea and enteritis among children under 2 years of age were slightly fewer than the average; the mortality from this cause was proportionally greatest in Paddington, Chelsea, the City of Westminster, St. Pancras, Islington, Hackney, Shoreditch, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London during the month from these principal infectious diseases was 7·5 per cent. above the average.

#### ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING FEBRUARY, 1917.

(Specially compiled for THE LANCET.)

CITIES AND BOROUGHS.	Estimated civil population, 1915.	Notified Cases of Infectious Disease.										Deaths from Principal Infectious Diseases.												
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other con-tinued fevers.	Puerperal fever.	Erysipelas.	Cerebro-spinal meningitis.	Poliomyelitis.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Enteric fever.	Diarrhoea and enteritis (under 2 years).	Total.	Annual rate per 1000 persons living.	Deaths from all causes.	Death-rate per 1000 living.

"Audi alteram partem."

### "SOLDIER'S HEART."

*To the Editor of THE LANCET.*

SIR.—Captain Adolphe Abrahams's paper on "Soldier's Heart," published in your issue of March 24th, is one which has interested me very greatly. With many of his points of view I am in entire sympathy; in none more so than when he discusses the effect of strain upon the heart. The inherent improbability that so vital a muscle as that of the healthy heart is materially exposed to damage during physical effort is so obvious that the strongest evidence of such damage must be forthcoming before the hypothesis of strain can become acceptable. There is no doubt in my mind that in a number of the earlier records of dilatation following effort such dilatation resulted from a paroxysm of tachycardia, great acceleration of the heart's action, and acceleration of pathological type; certainly that has been the cause of dilatation in all the cases of so-called strain with sudden dilatation which I have seen. Such paroxysms are unquestionably provoked by effort, but only, I believe, when there is a pre-existing defect in the heart. Amongst a group of 558 cases of so-called "D.A.H." admitted to the Military Hospital, Hampstead, last year the histories associate the onset of the symptoms with sudden effort in five instances only. There can be little disagreement that effort aggravates the symptoms, and that effort displays defects which are latent, but that it is responsible for the condition which Captain Abrahams describes is not to be believed upon the evidence which is before us. Captain Abrahams claims a wide experience of athletes, and his statements in regard to them form a valuable contribution to the subject discussed; he would do all those who are interested in cardiac problems a considerable service if at some future date he would describe his experience at greater length.

When Captain Abrahams states, in discussing the value of murmurs in estimating the soldier's fitness for duty, that the heart's capacity for doing work is the vital criterion our observations at Hampstead bear out his statement completely. In a group of 462 patients at Hampstead 266 were entirely free from cardiac murmurs, while 196 presented systolic murmurs over some valve area. These patients were all classified as to their capacity for duty by testing their tolerance to physical drill and route marches extending over many weeks. Of the 266 presenting no murmur (the controls) 154, or 58 per cent., were considered on the basis of exercise tests to be permanently unfit for duty, while 42 per cent. were returned to duty. Of the 196 men presenting murmurs 101 (or 52 per cent.) were judged on the same basis to be unfit and 48 per cent. returned to duty. The group of cases has been further subdivided according to the situation of the murmur, its conduction, &c., but the balance remains the same between the fit and the unfit—namely, approximately 50 per cent. each way. In a report about to be issued by the Medical Research Committee I have therefore concluded that "the presence or absence of systolic murmurs is of no value in estimating the soldier's capacity for work."

Lastly I come to a statement of Captain Abrahams which concerns a recent publication by myself and co-workers. He states that "Recently 'soldier's heart' has been attributed to deficiency of buffer-salts in the blood." This statement cannot be allowed to pass without correction. In an article written in conjunction with Cotton, Barcroft, and others, our belief is stated that breathlessness may be due to this cause. That is, as I am sure Captain Abrahams will on consideration agree, a different statement from that which he attributes to us. It is true that our conclusion applies to breathlessness as we have seen it in "those who are diagnosed as 'irritable hearts'"; but we nowhere imply that a deficiency of "buffer-salts" is the whole condition, nor do we imply that the same change may not be found in the future in distinct conditions. Neither do we attempt, as may be inferred from Captain Abrahams's article, to ascribe "symptoms of cardiac disease" to a deficiency of these salts. Indeed there is nothing in our article which suggests that we

believe any of the symptoms of the condition discussed emanate from cardiac disease. We deal with one symptom only—namely, breathlessness—and in so far as we deal with this we express the view that it is not cardiac in origin.

I am, Sir, yours faithfully,  
THOMAS LEWIS.

Military Hospital, Hampstead, March 24th, 1917.

## THE MOBILISATION OF THE DENTAL PROFESSION.

*To the Editor of THE LANCET.*

SIR.—The dental profession cannot fail to appreciate the views expressed in the leading article in THE LANCET of March 10th, and let us hope that our authorities will at last see that the best and least expensive manner to meet the needs of the Army is to organise a proper Army Dental Corps as other nations have done. It is quite correct that there are only 5000 qualified men, but it must not be supposed that if all of them were mobilised there would be nobody left to attend to the needs of the community. The bulk of the dental work in England is done by unqualified men, the exact number of whom is unknown, but is sometimes quoted as high as 40,000. These men may not call themselves dentists or dental surgeons, but they are free to practise, for our law does not protect the qualified man nor prohibit the unqualified from practising. The services of these men could not be used in the treatment of the soldiers, but many of them are skilled mechanics, and they could serve in that capacity.

In view of the great shortage of qualified men available for Army service, the first thing to do is to stop the wasteful use of the practitioners who have been drafted into the combatant ranks. Some of them have already been killed, but the remainder should be withdrawn from the ranks and utilised in their own special work.

I am, Sir, yours faithfully,  
F. NEWLAND-PEDLEY.

## SPECIFICITY IN ANTISEPTICS.

*To the Editor of THE LANCET.*

SIR.—There can be no doubt that the question raised by Dr. Kenneth Taylor in your issue of Feb. 24th—namely, that of the specificity of an antiseptic—is an important one, and must be kept in view in dealing with the practical problem of wound treatment. But almost of equal importance is the question of the specificity of the medium for the organism and of the antiseptic for the medium. The specificity of the medium for the organism Dr. Taylor acknowledges, when, for his experiments, he chooses "fluid medium suitable for the organism." If he had employed another medium I feel confident that he would have had very different results.

Regarding the specificity of the antiseptic for the medium, it has been shown that many antiseptics which act well in serum or other media suitable for the growth of organisms become practically inert when they react with pus. For this reason the hypochlorites are practically useless as "dressing solutions" except to ensure asepsis, while as irrigation lotions, when they are in too great bulk to be completely quenched, they appear to be excellent. I would suggest, therefore, that in our experiments on antisepsis we should direct our attention to media as like those in which the organisms thrive in a wound as it is possible to get. Infected pus or blood provides such a medium, for these contain, for practical purposes, all the elements of tissue except the fibrous stroma. If pus is used it should contain one or two organisms per field; if blood is used it should be defibrinated, inoculated with a small volume of a suspension of organisms, and incubated a short time to allow some phagocytosis to take place. Such a blood medium can readily be standardised so as to give comparative results. As in Dr. Taylor's experiment, the inhibiting strength of the antiseptic in such a medium serves well to give an estimate of its potency. It is noteworthy that, as a rule, an antiseptic is more effective if phagocytosis has not been allowed to take place—i.e., when the organisms are in serum.

One other point I would raise. In reference to "physiological treatment" Dr. Taylor, who has already severely

criticised the claims made for hypertonic saline, now describes the application of physiological saline as a method of "passive treatment" and "a purely negative one." He thus shows clearly that he does not agree with the author of physiological treatment who says "that the white corpuscles are carried forward by a chemotactic movement in the direction of the free surface upon which the physiological solution has been imposed." This, and the statements regarding the physical action of hypertonic saline, I have shown to have no sound experimental foundation. If clinically the physiological methods are satisfactory, we are faced by the problem of finding the true explanation.

I am, Sir, yours faithfully,

Warrington, Feb. 23th, 1917.

WM. PARRY MORGAN.

## THE CLOSURE OF COLOTOMY OPENINGS.

To the Editor of THE LANCET.

SIR.—In connexion with Mr. Lockhart-Mummery's paper in your issue of March 10th, and the subsequent correspondence on this subject, I have looked up the statistics of the cases operated upon in the Royal Infirmary, Sheffield, during the years 1906–1916. The method adopted in all but one has been that described by Professor Sinclair White in your issue of March 24th. The one exception was that in which an enterotome was used to destroy the spur. I was resident surgical officer at the time. The special type of instrument was obtained which Mr. Lockhart-Mummery designates as the best, "in which a male blade fits into a double female blade, the blades being of thin steel with a waved edge." The patient developed peritonitis due to sloughing of the gut, and only after a long and anxious convalescence did he recover. Since then the enterotome has not been used in any case.

The number of cases in the period is 38, with one death. I have seen many of these cases subsequently in the out-patient department, and in no case have they complained of a weak spot in the abdominal wall which might necessitate the wearing of a belt. I only know of one of these cases subsequently developing intestinal obstruction. It was due to the gut becoming involved in secondary carcinoma well above the position of the closed colotomy opening. The operation, if done as described by Greig Smith and quoted by Professor Sinclair White, is not regarded by us as one fraught with severe risk to the patient.

From experience in the after-treatment of these cases during the past ten years as a resident officer and otherwise, I know that every endeavour should be made to keep the bowels from acting as long as the comfort of the patient will permit. Mr. Lockhart-Mummery does not state what the subsequent trouble is likely to be if the bowels do not act on the second day after operation. I respectfully suggest that if they are made to act as a routine on the second day, then the number of failures in closing a colotomy opening will be much increased.

I am, Sir, yours faithfully,

ERNEST FINCH,

March 26th, 1917. Assistant Surgeon, Royal Infirmary, Sheffield.

## SIMPLE ULCER OF THE OESOPHAGUS.

To the Editor of THE LANCET.

SIR.—I am interested in Dr. J. B. Christopherson's case of simple ulcer of the oesophagus published in your issue of March 10th. During an experience of 12 years as pathologist to large hospitals I have come across two such cases. In one case which I published in 1912,<sup>1</sup> the ulcer was situated immediately above the cardiac orifice of the stomach, and it ruptured into the mediastinal tissues and then into the left pleura, the man dying from pyopneumothorax. The patient had suffered from gastric disturbance for two years previously. Since then I have had another case, also in a man, who had suffered from gastric pain after food for six years. He developed severe haematemesis two days before death. At the post-mortem, an ulcer one inch in length was found immediately above the cardiac orifice. In addition, there were several cicatrices in the neighbourhood, as in Dr. Christopherson's case. There was a fine cirrhosis of the liver, but no evidence of varicosity of

the oesophageal veins. The vessel opened into was a small one. There were no ulcers in the stomach or duodenum.

I must say that I fail to see the force of Dr. Christopherson's arguments in favour of the condition in his case being due to typhoid fever contracted six years previously. I have never seen typhoid ulceration in such a situation, and it is generally recognised that these oesophageal ulcers probably have a similar origin to the peptic ulcer of the stomach. Glynn<sup>2</sup> has drawn attention to the frequency with which superficial lesions occur in the oesophagus in association with severe vomiting. It may be, therefore, that chronic gastric catarrh associated with vomiting initiates the condition which ultimately leads to ulceration.

I am, Sir, yours faithfully,

Oraigleath, March 22nd, 1917.

JAMES MILLER, M.D.

## THE CRIMINAL LAW AMENDMENT BILL.

To the Editor of THE LANCET.

SIR.—This Bill is at present being discussed by a committee of the Commons, and the consideration of Clause 2 has been postponed. As readers may be aware, this clause proposes a penalty up to 24 months with hard labour if a venereal person has sexual relations—provided he shall not be punished if he or she has "reasonable grounds" for believing that he or she is free from venereal.

In connexion with this proviso, would it not be well if a clause were added that any doctor receiving a written report from a bacteriologist relating to a blood, pus, or tissue test must retain such report, and must not hand it to a patient? Now, if some 6 to 10 millions of venereals get a hold of such reports and show them to persons immediately concerned much evil may be caused; there could be a good market with pros. and semi-pros. of these. Also a penalty should be provided against such sales, transfers, loans, and otherwise. I am, Sir, yours faithfully,

Liverpool, March 18th, 1917. ROBERT R. RENTOUL, M.D.

PS.—Is it too late to hope that all the clauses relating to brothel-keeping, soliciting, indecent assault, rape, &c., be deleted from this Bill, and that it be made a Public Health Act, relating to venereals only?

## ECONOMY IN RUBBER GLOVES.

To the Editor of THE LANCET.

SIR.—Some years ago I used myself to repair my car tyres by vulcanisation, and being struck by the waste of punctured and torn rubber gloves at a local hospital I was led to experiment in the repair of these gloves by vulcanisation. In course of time I elaborated a suitable electric vulcaniser, and approached some surgical-instrument firms with the idea of putting it on the market. Technical difficulties intervened, however, and it was found to be more convenient to get a firm of repute to undertake the repairs with the apparatus.

For several years now many hospitals, military and civil, have effected a considerable saving, perhaps as high as 50 per cent., in their glove bill by this means. As a big hospital may spend £100 or more a year on gloves, it is obvious that here to hand is a ready means of effecting economy with no loss of efficiency. The repairs thus effected have the following advantages over patches simply stuck on with rubber solution: 1. The patches are so small as to be almost impalpable. 2. They do not come off, even after repeated sterilisations. 3. A new finger can be put on a glove; for instance, the right forefinger of a glove is often lacerated badly and needs renewal. 4. A long slit can be repaired, or a new wrist affixed, or two lacerated gloves made up into one good one.

The repairs are undertaken by Messrs. W. and A. Bates, Rubber Mills, Leicester.—I am, Sir, yours faithfully,

N. I. SPRIGGS, M.D. Lond., F.R.C.S. Eng.,  
Leicester, March 26th, 1917. Captain, R.A.M.C. (T.).

<sup>1</sup> Proceedings of the Pathological Society of Great Britain and Ireland, 1914.

THE Wounded Allies Relief Committee, 8, Grosvenor-gardens, S.W., has presented to the Serbian Relief Fund the sum of £500, to be spent exclusively on providing food for sick and wounded Serbian prisoners of war in Germany.

# The War.

## THE CASUALTY LIST.

The following names of medical officers appear among the casualties announced since our last issue:—

### Killed.

Capt. W. B. Clark, R.A.M.C., attached Scots Guards, was a student at King's College Hospital, and qualified in 1903 at London University. He joined the R.A.M.C. in October, 1914, and was killed by the bursting of a shell whilst doing duty with the Scott Guards.

Capt. E. Robinson, R.A.M.C.

### Wounded.

Capt. A. F. Wilson, R.A.M.C., attached York and Lancaster Regiment.

Capt. W. B. Purchase, R.A.M.C., attached Royal Field Artillery.

Capt. F. G. Thatcher, R.A.M.C.

Capt. P. S. Blaker, R.A.M.C.

Capt. E. H. Moore, D.S.O., R.A.M.C.

## THE HONOURS LIST.

The following awards to medical officers are announced:—

### Distinguished Service Order.

Temp. Surg. Harold Boulbee Padwick, R.N.

For conspicuous gallantry and devotion to duty. He remained in the open, and continued to tend the wounded under very heavy fire. Later, he proceeded to Headquarters, and at great personal risk brought in many wounded men. He displayed great courage and determination throughout the operations.

### Bar to Military Cross.

Temp. Capt. Archibald Stirling Kennedy Anderson, M.C., R.A.M.C., attached R.N. Field Ambulance.

For conspicuous gallantry and devotion to duty. He rendered most valuable services while in command of a bearer subdivision, in assisting to collect wounded from a forward area under very heavy fire. (The award of the Military Cross was announced in THE LANCET of Sept. 2nd, 1916, p. 450.)

### Military Cross.

Temp. Lieut. Herbert John Davidson, R.A.M.C., attached R.N. Field Ambulance.

For conspicuous gallantry and devotion to duty. He tended the wounded in a forward area under very heavy fire. He set a splendid example to all ranks.

Capt. Robert Andrew Kerr, R.A.M.C., attached Royal Warwickshire Regiment.

For conspicuous gallantry and devotion to duty. He succeeded in rescuing his three bearers, who were entombed when the aid-post was blown in. He constantly visited the most dangerous parts of the line in order to tend the wounded.

Temp. Lieut. Allan George Reid, R.A.M.C., attached R.N. Field Ambulance.

For conspicuous gallantry and devotion to duty. He tended the wounded under very heavy fire, and worked continuously for 36 hours in command of a bearer subdivision which was operating in a forward area.

Capt. Norman Craig Shierlaw, Australian A.M.C., R.M.C., Australian Infantry.

For conspicuous gallantry and devotion to duty. He continually attended to the wounded for two days and nights under heavy fire. He has on many previous occasions done fine work.

**Foreign Decoration.**—The President of the French Republic has conferred the Croix de Guerre avec Palme upon Surgeon J. D. Milligan, R.N.

The name of Surgeon J. D. Milligan is also mentioned in a despatch dealing with naval matters.

## DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

Second Lieut. J. H. Cotterill, Black Watch, youngest son of Lieut.-Col. J. M. Cotterill, R.A.M.C., of Edinburgh.

Second Lieut. R. M. Ross, Worcestershire Regiment, youngest son of Dr. D. M. Ross, of Brighton.

Capt. W. B. Clark, R.A.M.C., younger son of Dr. G. B. Clark, formerly M.P. for Caithness.

Capt. E. P. Turner, Royal Field Artillery, younger son of Surgeon-General G. R. Turner, of Radlett, Herts.

## HOSPITAL SHIP TORPEDOED.

The British hospital ship *Asturias* was torpedoed without warning on the night March 20th-21st. She had previously landed about 900 sick cases. The casualties amongst the medical services included 11 dead, 3 missing (including 1 female staff nurse), and 17 injured. Between 300 and 400 survivors were landed; some were injured by the explosion and 3 died after being landed.

**WAR HOSPITAL WORK IN HAMPSHIRE.**—A meeting under the auspices of the British Red Cross Society was held at Winchester on March 21st. The county director, Mr. Lockhart Stephens, reported that there were in Hampshire 53 auxiliary hospitals, 9 of which were under the control of the Order of St. John, 33 under the Red Cross Society, and the remainder promoted and largely maintained by private individuals. The accommodation was about 2000 beds, and in response to the official appeal for expansion it was hoped that an additional 1344 beds would be provided within a few weeks. The number of Red Cross detachments in the county was between 60 and 70, with a membership of 1869, of whom 1049 were on actual V.A.D. service, and 186 were working in military or naval hospitals. Upwards of 400 members had enrolled under the general service scheme. No less than 45 women had almost completed their training as stretcher-bearers, when they would release men at Netley Hospital for other work. About 150 men, unfit for military service, were relieving the disembarkation staff at Southampton.

**THE TRAINING OF THE DISABLED SOLDIER.**—The statement of Mr. Barnes in the House of Commons recently, on which we commented in our issue of March 17th, adds interest to an account of the training in the Queen Mary's workshops at the Pavilion Military Hospital, Brighton, which appears in the organ of that hospital, *The Pavilion Blues*, for March. After an experience of six months Mr. A. G. Baker, the superintendent of trades instruction, speaking of the maimed sailor and soldier, is convinced that many of these men may by suitable training be enabled to take their place as self-dependent citizens, if only they will give up a little of their spare time. The workshops are run on entirely voluntary lines, no other inducement being offered to attract the men than self interest. Strict discipline is enforced, and each student is expected to attend as regularly as medical treatment will permit, yet the conduct of the students has left nothing to be desired, while many of those who have obtained remunerative work have expressed their gratitude for the training received. This at present comprises commercial training, woodwork, elementary electricity, and motor engineering. Her Majesty the Queen has signified her intention of bearing the cost of a new building to which it is proposed to transfer the commercial training classes, and in their place it is proposed to instal leather trades and possibly tailoring. The field of selection has been widened by the co-operation of the headmaster of the School of Art, Brighton, and the principal of the Technical School. The workshops, which are registered under the new Act, rely upon voluntary contributions for their main support.

**MILITARY HOSPITAL MAGAZINES.**—The *Bulletin*, the official organ of the Third Western General Hospital (Cardiff, price 3d.) makes its first appearance, and as its contemporaries have done, prints accounts of the social activities of the hospital whence it emanates, with portraits of the staff and articles and illustrations, humorous and otherwise, of a topical nature. It is well printed and we wish it success, for the sales of these journals benefit those to whom the hospitals minister. The current issue of the *Ration*, the magazine of the Reading War Hospitals (Reading, price 2d.), maintains a good reputation, especially on the illustrative side, while the March issue of the *Craigleath Hospital Chronicle*, the organ of the Second Scottish General Hospital (Edinburgh, price 6d.), has among its contents a readable account of the Scottish Soldier of Fortune and the continuation of the story of the Gordon Highlanders.

## Obituary.

### JOHN MORTIMER, M.B. LOND., M.R.C.S. ENG., CONSULTING SURGEON, EXETER DISPENSARY.

Mr. J. Mortimer, who died at his residence in Exeter on March 9th, was the fourth son of the late Mr. W. Mortimer, J.P., of Exeter. He received his medical education at University College Hospital, London, taking his M.R.C.S. in 1876, and in 1877 graduated M.B. of London University. Mr. Mortimer practised in Exeter for many years, where he was highly respected. He was consulting surgeon to the Exeter Dispensary and on the honorary consulting staff of the Devon and Exeter Dental Hospital. He was also examining medical officer to the Devon Constabulary. At the commencement of the war he was attached to the Southern General Hospital, with the rank of Major, R.A.M.C. (T.F.), but ill-health compelled him to resign the appointment last year.

### ARTHUR EDWARD PERMEWAN, M.D. LOND., M.R.C.S., L.S.A., D.P.H. CANTAB., J.P.

Dr. A. E. Permewan died at his residence in Redruth, Cornwall, on March 21st, after a short illness. The deceased was a son of the late Dr. J. Permewan, of Redruth, and received his medical education at University College Hospital, graduating as M.D. London in 1883. He succeeded to his father's practice about 20 years ago and held numerous appointments, being surgeon to the Redruth Miners' Hospital, medical officer for the Redruth district, and medical officer of health for the Redruth rural district. For several years he was a member of the Redruth urban council and was a former chairman of that body. He was a member of the Cornwall Insurance Committee and a magistrate of the county of Cornwall. Dr. Permewan was held in much respect in Redruth and the district, and much sympathy is felt locally for his family.

## Medical News.

### UNIVERSITY OF DURHAM, FACULTY OF MEDICINE.—At the Second Examination for the degree of Bachelor of Medicine held recently the following candidates were successful:

*Anatomy and Physiology.*—Edgar Frederick Herbert Bell, Robson Christie Brown (second-class honours), Nan Coxon, Samuel Whately Davidson, Mark Julius Erberg, Alfred Stoddart Graham, Hamid Kamel, Malik Abdur Rahman Mansoor, Thomas Norman Vickers Potts, and May Raw.

### UNIVERSITY OF MANCHESTER.—At the examination for the Diploma in Public Health held recently the following candidates were successful:

T. C. Mackenzie and S. N. Mitra.

### UNIVERSITY OF LIVERPOOL.—At the examination for the degrees of Bachelor of Medicine and Bachelor of Surgery, held recently, the following candidates were successful:

Mikhail Azer, Constance Maude Edwards, Shaikh Mohamed Afzal Faruqi, Austin Jewkes Barlow Griffin, Isaac Jacob Lipkin (second-class honours), Robert Nixon, Charles Victor Pearson, Paul Barrar Pinkerton (second-class honours), Eric Strawson Stubbs (first-class honours), and Rattan Chaud Watts.

### QUEEN'S UNIVERSITY OF BELFAST.—At examinations held recently the following candidates were successful:

#### M.C.H. EXAMINATION.

John W. West.

#### M.B., B.C.H., AND B.A.O. EXAMINATION.

Joseph Adams, William L. Agnew (second-class honours), Samuel T. Alexander, Patrick Clarke, John H. Davison, William Harvey (second-class honours), James H. B. Hogg, Louis Jefferson, Robert N. B. McCord (first-class honours), William C. McCullough, Patrick J. McSorley, John Scott (second-class honours), and John Wilson (second-class honours).

#### THIRD MEDICAL EXAMINATION.

*Pathology and Materia Medica.*—John Barron, David Cromie, Thomas Dickey, Charles W. A. Emery, Stewart Fullerton, John Grimdon, Robin Hall, Samuel Hall, John M. Hosey, Joseph G. M. Leyden, William Napier, Jeremiah O'Kane, John B. Rea, and Andrew Watson.

*Materia Medica.*—Samuel Acheson, Thomas G. Campbell, Alfred E. Gallaher, Arthur H. Henry, George D. F. McFadden, William Michael, Hugh Paul, Henry Poston, Louis P. St. J. Story, Percival S. Walker, and Thomas Wallace.

#### *Pathology.*—Ruth M. Slade.

*Medical Jurisprudence and Hygiene.*—Crawford Blair, Thomas J. A. Connolly, David Cromie, Thomas Dickey, Daniel J. McDermott, Robert Nimmons, Charlotte Peplow, and Andrew Watson.

*Hygiene.*—Samuel Acheson, Thomas G. Campbell, Alfred E. Gallaher, Arthur H. Henry, George D. F. McFadden, William Michael, Hugh Paul, Henry Poston, Louis P. St. J. Story, and Percival S. Walker.

#### SECOND MEDICAL EXAMINATION.

*Anatomy and Physiology.*—Winifred W. Boland, Reginald N. Deane, Robert Duncan, David W. J. Gray, James S. F. J. Kerr, and Leonard G. Morrison.

*Anatomy.*—Helen M. Murnane.

#### D.P.H. EXAMINATION.

Mary G. Caskey and David L. McCullough.

### UNIVERSITY OF ABERDEEN.—At the graduation ceremony on March 23rd the following degrees were conferred:

*Doctor of Medicine (M.D.).*—James Clark Bell (honours for thesis) and George Riddoch (honours for thesis).

*Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).*—Wm. Francis Whitaker Bettsen, James Sutherland Balkwill Forbes,

\*Richard Ramsay Garden, \*Archibald Clive Irvine, \*Alex. Gow Lumden (second-class honours), Wm. Calthorpe MacKinnon, \*George Reid McRobert (second class honours), Charles Gordon Shaw Milne, Maggie Jane Moir, M.A., James Macdonald Morrison, Wm. Wyness Nicol, Frank Miller Rorie, Charles Shearer, Arthur Percy Spark, Robert Thom, Thomas David Watt, Jean Ordgarff Yule, and Vincent Thomas Borthwick Yule.

\* Passed Fourth Professional Examination with much distinction.

† Passed Fourth Professional Examination with distinction.

### THE RÖNTGEN SOCIETY.—The general meeting of this society, to be held at the Cancer Hospital on April 3rd, at 8.15 P.M., will be followed by a discussion on the Future of the British X Ray Industry, opened by Mr. Geoffrey Pearce, in which Sir J. Mackenzie Davidson, Professor A. W. Porter, F.R.S., Major Wilson, C.A.M.C., Dr. C. R. C. Lyster, and others will take part.

### DOCTORS OF MILITARY AGE: THE SQUABBLE AT OMAGH.—A correspondent writes: "The never-ending squabble about doctors of military age continues at Omagh, co. Tyrone. The latest phase has arisen from the fact that the Local Government Board refused to sanction payment, on the ground that he was of military age, to the doctor who has been doing duty for Dr. D. F. Murnaghan during the latter's illness. On March 24th, at a meeting of the Omagh guardians, it was, however, decided by 27 votes to 23 to pay the locum-tenant's account, £31 10s., and it remains to be seen what will be the final action of the Local Government Board on this disputed matter."

### THE HEALTH OF THE UNITED STATES ARMY.—The report of the Surgeon-General of the United States Army for 1916 dealing with the calendar year 1915 shows that the general health of the troops during that period was excellent, a matter which to-day assumes an importance quite outside its sanitary bearing. The number of men composing the army was approximately 100,000, distributed in varying numbers over a wide geographical area—namely, from the 66th meridian W. longitude to the 115th meridian east of Greenwich, and from the 64th degree N. latitude to within seven degrees of the equator, thus giving the medical officers in their capacity of sanitary advisers to the line an opportunity of studying the recent advances of modern preventive medicine under the most varied conditions. The non-effective rate for the entire army from disease alone was 20.85 per 1000, while from all causes it was 25.22, or a rate slightly higher than that for 1914, though still much below the rate for any preceding year except 1913, when it was 23.98. The death-rate of the entire army from all causes was 4.45, that from disease being 2.53. The discharge-rate from all causes was 14.06. Malarial fevers showed the lowest non-effective rate in the history of the army—namely, 0.54—the record in the Philippines being specially creditable as compared with former years. There were 8 cases of typhoid fever in the entire army with no deaths, all making good recoveries. Tuberculosis showed an admission rate of 3.49. In regard to venereal diseases, which in all countries are a very serious factor against military efficiency, it is pointed out that the measures adopted by the United States Army to limit its ravages include regular medical examination twice a month, prompt isolation, quarantining and hospital treatment, other measures being court-martial and stoppage of pay. Opportunities for study and sport, together with good food and clothing, have their influence, while earnest appeals are made on moral and ethical grounds. The admission rate for these diseases was 83.60 as compared with 89.84 in the previous year. The non-effective rate was considerably higher in 1915 than in 1914. Alcohol, which was banished from the garrisons, camps, and the navy before the war, says the Surgeon-General, must hereafter be held unqualifiedly antagonistic to military efficiency. The admission and non-effective rates for alcoholism have shown a steady decline, keeping pace with general public sentiment and the decreased use of stimulants in all walks of life in the United States.

## Parliamentary Intelligence.

### NOTES ON CURRENT TOPICS.

#### Criminal Law Amendment Bill.

THE Standing Committee of the House of Commons, to which the Criminal Law Amendment Bill has been referred, further considered it on Thursday, March 22nd.

Clause 7 extends the Indecent Advertisements Act, 1889. One of the provisions in the clause substitutes the following section for Section 5 of the principal Act:—

Any advertisement relating to syphilis, gonorrhoea, nervous debility, or other complaint or infirmity arising from or relating to sexual intercourse, and any advertisement which suggests, directly or indirectly, the use or taking of any appliance, drug, substance or thing, for the purpose of procuring miscarriage or abortion, or which suggests, directly or indirectly, that any premises are or can be used for immoral purposes, shall be deemed to be printed or written matter of an indecent nature within the meaning of Section 3 of this Act.

In the course of the discussion of this provision objection was taken to the wording on the ground that nervous debility in some cases arose from overwork and other causes with which the Bill was not intended to deal. A slight alteration was accordingly made in the text with the intention of making it clear that the complaints and infirmities enumerated were only those "arising from or relating to sexual intercourse." A proposal was made to include amongst the penalised advertisements those which suggested the use of any appliance, drug, substance, or thing, for the purpose of preventing conception. On it being pointed out that such a provision might overload the Bill and give rise to some opposition it was withdrawn.

The consideration of Clause 7 was resumed on Tuesday, March 27th.

An amendment was introduced making it punishable to issue an advertisement "which offered to give advice" relating to miscarriage or abortion.

Mr. GLYN-JONES moved as an amendment the insertion of the following subsection:—

Any person who holds out or recommends to the public by any public notice or advertisement, or by any written or printed papers or handbills, or by any label or words written or printed affixed to or delivered with any packet, box, bottle, phial, or other inclosure containing the same, any pills, powders, lozenges, tinctures, potions, cordials, electuaries, plasters, ungents, salves, ointments, drops, lotions, oils, spirits, medicated herbs and waters, chemical and officinal preparations whatsoever to be used or applied externally or internally as medicines or medicaments for the prevention, cure, or relief of any venereal disease, shall be guilty of an offence under Section 3 of The Indecent Advertisements Act, 1889. Provided that regulations may be made providing for the publishing or notification of the therapeutic properties and uses in connexion with the treatment of venereal diseases of any drug, medicine, or appliance in such manner and to such persons as the Local Government Board may direct.

The honourable Member said that it was the view of pharmaceutical chemists that the subject would not be sufficiently covered without this provision. At first Sir GEORGE CAVE was disinclined to accept the amendment, because he thought it would go too far. After some discussion he agreed to consider the matter before the Report Stage, and to take advice on it. In withdrawing the amendment, so far as the present stage was concerned, Mr. GLYN-JONES observed that if restrictions were to be put on advertisements of this kind, these restrictions must, in the interests of the honest trader, be made watertight.

Clause 7 went on to provide that—

Nothing in the Indecent Advertisements Act, 1889, as amended by this Act, shall apply to any advertisement by any local or public authority, or to any advertisement published in any bona fide medical or pharmaceutical publication or pharmaceutical trade list; and a person charged under that Act as so amended with publishing an advertisement, if he is not himself the advertiser, shall not be convicted if he proves that he did not know, and had no reasonable ground for suspecting, that the advertisement was of such a character as to make the publication thereof an offence.

Mr. GLYN-JONES moved as an amendment to strike out the greater part of this provision and to substitute words so that it should read:—

Nothing in the Indecent Advertisements Act, 1889, as amended by this Act, shall apply to any advertisement by any local or public authority, or to any advertisement the publication of which has been authorised in writing by the President of the Local Government Board or by one of His Majesty's Secretaries of State.

He said that he doubted whether anyone could give a good definition of what was a bona fide medical or pharmaceutical publication. He feared that if a person was infected with one of the complaints with which the Bill dealt he might turn to medical journals, where remedial preparations were advertised.

Mr. KING and several other Members expressed the opinion that in the matter of making known research work the provisions of the clause might operate in giving a monopoly to the medical profession.

Sir GEORGE CAVE said that the whole purpose of these provisions was to prevent public advertisements of information dealing with this subject being addressed to ignorant people. It was not desired to prevent bona fide inventors bringing remedies to the notice of qualified men.

Mr. DILLON: How do you propose to prevent the ignorant public having recourse to medical journals?

Sir GEORGE CAVE: I agree there is that risk, but I do not think the man in the street does buy THE LANCET or will buy it for this purpose. The danger was from advertisements in daily and weekly papers of quack remedies, which the sufferer used instead of going to consult a medical man. It would be a novel and undesirable plan to entrust the censoring of these advertisements to a Government department. He would, however, see his advisers as to whether there should be some provision against abuse in medical and pharmaceutical publications.

Mr. H. SAMUEL suggested that circularising should be substituted for advertisements.

Sir GEORGE CAVE promised to give careful consideration to the suggestions which had been brought forward.

The amendment was withdrawn and the clause as amended was agreed to.

#### Military Service (Review of Exceptions) Bill.

Mr. MACPHERSON, the Under Secretary for War, has introduced in the House of Commons a Bill "to enable the exception from Military Service of men excepted on the ground of previous rejection, or the previous relinquishment of, or discharge from, Naval or Military Service, or unsuitability for Foreign Service, to be reviewed." It has been read a first time.

#### HOUSE OF COMMONS.

WEDNESDAY, MARCH 21ST.

#### Commissioned Dental Surgeons.

Mr. MACPHERSON (Under Secretary for War) informed Sir Charles Seely that the number of commissioned dental surgeons in the Army was 454.

#### Classification of Men in the Army.

Speaking in Committee of Supply on Army Estimates, Mr. MACPHERSON said: I pointed out on a previous occasion that the accuracy of the examinations of the Royal Army Medical Corps and the various medical corps was an astonishing fact. It is the intention of the War Office—whether it will be carried into effect or not—to alter the classification of men. At present we have Class A, Class B, and Class C, and the various sub-classes in each of those categories. I understand that the proposal is now in favour at the War Office to alter the categories to two distinct ones—Class A and Class B. Class A will be very likely the class fit for general service and Class B those not fit for general service. At the present time I confess we have sent men of Class C 1 and C 2, who are supposed to be men to be utilised for labour at home, to France, but I understand that in each individual case a medical re-examination has taken place, and I understand that the medical authorities have given it as their opinion that the climatic conditions are in no way better and in no way worse here than in Northern France. I do not understand that, so far, any man in Class C 1 or Class C 2 has been sent to any theatre of war except Northern France.

THURSDAY, MARCH 22ND.

#### Poisoning Wells on Western Front.

Replying to Mr. BROOKES, who asked whether the War Office was in possession of any authenticated cases of water poisoning by Germans during the present operations on the Western front, Mr. MACPHERSON wrote: An official report has been received that the wells at Barleux, three miles south-west of Péronne, were examined and found to have been poisoned with arsenic.

MONDAY, MARCH 26TH.

#### Infantile Death-rate.

Answering Mr. O'GRADY, who put a question respecting the decline in the infantile death-rate to 91 per 1000 registered births, Mr. HAYES FISHER (Secretary to the Local Government Board) said: There is no foundation for the suggestion that the decline in the infant death-rate is due to the decline in the number of children who are vaccinated. The lower death-rate is not confined to districts in which vaccination is neglected, and at least one-half of the infants die before the age at which vaccination is usually performed. The decline in the infant death-rate is no doubt due to a number of causes, one of the most important of which is the valuable work which is now undertaken by local authorities and voluntary agencies for attending to the health of mothers and infants.

TUESDAY, MARCH 27TH.

#### Abdominal Operations at the Front.

Sir W. COLLINS asked the Under Secretary of State for War whether, having regard to the more mobile character

of the operations on the Western front and with a view to the earliest possible treatment of certain classes of wounds, especially those of the abdomen, the Army Medical Department was considering the desirability of using motor operating-theatres, similar to those supplied by the Wounded Allies Relief Committee to the Belgian and Italian armies.—Mr. MACPHERSON wrote in reply: The more mobile character of the operations on the Western front has been duly anticipated and the full equipment for an operating theatre, together with the temporary theatre itself, can be sent to the front with the personnel of a casualty clearing station wherever it is required in any part of the line.

## Appointments.

*Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

- BURNS, NEBBIT O'DELL, B.A., M.B., B.Ch., B.A.O. Dub., has been appointed Medical Officer and Public Vaccinator for the Huntspill District by the Bridgwater (Somerset) Board of Guardians.  
 EDWARDS, CHARLES, M.R.C.S., L.R.C.P. Lond., Medical Officer of Health for Bridport.  
 FELTHAM, H. G., M.B., Ch.B. Edin., Medical Officer of Health for the Port of Immingham, Grimsby.  
 VAN INGEN, MARY A., M.B., B.S. Lond., and TRACEY, VIOLET M., L.R.C.P., L.R.C.S. Edin., L.R.F.P.S. Glasg., Medical Inspectors of Public Health Department of L.C.C.  
 KEMP, C., M.B., C.M. Aberd., Certifying Surgeon under the Factory and Workshop Acts for the Morrison District of the County of Glamorgan.  
 KIRKMAN, ALBERT HENRY BRAUMONT, F.R.C.S. Edin., M.R.C.S., L.R.C.P. Lond., Medical Officer and Public Vaccinator for the Branscombe District by the Honiton (Devon) Board of Guardians and Medical Officer and Public Vaccinator for the Axminster (Devon) District of the Axminster Union.  
 POOLER, H. W., M.B., Ch.B., Medical Officer to Clay Cross, Grassmoor, Shirland, Somercotes, and Stonebroom Infant Welfare Centres, Derbyshire Education Committee; and District Medical Officer of the Chesterfield Union.  
 ROWLANDS, W. R., M.R.C.S., L.R.C.P., Medical Officer to the British Red Cross Hospital, Netley.  
 SHANNON, EDITH, M.B., Ch.B. Glasg., Resident Assistant Medical Officer at the West Ham Board of Guardians' Sick Home.  
 TOTTE, EDWIN JOSIAH, M.D., B.Sc. Lond., F.R.C.S. Eng., L.R.C.P. Lond., Acting Deputy Medical Officer of Health for Bideford (Devon).

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.*

- BIRMINGHAM CITY EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary £300 per annum.  
 BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £300 per annum, with apartments, &c.  
 BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Female House Surgeon. Salary £200 per annum.  
 BLACKPOOL, VICTORIA HOSPITAL.—House Surgeon. Salary £250 per annum, with board, &c.  
 BODMIN, CORNWALL COUNTY ASYLUM.—Female Junior Assistant Medical Officer. Salary £200 per annum, with board, &c.  
 BOLTON INFIRMARY AND DISPENSARY.—Senior House Surgeon. Salary £230 per annum, with board, &c.  
 BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Female House Surgeon. Salary £150 per annum, with board, &c.  
 BRISTOL ROYAL INFIRMARY.—House Physician and House Surgeon. Salary at rate of £120 per annum, with board, &c.  
 BURY INFIRMARY.—Junior House Surgeon. Salary £150 per annum, with board, &c.  
 BURY ST. EDMUND'S, SUFFOLK HOSPITAL, ANPTON HALL.—Resident Medical Officer. Salary £400 per annum, with board, &c.  
 CHARING CROSS HOSPITAL.—Resident Casualty Officer. Salary £100 per annum, with board.  
 CUMBERLAND, COUNTY OF.—Female Assistant Medical Officer. Salary £350 per annum.  
 DURHAMSHEIRE SANATORIUM FOR TUBERCULOSIS, WALTON-LANE, NEAR CHESTERFIELD.—Assistant Medical Officer. Salary £300 per annum, with board, &c.  
 DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant House Surgeon, unmarried. Salary £150 per annum, with board, &c.  
 EDINBURGH, ROYAL ASYLUM, MERRINGSTIDE.—Temporary Assistant Physician. Salary £265 per annum, with board, &c.  
 GENERAL LYING-IN HOSPITAL, YORK-ROAD, S.E.—Resident Medical Officer for three months. Salary £100 per annum, with board.  
 GUY'S HOSPITAL, S.E.—Female Clinical Assistant in the Venereal Department. Salary 1 guinea per session.  
 HAMPTON GENERAL HOSPITAL, HAVERSTOW HILL.—Casualty Officer for Out-patients' Department. One whole time, salary at rate of £160 per annum, with board; or two half-time at rate of £75 per annum each, lunch and tea provided.

- HARROGATE INFIRMARY.—Resident House Surgeon.  
 HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.—House Physician for six months. Salary 30 guineas.  
 LEEDS PUBLIC DISPENSARY.—Second Female Resident Medical Officer. Salary £200 per annum, with board, &c.  
 LONDON TEMPERANCE HOSPITAL, HAMPSTEAD-ROAD, N.W.—Assistant Resident Medical Officer. Salary £120 per annum, with board, &c.  
 MANCHESTER CORPORATION.—Assistant Tuberculosis Officer. Salary £350 per annum.  
 MANCHESTER, CRUMPSALL INFIRMARY, CRESCENT-ROAD, CRUMPSALL.—Locum Assistant Resident Medical Officer. Salary £8-8s. per week, with board, &c.  
 MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, PARK-PLACE, CHEETHAM HILL-ROAD.—House Surgeon. Salary £150 per annum, with board, &c.  
 NEWCASTLE UPON-TYNE EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary £300 per annum.  
 NORTHAMPTON GENERAL HOSPITAL.—Three House Surgeons. Salary £150 per annum each, with board, &c.  
 PECKHAM HOUSE ASYLUM, 112, PECKHAM-ROAD, S.E.—Medical Officer.  
 PORTSMOUTH COUNTY BOROUGH.—Tuberculosis Officer. Salary at rate of £500 per annum.  
 QUEEN MARY'S HOSPITAL FOR THE EAST END, STRATFORD.—House Surgeon.  
 QUEEN'S HOSPITAL FOR CHILDREN, HACKNEY-ROAD, BETHNAL GREEN, E.—Temporary Anaesthetist. Also House Physician, Casualty House Surgeon, and House Surgeon for six months. Salary £100 per annum, with board, &c.  
 READING RURAL DISTRICT COUNCIL.—Medical Officer of Health. Salary £100 per annum.  
 ROCHESTER, ST. BARTHOLOMEW'S HOSPITAL.—Clinical Assistant. Salary at rate of £110 per annum, with board, &c.  
 MOTHERHAM HOSPITAL.—Junior House Surgeon. Salary £250 per annum, with board, &c.  
 ROYAL FREE HOSPITAL, GRAY'S INN-ROAD, W.C.—Two House Physicians and Two House Surgeons. Salary £250 per annum, with board, &c. Also Junior Obstetric Assistant. Salary £22 per annum, with board, &c.; also care of 16 beds at Endleigh Maternity Hospital. Salary given. Also Assistant Anaesthetist. Salary £93 per annum. Also Female Senior Obstetric Assistant. Salary £23 per annum, with board, &c. Also to attend at Endleigh-street Maternity Hospital. Salary £60 per annum.  
 SHEFFIELD ROYAL INFIRMARY.—House Physician. Salary £120 per annum, with board, &c.  
 STOKE-ON-TRENT COUNTY BOROUGH.—Temporary Tuberculosis Officer. Salary £500 per annum.  
 WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—Resident House Surgeon. Salary £120 per annum, with board, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Lydd (Kent) and Robertsbridge (Sussex).

THE Secretary of State for the Home Department, Whitehall, S.W., gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for the Sheriffdom of The Lothians and Peebles, to be attached more particularly to the county of Midlothian. Applications should be addressed to the Under Secretary, Scottish Office, not later than April 15th.

## Births, Marriages, and Deaths.

### BIRTHS.

- ALEXANDER.—On March 20th, at Castle House, Riverhead, Sevenoaks, the wife of J. Finlay Alexander, M.A., M.D. Camb., of a son.  
 LAWSON.—At a private nursing home, Maribank, Dundee, the wife of Captain James Lawson, R.A.M.C.—a daughter.  
 QUACKENBOS.—On March 26th, at U.C.H., London, the wife of Maxwell Quackenbos, M.R.C.S., of a son.  
 SAUNDERS.—On March 25th, at Brown-street, Salisbury, the wife of L. Dimock Saunders, M.R.C.S., of a son.  
 SMEED.—On March 22nd, at Springfield, Netley, Hants, to Mildred, the wife of Captain Edward Smeed, R.A.M.C. (T.F.), a daughter.  
 WOOLLEY.—On March 22nd, at Lucknow, the wife of Lieutenant-Colonel J. Maxwell Woolley, I.M.S., of a son.

### MARRIAGES.

- EASTON—WHITE.—On March 22nd, at Wirksworth Parish Church, William Cochrane Calrnile Easton, Captain, R.A.M.C., son of the late George Easton, of Ayrshire, to Lillian Dorothy, third daughter of John H. and Mrs. White, of Alderwasley, Derbyshire.  
 HOOPER—ARMSTRONG.—On March 21st, at the Church of St. Mary the Virgin, Gillingham, Dorset, Reginald Arthur Hooper, Captain, R.A.M.C., to Daisy, daughter of R. B. Armstrong, The Hermitage, Gateshead-on-Tyne.  
 MAYBURY—JAMES.—On March 19th, at Christ Church, Woburn-sq., W.C., Captain A. V. Maybury, R.A.M.C. (T.F.), to Agnes Maud, second daughter of Mr. and Mrs. J. James, of West Haddon Lodge, Rugby.

### DEATHS.

- CLARK.—On March 13th, killed in action, William Brown Clark, M.B., B.S., Captain, R.A.M.C., aged 37.  
 LESLIE.—On March 20th, in London, after a long illness, Lucille Doxat Leslie, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg.  
 N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

### BOOKS OF REFERENCE.

IN spite of the difficulties of publication at the present time owing to conditions produced by the war, works of reference continue to appear with commendable regularity, though the date of publication is occasionally delayed. Among those which have recently appeared are *The Year Book of the Scientific and Learned Societies of Great Britain and Ireland* (London: Charles Griffin and Co. Price 7s. 6d. net), *The Public Schools Year Book, 1917* (The Year Book Press, 31, Museum-street, W.C. Price 6s. net), and *Herbert Fry's Royal Guide to the London Charities, 1917* (London: Chatto and Windus. Price 1s. 6d.). The first named is a record of the work done in science, literature, and art during the session 1915-16 by numerous societies and Government institutions, the information being compiled from official sources. In addition to the lists of papers read at the different societies, details are given as to officers, dates of meetings, conditions of membership, and publications. The number of pages dealing with biology, including microscopy and anthropology, is 46, with psychology 6, and with medicine 35, while economic science and statistics occupy 12 pages. The synopsis of contents, the arrangement of the societies, and the index make the task of reference an easy task.—*The Public Schools Year Book*, which is edited by Mr. H. F. W. Deane, librarian to the Dean and Canons of St. George's, Windsor Castle, and Mr. A. Bulkeley Evans, Barrister-at-law and secretary to the Headmasters' Conference, is an admirable guide to both parents and guardians, while it is at the same time the official book of reference of the Headmasters' Conference. The public schools are arranged in alphabetical order, and full information is given with regard to governing bodies, staff, nomination and admission, entrance examination and scholarships, as well as conditions of admission to the Navy, Army, Civil Service, and other professions. The Navy and Army sections have been brought up to date and include the regulations for permanent and temporary commissions which have been introduced owing to the war. A concluding section of the book gives a list of preparatory schools and a list of tutors.—*Fry's London Charities*, which is edited by Mr. John Lane, gives in alphabetical order the charities of London with their name, date of foundation, address, objects, and annual income. In the preface reference is made to the steadily declining birth-rate, and to the fact that while the advance of science has caused a fall in the general death-rate, that for young babies has hardly gone down at all, one-fifth of the deaths occurring in the first week, one-third in the first month, and nearly half in the first three months. Mr. Lane hopes that "a day will dawn when, for the first time in the history of the world, civilisation will honestly face the fact that its true wealth is to be found not merely in the treasure-houses of the great, but in the humble cradles of the labour that fills those treasure-houses. Europe will need all, and more than all, the children that are born within the next few years."

### THE RIGHT AND LEFT HANDS.

To the Editor of THE LANCET.

SIR.—With respect to the note in THE LANCET last week, under this heading, regarding muscular tremor in those unaccustomed to manual labour, I have found that holding in the hand a pear-shaped incandescent electric-light bulb containing a single filament shows rather well any tremors of the muscles, the quivering filament vibrating more or less vigorously according to the tremor, or emotion even. A sheet of fairly stiff paper horizontally held by one corner will show by its vibration of the opposite corner the state of the muscles. A cup of water will show tremor by its surface vibrations, and there are many other methods, apart from the scientific instruments employed by experts. Sedentary workers changing their employment to manual labour should learn the science of the implement. For instance, with the spade there is a right size, weight, shape, handle height, and form of tread or foot-piece (some adjustable) for the foot to be considered, and the right thrust and amount of material to be lifted at a time, and the right method of turning and throwing. These instructions are usually obtainable from old and experienced hands and those who have studied the knacks. The knowledge of the knacks must save fatigue in labour and make the work more expeditious. Some years ago in America a methodical foreman had to have cleared two large heaps of material. One lot was shovelled in the usual fashion and the other heap was removed by men using certain chosen shovels, holding and handling the shovel in a certain manner and taking certain quantities. The result

was all in favour of the methodical work. The proper resting of the limbs, alternately and in rotation, and the study of the pushes and pauses, must make a considerable difference to the result both to the worker and the work.

Again, the question of liquid refreshment during and after the work is no doubt a factor. Alcoholic drinks during manual labour do not suit everybody and only produce clogging effects on the muscles after the first spurt of work so occasioned has subsided, and will sometimes tend to prolong and increase any after-tremor. In the summer of 1872 it was necessary to shift the rails of 500 miles of permanent way on the Great Western Railway from broad to narrow gauge in a fortnight, and 3000 men did it working double time, with a record of health, and drank only skilly—a successful experiment. A ration per man was allowed of 1½ lb. oatmeal and ½ lb. sugar, and the cooks prepared it in buckets, the drink being taken round to the men with pannikins.

I am, Sir, yours faithfully,  
R. I. H.

March 26th, 1917.

### THE SUMMER TIME ACT.

In this country and on the Continent summer-time dates for 1917 have been arranged as follows: England, April 8th to Sept. 17th; France, March 24th-25th to Oct. 7th; Italy, March 25th to Sept. 20th; Holland, April 16th to Sept. 17th; Hungary, April 16th to Sept. 17th; and Germany, April 16th to Sept. 17th.

It will be seen that France and Italy have already started summer time, and to avoid confusion this should be remembered. Summer time will start in England earlier than last year, when it commenced May 20th-21st, and ended Sept. 30th-Oct. 1st.

### UGANDA HEALTH REPORT.

ACCORDING to the Blue-book of the Uganda Protectorate for the year ended March 31st, 1916, just presented to Parliament, the population of the territory is now estimated at 2,887,800. This total includes 963 Europeans, of whom 272 are females, and 3455 Asiatics (2809 males and 646 females). The conditions of general health during 1915 were satisfactory. The number of cases treated in Government hospitals and dispensaries showed a decrease to 77,467, with 203 deaths, from 90,730, with 298 deaths, in the year 1914. The number of European officials resident during the year was 481. Three were invalidated, bringing the total invalidated in the last five years to 18, the principal causes being nervous and mental diseases, blackwater fever, circulatory affections, and general debility. 532 Europeans (including officials) were treated at Government hospitals at Entebbe and Jinja, the principal diseases being malarial and alimentary.

Amongst the native population plague prevails mainly in the Eastern Province, although cases have occurred in other areas. The disease has increased in the Lango district of the Eastern Provinces, but its incidence elsewhere, where organisation for prevention is in force, has diminished considerably. The work of native inspectors, appointed to control both plague and small-pox and prevent the concealment of cases, has been beneficial, and rewards for the destruction of rats have been offered with good results in the Lango district. Inoculation of the general population in the endemic area with Haffkine's prophylactic was carried out only in Lango. Elsewhere, apart from a few hundred injections performed in Mbale and Soroti stations, inoculation was confined to military porters recruited from the endemic districts. The number of deaths reported from the three most infected areas are subjoined for the past two years:—

	1914.	1915.
Bukedi ... ... ...	1963	1912
Teso ... ... ...	651	615
Lango ... ... ...	624	951
<b>Totals ... ...</b>	<b>3238</b>	<b>3478</b>

The number of cases and deaths under the head of sleeping sickness have dwindled almost to a negligible quantity. The clearings made to exclude the tsetse fly from ferries and ports along recognised waterways have been maintained, but independent research has had to be postponed in consequence of the requisition of all available medical officers for military duty. The local situation necessitated the suspension of the bionomic investigations which have been conducted by Mr. W. F. Fiske for the past 27 months under the auspices of the Royal Society. It is hoped that these studies will be resumed after the cessation of hostilities, when it is anticipated that important practical experiments may be undertaken and the lessons derived from the investigations thus be carried to a satisfactory conclusion. The deaths attributed to sleeping sickness in 1915 in combined native and official returns were 352, as compared with 466 during 1914. Only 3 of these deaths occurred in Buganda Province, where, it may be recalled, the fatal cases in 1905 numbered 8003. Serious epidemics of small-pox took place in 1915-16 in the

Buganda and Eastern Provinces. In the former the strict measures adopted have practically stamped out the disease. The Eastern Province outbreak proved more widespread, and though the virulent stage of the epidemic has been overcome the disease is still prevalent in the Bugishu hills and, to a less extent, in the remainder of the Bukedi and Busoga districts.

#### THE PLYMPTON (DEVON) BOARD OF GUARDIANS AND MEDICAL RECOMMENDATIONS.

AN inquest was recently held at Brixton (Devon) relative to the death of a married woman. It was stated that the medical officer ordered beef-tea for the deceased, but the guardians would not allow it. The husband earned 23s. weekly and had nine children to provide for. The coroner remarked that the guardians incurred a grave responsibility in refusing the doctor's orders, and had the medical man only said that death had been accelerated by want of the nourishment their position would have been serious. The jury returned a verdict in accordance with medical evidence and added a rider to the effect that the "guardians' conduct was scandalous," and expressed a hope "that in future more care would be taken."

#### SCHOOL-BOYS' CHEMICAL EXPERIMENTS.

BEFORE Mr. Justice Darling and a special jury recently a case was tried in the High Court in which a school-boy, A. C. Askew, suing through his father as his next friend, claimed damages against the Middlesex County Council, as the county education authority, for personal injuries due to the alleged negligence of the defendants. Young Askew with other boys formed a class under the charge of Miss Rollinson, a Bachelor of Science of London University and a lady with 17 years' experience as a teacher. The boys were directed to place a certain quantity of sawdust on crucible lids to warm it, and having been given small quantities of nitric acid in test-tubes, to drip the acid on to the sawdust, using glass tubes as drippers, which they had to fetch from a drawer. For the purpose of their experiments they were divided into groups of three, one of whom would perform the experiment. One of the other boys in the plaintiff's group was looking for a tube when another boy said that the sawdust was ready, so, instead of waiting, the boy who should have found the dripper poured some of the acid from his test-tube on to the sawdust, when a violent action took place, causing disfiguring injuries upon the plaintiff's face. The evidence called on his behalf, apart from the evidence of fact, was to the effect that Miss Rollinson should have performed the experiment herself, as it was a demonstrator's experiment, instead of which she was engaged upon other work in another part of the room, and that charcoal should have been used instead of sawdust. It was also suggested on behalf of the plaintiff that the boy who handled the tube containing the nitric acid was known to be mischievous. Evidence was given on behalf of the defendants to the effect that the experiment was a proper and safe one in the circumstances, and that from an instructor's point of view it was much better to let boys conduct suitable experiments themselves than to demonstrate before them. It was submitted on behalf of the defendants that there was no evidence of negligence to go to the jury, but Mr. Justice Darling declined to withdraw the case from the jury on that ground, and eventually a verdict was found for the boy for £250 damages, and his father, who claimed compensation for the expense of medical attendance on his son, was awarded £25. Mr. Justice Darling gave judgment for these amounts, but granted a stay of execution with a view to an appeal.

**A. B. J.**—Any man who has signed a year's contract has the right to come out of the Service at the termination of the contract. But if he was under 41 at the time when the Military Service Act was passed he becomes liable under that Act, and therefore, of course, can be taken as a combatant. If immediately upon coming out he enrolls with the Central Medical War Committee (under Army Order 485 of 1916) he can be taken for the Royal Army Medical Corps after consultation with the Committee. The agreement with the Committee is in such cases to give the man a month's notice of the date on which he will be called up. Up to the present the Central Medical War Committee has not called upon any man to re-enter the Service unless he has been at home at least a year.

The following journals, magazines, &c. have been received:—*Jurnal d'Urologie*, Dublin; *Journal of Medical Science*, *Revue d'Hygiène et de Police Sanitaire*, *Archives Médicale et Pharmacie Navale*, *Birmingham Medical Review*, *Canadian Practitioner and Review*, *Dominion Medical Monthly*, *American Journal of Medical Sciences*, *Mercy and Truth*, *Medical and Legal Journal*, *American Journal of Obstetrics*, *American Journal of Surgery*, *Surgery*, *Gynecology and Obstetrics*, *Medical Journal of South Africa*, *Ophthalmology*, *Annals di Medicina Navale e Coloniale*, *Interstate Medical Journal*.

## Medical Diary for the ensuing Week.

### SOCIETIES.

MEDICAL SOCIETY OF LONDON, 11, Chandos-st., Cavendish-sq., W.

MONDAY.—8.30 P.M., Discussion on the Treatment of Arterio-Venous Aneurysm, opened by Col. G. J. Symonds, R.A.M.C., O.B., and Major R. H. Jocelyn Swan, R.A.M.C.

RÖNTGEN SOCIETY, at the Cancer Hospital (Free), Fulham-road, S.W.

TUESDAY.—8.15 P.M., General Meeting.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Partoe: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Partoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics.—10.30 A.M., Surgical Out-patients (Mr. H. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham); Gynaecological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynaecological Operations (Dr. A. H. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. H. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

MONDAY.—5 P.M., General Monthly Meeting.

### METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, March 28th, 1917.

Date.	Main-fall.	Solar Radio in Vacuo.	Maxi- mum Temp. Shade.	Min. Tem.	Wet Bulb.	Dry Bulb.	Remarks.
Mar. 22	...	73	41	31	32	33	Cloudy
" 23	0.03	66	40	30	32	33	Snowing
" 24	0.04	73	45	28	30	31	Fine
" 25	...	65	49	31	36	37	Overcast
" 26	0.04	77	44	37	39	40	Raining
" 27	0.03	74	42	31	32	34	Cloudy
" 28	0.05	62	45	33	34	36	Overcast

Other information which we have been accustomed to give in these "Readings" is withheld for the period of the war.

### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To the EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

## MANAGER'S NOTICES.

## ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8d. The rates of subscription remain as revised in October.

## TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

## TO COLONIAL AND FOREIGN SUBSCRIBERS.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

Subscribers abroad are particularly requested to note the rates of subscription given on page 4.
